PREFACE.

This year has been less remarkable for great events than for the steady and gratifying progress which has been made in every branch of the two professions, to recording the labours of which our Journal is devoted. The financial embarrassment of the country, and the course of political events, have been far from favourable either to the promotion of existing undertakings, or the formation of new ones. With regard to architecture, it must have been gratifying to our readers to have witnessed the increasing interest which has been shown by the public of late years on this subject, manifested by the demand for competitions, and the extended discussion of architectural topics in the higher class of general periodicals, while a strong feeling seems to prevail as to the necessity of enlightening the public mind, and bringing it to bear upon this as upon other branches of the arts. Architecture has at last been recognized as a subject for collegiate education, by its introduction into King's College, and by the formation of architectural schools in the national dockyards. The Royal Academy has given signs of a more liberal disposition towards the profession, by the election of Barry, notwithstanding his known connexion with the Royal Institute—a step highly important. The Institute of Architects of Ireland has been established, and the royal patronage bestowed upon it. The Revival style, as we announced last year, has now gained a footing in this country, at the same time that considerable progress has been also made in internal decoration by Parris, Latilla, Owen Jones, and other artists of talent; so much better disposition is now shown to unite this branch of the arts with architecture, that there appears every prospect of the Houses of Parliament being painted in fresco, although we hope not, as has been suggested, by foreign hands. The temple of English freedom should never be desecrated by strangers.

We have not this year, as previously, to regret the loss of many great edifices, although York Minster has suffered considerably by fire. Among the ancient buildings in which restorations or improvements have been carried on, may be mentioned Westminster Abbey, the Temple, St. Aldate's, York Minster, Thorney Abbey, St. Mary Nottingham, St. Michael's Basingtoke. Few buildings of any note have been completed, although many are in a satisfactory state of progress; we may, however, mention the Reform Club, the Club Chambers Association, the Princess's Theatre, and the Manchester Unitarian Chapel. Several fine railway stations have been erected, and cemeteries opened in London and different parts of the country. The subject of a change in the system of prison discipline now in agitation, seems to promise, at an early period, extensive employment for the profession, as also the question of national education, and the construction of school-houses consequent thereon. The profession in Ireland has been largely employed in building union workhouses, some of which are on a large scale; a prospect also exists of similar employment for our Scotch brethren. It will be a matter of gratification to consider that the important question of the architectural and sanitory police of large towns is now attracting much attention. Something therefore may be expected to be done.

Among the architects whose loss we have this year to regret, are Sir Jeffry Wyatville, Albertolli, and Mr. Whitwell.

The engineering profession although having greater obstacles to contend with than the architects, have shown rather more vigour, and will require therefore a more lengthened statement of the progress they have made. Engineering education is making still greater advances, a new faculty has been established at Glasgow, and the first Regius Professor of Engineering appointed, the other faculties have been improved; at King's College the architectural instruction has been extended, and a lower school formed for elementary instruction. To the Mining schools we shall hereafter have occasion to advert; we may farther mention the increased qualifications required of enginemen by the Admiralty, the examination of officers on the steam engine, and the delivery of lectures at the Royal Naval College, the establishment of a College for Civil Engineers at Putney, and the project of a School of Practical Engineering at the Polytechnic Institution. While at this point we may mention that honorary degrees have been conferred by the universities, upon several engineers, and also upon Junius Smith, the great promoter of Atlantic Steam Navigation. The University of Edinburgh have ordered from Chantrey, a statue of Watt, being the sixth of that great man, and the Institute of Civil Engineers have this year offered premiums for memoirs of eminent engineers; we regret however, to remark, that no disposition has been shown by the Government to bestow the same honours upon this as upon other professions. Prizes have been awarded by an Association at Glasgow, for improvements in safety valves. The local exhibitions of arts and manufactures have acquired this year still greater extension, and probably we shall not long wait for a national exhibition in the metropolis.

The railway system has in several ways prominently attracted public attention. We shall first advert to the number of lines which have been this year either wholly or partially opened. Among these are, the Great Western, Brighton, Blackwall, Eastern Counties, Northern and Eastern, North Midland, York and North Midland, Manchester and Leeds, Hull and Selby, Glasgow and Ayr, Glasgow and Paisley, Maryport and Carlisle, Preston and Wyre, Lancaster and Preston, Chester and Birkenhead, Chester and Crewe, Manchester and Birmingham, Birmingham and Gloucester, and Taff Vale. On nearly all the great lines most fearful and unprecedented accidents have within the last few months taken place without any satisfactory cause for their extent, they seem indeed to be the result of a similar mysterious visitation to that by which steam navigation was afflicted last year and the year before, and from which it has been this year free. Government have been as usual meddling this year, and we regret to say with greater success than before; besides employing parliamentary committees and itinerant commissioners who have been employed on the Scotch and Holyhead routes, an act has been past for giving the Government an unprecedented control over the lines. Only one bill for a new railway passed last session. The system of leasing small lines to other companies, and of the union of lines has been much extended. Rope traction has now been shown on a considerable scale on the Blackwall railway, on which wire rope is proposed to be used, and a large experiment has been made of the pneumatic system, on the West London Railway. Electric telegraphs have received some improvements, and their utility for railway purposes may now be considered as finally recognized. The French government have this year shown a better spirit as to the railways, but they make but small way, the Paris and Rouen projectors have however raised large sums in this country. The Russian government have sent an engineer to this country to prepare for the formation of railways in Russia on a large scale, and it may be observed that generally the European nations are making progress as to the introduction of the system.

The use of wood pavement for the streets has greatly extended both in London and the provinces, and the use of asphalte also seems to be established. Measures are in progress for running locomotives on common roads.

The appointment of commissioners for inquiring into the state of our coasts, has been a measure long called for by the mercantile interests of this country; but whether the recent labours of the harbour commissioners will either prove satisfactory or useful, yet remains to be seen. During the year improvements have been made at Leith, Fleetwood-on-Wyre, the Bute Docks at Cardiff, Ramsgate, Rye, and Woolwich. In this latter establishment we may also call attention to the introduction of the steam machine for making shot. At Granton a pier has been erected; in the Downs a safety beacon on a new principle; and this year we have seen the first application of the screw pile system to the erection of a lighthouse at Fleetwood-on-Wyre. Considerable attention has been devoted to the embankment of the Thames, into which subject Parliament has inquired; the river works of the new Houses of Parliament have been completed, and hopes are entertained that either by the city or goverment, works will be carried on so as to improve the whole north bank of the river; an extensive embankment on the shores of the Thames and Medway has been made by Lord de Vesci. The propositions for draining the Lake of Haarlem, and for recovering land in Morecambe Bay and the Wash, have caused many engineers to direct their inquiry to improvements in draining, as far as regards the application of mechanical power to such purposes. The Chard and the Ulster Canals have both been opened, and some extensive works completed on the Hereford and Gloucester. The repairs of Blackfriars Bridge have been satisfactorily ended, while great progress has been made with those carried on at Westminster Bridge; some majestic viaducts have been constructed on the railways. The application of Rendel's system of floating bridges has been extended to Portsmouth and Calcutta.

The interests of steam navigation having been seriously threatened by the proposed application of stringent government measures, we considered it our duty to awaken the attention of the marine engineers to the subject, and we congratulate our readers on the success which attended our efforts, such a union of the profession having been organized, and such effective measures taken, as to compel the authorities to postpone the intended bill. The importance of steam ships as a part of our marine, has been shown by recent hostile events, when the agency of this arm, both in Syria and China, has been so exerted. The government have shown their sense of it by giving higher rank and privileges to the enginemen in the naval service, by directing schools for their instruction to be formed in the dockyards, and by making an acquaintance with the marine engine a part of the studies of the superior officers. The French government have greatly enlarged their engine factory. The investigation of the properties of the Archimedean screw has been continued, and its utility recognized, at the same time that the question of modes of propulsion has been the subject of extensive experiment. The application of propellers to sailing vessels, as in the Earl Hardwicke and the Vernon, has been successful. The introduction of steam navigation on canals, has also tended to direct attention towards propellers, and to the use of iron as a material for steam canal boats and for passage boats, of which the Lee, the Nonsuch, and the Alice are examples. Iron has been so extensively used as a material of construction for steam boats, as already to have given a great deal of employment to marine engineers. Abroad, iron steam boats have been introduced on the Danube and the Elbe. Iron has been applied considerably for constructing sailing vessels; it has also been used for a floating fire engine. The experiments continue on the application of electro-magnetic power to navigation, but with no tangible result. Steam navigation has, this year, been greatly extended; Fleetwood-on-Wyre has been added to the steam ports; the Mediterranean service has been more efficiently organized; in the Atlantic the number of steamers to the United States has been increased, and a line to Boston established, communication with Madeira has been opened; in the Pacific, steamers are now running along the western coasts; in India, increased means of communication with England still occupy the public mind; attention has also been directed to the capabilities of the Indus and its tributary streams.

Mining is greatly advancing as one of the branches of the profession, or a branch likely to be promoted by the measures taken for giving instruction in it. The munificence of Sir Charles Lemon has established in Cornwall a special school for mining, and professorships also exist in King's College, London, and at Durham. Instruction in mineral chemistry, so much required, has been promoted by the establishment of the government school attached to the museum of economic geology, and by the courses delivered in several public institutions. The powers of Cornish engines have been the subject of serious discussion among our engineers, and the attention of the Dutch government has been directed to them to ascertain their applicability for economical draining.

Among the engineers who have been this year lost, we have to mention with regret, Sir Robert Seppings, Lieut. Thomas Drummond, and Mr. Hazeldine, an engineer employed on the Menai and Conway bridges.

Having thus disposed of the interests of our readers, it remains that we should ask their indulgence while we recall to them the exertions we have ourselves made in fulfilling our duties towards them. For this we appeal with confidence to the volume just concluded, where they will find that our correspondence has increased in value and interest, and that no exertion or expense has been spared to render the work worthy of the increased patronage it receives. Our readers will find in it 432 pages, 24 plates and 214 engravings, forming a mass of information which, for value and for cheapness, is not surpassed by the periodical works of any profession. Such have been our endeavours in our communication with the professions through the medium of these pages, but we have not hesitated, neither shall we, to exert ourselves for them, when and where we may have it in our power, by acting in a public capacity. Such we considered to be our duty on the steam navigation question, as we shall on every occasion where the interests of the professions require it, and our humble efforts can in any capacity be exerted in their defence.

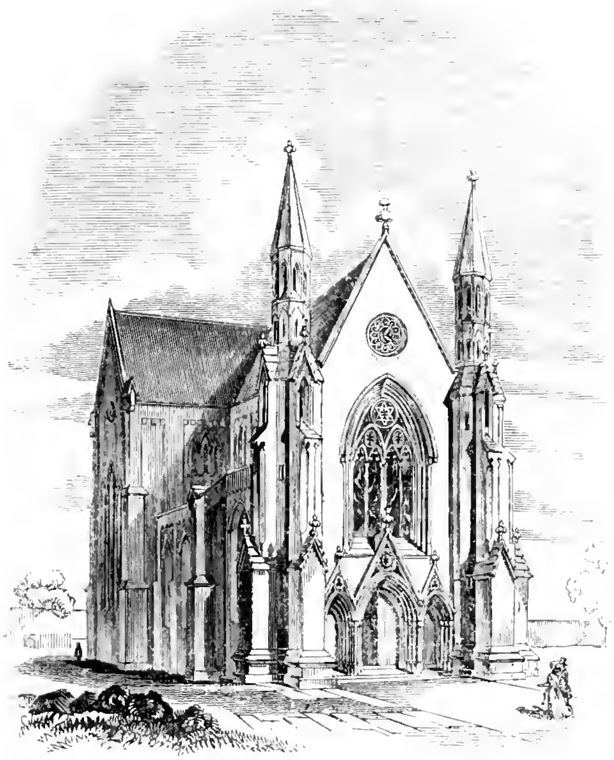
THE

CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

PRESBYTERIAN (UNITARIAN) CHAPEL AT DUKINFIELD.

Mr. R. Tattersall, Architect.



ECCLESIASTICAL EDIFICES.

It is our intention under this title to give illustrations and descriptions of such new edifices dedicated to religious purposes, respecting which we can obtain information. We hope that this may serve as a stimulant in directing public attention to this now neglected subject, and particularly in rousing the self-esteem of members of the establishment. At present those entrusted with the erection of churches seem to consider it their first object to make as much pew room as possible, regardless of all other objects, on much the same principle as they would construct sheep pens—crowd the animals in, and care nothing for their comfort. Why does the church appeal so powerfully to the beautiful monuments built by our ancestors, why does she depend on that devotional feeling which the contemplation of our hallowed sites suggests, if she herself thinks it beneath her to keep up the dignity of the estate she has inherited. Oh! how eloquently can her ministers dwell on the solemn thoughts inspired by the long drawn aisles of our ancient cathedrals, how energetically can they remind us of our childish predilection for the ivy covered spire! but when it comes to the expenditure of the vast sums under their control, how totally do they neglect their favoured dogmas, how selfishly do they consult their own interests at the expense of the establishment of which they are members! Empirics are employed, the men who can do the dirty work cheapest, nothing is allowed for architecture, nothing for the decorative arts—the worthy pastors think they best consult the wishes of their flocks by making the sheep pens as numerous as possible. They totally forget that it is not their own money they are expending, but the produce of public grants or private benefactions; that they are only trustees, and that they are not to look to their own interests only, but pay some regard to the purposes for which the sums were received, for surely it is more gratifying to the donors to see a handsome edifice rather than the barn-like structures with which the public have been of late so abundantly annoyed. A Union Workhouse would beat most of the new churches hollow in almost every point of its construction. We can only say that unless the members of the establishment reform their system, they will be beaten by the other religions, Jews, Catholics and Dissenters all surpass them in elegance and costliness of construction, and surely their necessities are not less, nor their revenues more abundant. We regret indeed that one of our first examples, the Unitarian Church at Dukinfield, should be the work of Dissenters, and a shame to the dispensers of the public money. Sure without any parliamentary funds, without any rich endowments, and with but a small portion of the wealth of the nation, first rate talent has been employed, and a noble monument erected.

B

Dukinfield Chapel.

This chapel is now erecting on the site of the former edifice, (whose dilapidated condition and inadequacy in supplying room for the large congregation assembling therein, rendered the erection of a new and more commodious building absolutely necessary,) from the designs of Mr. R. Tattersall of Manchester.

The style of architecture which has been adopted for the structure now in progress, is that which prevailed at the commencement of the fourteenth century, when our architects began to add refinement in the details to the many beauties which characterise their works, and to introduce those changes in the early English style which immediately precede and ultimately form and distinguish the decorated style.

The plan of the chapel is cruciform, with a lofty nave and transepts lighted by clerestory windows, the nave having aisles lighted by lancet windows. The east and west ends of the nave project beyond the ends of the aisles; in the west projection are the principal entrances with a children's gallery over, whilst the east projection contains the vestry and private entrance with a gallery over affording ample room for a powerful organ and numerous choir.

The principal elevation into which it has been thought advisable to introduce whatever decoration might be used, consists of two octagonal turrets flanking the west wall of the nave, strengthened by massive double buttresses in three stages, the lower part terminating in weathered canopies, the middle having weathered offsets, and the upper being formed into niches, surmounted by canopies, uniting with the weathering of the turrets, and the parapet moulding of the west gable. The lower and upper canopies to the buttresses, are terminated by appropriate finials. At the termination of the buttresses the turrets become isolated and are continued in two stages to the base of the pinnacle, the lower stage having shafts at the angles with moulded bases and capitals supporting pointed arches, and in each face of the octagon is a narrow slit or opening in the form of the ancient *ballistraria*, whilst the upper stages have plain shafts at the angles, with a narrow lancet opening, having the tooth ornament in the hollow surrounding the same, on each face of the turret. The turrets finish with lofty pinnacles having shafts at the angles, and terminating in finials, the highest part of which will be 73 feet above the surface of the ground. One of these turrets will contain a bell, and the other is to serve for the clock weights. The turret in which the bell is to be suspended will contain a winding staircase for access to the clock-room in the roof the nave.

Between the turrets to the west front are three doorways forming the principal and gallery entrances to the chapel. These are boldly recessed, the centre door being much wider than the side ones, and are formed into one group by the arrangement of their shafted joints, moulded archivolts and the triangular canopies with which they are surmounted. The moulding over each canopy, unites with the hood moulding of each door, and terminates upon carved heads, whilst the apices of the canopies finish with carved finials, the centre one being quite isolated in the opening of the window over. Each canopy is filled in with deeply cut tracery. In the hollows of the arched heads and between the shafts of the jambs, it is intended to introduce those very effective enrichments, known as the ball flower and leaf ornament and the tooth ornament. The three doors will be of oak, relieved by the quaint and beautiful ramified iron scroll-work so characteristic of this style of architecture. Immediately over the doors is a four light window formed with shafted mullions and jambs, and filled in with the rich and elegant tracery, which we find immediately preceding the flowing lines of the decorated style. The ball flower and tooth ornaments will be introduced into two of the hollow mouldings of the jambs and head, and the window will have a hood moulding terminating on carved heads. Above the window, and in the gable of this front will be placed the clock dial, which it is intended eventually to make transparent. This is in the form of a multifoil surrounded with bold mouldings, and in the intervals of the cusps will be placed the figures of the dial. The gable of this front which is very lofty, (as are all the others owing to the high pitch of the roof), is surmounted by a richly carved finial, and in the mouldings of the parapet the ball flower ornament is again introduced. The whole of the plain ashlar to this front is to be neatly tooled, but the moulded work and dressings are to be rubbed or polished. The remaining fronts of the building are of a much plainer and simpler character, and are to be faced with neat hammer dressed walling stones, the dressings being tooled. All the exterior of the chapel is to be faced with the best Yorkshire stone.

The sides of the aisles are divided into compartments by buttresses of an early character, having a single off-set, and uniting at the top with the parapet, which is supported between them by quaintly cut corbels, and finishes with a tablet or coping formed by the moulded cast-iron gutter. In each compartment of the aisle are plain lancet windows, with neat hood mouldings terminating on carved heads. The transepts project some little beyond the sides of the aisles, and there external angles, as well as those to the east end of the nave, are flanked by plain buttresses of a similar character to those of the aisles, and divided into three stages with plain off-sets. The three gables are covered by a plain coping, terminating in canopies at the lower ends. In the gables to the transepts and east end of nave are openings for light and ventilation to the roof, and the same kind of corbels are introduced to support the parapet as are used to the aisles. In the end of each transept are triple lancet windows united together by their hood mouldings, the centre being higher than the side ones. The clerestory is divided into compartments by flat buttresses ranging with those to the aisles, surmounted by a parapet and coping of a similar description to those already mentioned. In each compartment are triple lancet windows having hood mouldings terminating on carved bosses. The principal entrance door opens into a porch or vestibule formed between the two staircases to the galleries, from which it is separated by screens ornamented with tracery, and having doors of communication. From hence, inner folding-doors open directly into the body of the chapel, which is divided as before described into nave and transepts, the former being flanked by aisles from which it is separated by light piers formed of clustered shafts, supporting on richly moulded pointed arches the clerestory walls, in which there is a narrow lancet window over each compartment. The aisles are also open to the transepts from which they are separated in like manner. The galleries will extend across the west end of the nave over the aisles and across the transepts. The nave and transept ceilings are to be groined throughout with moulded ribs on all the intersections of the vaulting, and against the walls, springing from corbels formed by clustered shafts affixed to the clerestory walls. The ceiling to the aisles is to be formed into neat plain panels. A neat screen extends across the east end of the nave in a line with the ends of the aisles, separating the vestry from the chapel, against which is to be placed the pulpit, to be entered from the vestry through an opening therein. The pulpit will have a highly enriched canopy or sounding board, and the whole is made to harmonize with the screen and the general character of the building. Around and beneath the pulpit, which is supported by a cluster of shafts, is the space allowed for the communion altar on a raised platform enclosed by a neat railing. Beyond the screen and over the vestry is the organ gallery, and it is intended that the front of the organ-case shall be made to assimilate with the screen as much as possible. At the opposite end of the nave, and over the principal entrance is a gallery capable of containing upwards of seventy childre, leaving an uninterrupted view of the four light window in the west front. Vaults are formed under the west entrance, and there is a cellar under the vestry for warming the chapel with hot water.

The extreme length of the building will be 94 feet, and the width across the nave and aisles 50 feet, that across the transepts 61 feet.

The chapel will contain sittings for 977 persons, 194 of which are free. It s expected that it will be completed and ready for divine service towards the latter part of this year. The cost of its erection will be defrayed by subscription.

HISTORY OF BRITISH ARCHITECTURE.

Mr. Editor—Being anxious to make myself acquainted with the history of architecture in this country, I regret to find how inadequate are the records hitherto collected by writers on the subject, to enable one to form an accurate conception of the vicissitudes of the art in England. This has excited in me the desire to collect such materials on the subject, as may be useful to my professional brethren. I beg therefore to appeal Sir, through you, to all parties who may have any information to give of men of such standing as Vanburgh, Hawksmoor, Gibbs, Carr of York, Morris of Bath, Kent, Gandon, Taylor, Chambers, Dance. I shall feel much obliged either by being referred to sources of information, or by being furnished with the lists of the works which such men as these may have executed. I of course confine myself to no period; on the contrary, I would wish to embrace the earliest, as well as the most recent, epochs of the history of English Architecture.

I am, Sir, very faithfully, your's,

Thos. L. Donaldson.

7, Hart Street, Bloomsbury Square,
December 20, 1839.

South-eastern Railway.—The rapid progress of the works of the South-eastern Railway is giving quite a lively aspect to Folkestone. The bridge across the Canterbury and Dover road is also completed; and the advancement of the line on either side is going on in a highly satisfactory manner. —*Dover Chronicle.*

CANDIDUS'S NOTE-BOOK.
FASCICULUS XII.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. From all the views and drawings I have ever seen of Abbotsford, I always considered it to be a very trumpery specimen of architecture, but I was not before aware of the exceedingly whimsical taste of Sir Walter Scott, until I saw the view of the dining-room given in the ninth volume of Lockhart's Life of him now publishing. Will it be believed that that dining-room contains one of the oddest and most impertinent pieces of furniture imaginable for such an apartment? Had it been a Rumford cooking apparatus or something of that kind, its convenience might have excused its oddity and homeliness, but what shall we say to a four-post bedstead in a dining-room? There certainly is no accounting for tastes; and the idea is a sufficiently original one. Perhaps it was intended as a refinement on the Roman mode of lying recumbent at table upon couches. But I trust that no one will think of imitating Sir Walter in that particular fancy of his, or people will henceforth strip and get into bed, instead of sitting down, to table. At least that should be a privilege exclusively confined to persons of genius,—not extended to ordinary mortals, good reader, like you and me. Well, there certainly must have been comical doings at Abbotsford, if such was the custom of the place: and we insignificant nobodies may be very well content with dining-rooms without beds in them.

II. The Abbotsford dining-room reminds me of the Scott Monument at Edinburgh. How is that getting on?—or how happens it that we hear no more about it? Is it, like the Edinburgh Parthenon, the monument of a monument that was to have been; or like the Nelson Monument in Trafalgar Square, altogether an imaginary, immaterial fabric. Certes, monuments are not things of mushroom growth.

III. We are, now it seems, all at once going to be filled with admiration of Inigo Jones; which is passing strange, considering that they abound with the very faults that are found unindurable when they occur in modern buildings. With what consistency of taste, those who are shocked at the impropriety of half columns and broken entablatures, can affect to see any supereminent beauty in his building at Whitehall, which has the further impropriety of an upper order above a lower one,—it is for them to explain. Possibly,—since they cannot but allow that the circumstances just referred to are egregious defects in themselves, they will assert that there are merits and excellences in his designs which amply atone for all their blemishes,—not to call them vices. That such is really their opinion must be taken for granted; but then, wherefore do they not vindicate themselves from the appearance of inconsistency, by plainly discriminating between the defects they reprobate and the beauties they admire, and informing us in what the latter consist? Or are we to suppose, that they are of the sort of critics extolled by Sterne for being pleased they know not why, and care not wherefore:—for which in my opinion no very great power of criticism is required? Perhaps Sterne was thinking at the moment, only of the kind of critics he himself wished for,—and there are othe s besides him, who look more to the quantity than the quality of the praise they get, but for my own part I would rather obtain the approbation of one critic who could tell why he bestowed it, to that of a score of others whose compliments seem to have no meaning, consequently carry with them no proof of sincerity.

However correctly and exactly general principles may be laid down, they can never be made to comprehend every specific application of them; but there will invariably be, more or less, something that, although based upon them does not obviously appear to conform to them, nay perhaps may seem at variance with them, on which account those who are not acquainted with the mysteries of art, becomes perplexed, and are at a loss to know whether they ought to censure or are at liberty to admire. It becomes the duty of criticism, therefore to elucidate such apparent contradictions, and in every particular case, to explain how it happens that the disregard of certain established rules may have been attended with beauty, or, *vice versa*, how the adherence to them has failed to secure it:—again, to point out wherein frequently consists the very great difference between two buildings, very similar as to style and design, yet altogether unlike in regard to the impression they make.

IV. Very far more stress than ought to be, is generally laid upon simplicity of plan. For my own part, I very much question it being a merit at all, when I perceive that so far from conducing to any beauty, it generally constitutes a defect, inasmuch as it excludes all variety and combination, together with contrivance. While it leaves nothing to the imagination, it does not present itself to the eye as a beauty the entire plan not being seen at once; nor do I understand what particular pleasure can be afforded to the mind, by knowing that with regard to the distribution and form of the several rooms there is nothing more than what has been seen over and over again. Nay, I will not be quite sure that I understand what is meant by simplicity in such cases: yet if it be meant that the plan is such that any stranger can at once comprehend every part of it, by merely going over the building at a single time, should say that so far there would be very little to approve or admire;—certainly no evidence of skill or ingenuity, and very little of either picturesque effect, contrast or variety, because where they do not result almost entirely from accident, they are produced by a study which aims at something more than mere simplicity of plan. While the latter tends to make a large house seem smaller than it is, a certain degree of intricacy and complexity causes a moderate sized one to appear considerably larger, especially where the arrangement is such that rooms may present themselves unexpectedly after we suppose that we have gone over the whole. Still there are limits to be observed: complexity ought not to be carried to pe plexity; but some degree of the former greatly heightens every other merit.

V. It is odd; but now after the abuse thrown upon the poor National Gallery, because the rooms are no bigger than closets,—disgracefully confined and mean, some one starts up and assures us that they are utterly unfit for their purpose, because they are very much—*too large!* So at least says a writer in Blackwood's Magazine, who contends that spacious and extensive galleries, such as that of the Louvre are utterly unfit for showing pictures as they ought to be seen; and that the collection should be placed in small rooms,—not more than three or four paintings in each. This is surely running quite into the other extreme; but there certainly can be no doubt that as far as enjoying pictures themselves, and not the display of a parade of them, is the object, it is best obtained by hanging them so that each when looked at can be distinctly seen and examined, with nothing to distract attention from it.

VI. How people can reconcile themselves to windows without dressings in buildings where any degree of ornament or finish in other respects, is aimed at, is almost incomprehensible. Not even on the plea of economy has any one yet thought of entirely omitting capitals to columns, though it might be done with as much propriety and consistency; for if a window will answer all the necessary purposes of one, whether it be a mere aperture in the wall, or one properly defined and finished by its own architectural border,—so also will a column answer its purpose equally well, whether the top of it be fashioned as an ornamental member of it or not. Nor would it, though certainly more remarkable, be more solecistical and contrary to architectural principle to introduce columns without capitals among dressed windows, than naked windows among well dressed columns. Or if there be any thing to render the latter, and more common mode less preposterous than the other would be, it is because the columns themselves are generally quite superfluous, therefore were their decoration to be omitted, they might be dispensed with altogether. But then, on the other hand, so much the more absurd is it to have recourse to columns at all—at least for decoration,—under circumstances which forbid not only corresponding embellishment, but even ordinary finish in any other respect. Next to omitting window dressings entirely, is the fault of making them so poor and plain as to be hardly visible, as is the case in many of our modern Greek buildings, in which the dressings to the windows consist of a mere border distinguished by an insignificant moulding around it, so as to occasion equal sameness and insipidity.

The Great Western Steam-ship.—This noble vessel, the pride of Bristol and the queen of the ocean, was brought up the river on Saturday morning, 1st ult. and is now in Cumberland Basin, preparatory to her being placed in dock and undergoing various alterations, and for general examination and repair. During this week the public have had the privilege of viewing the interior of this splendid steam-ship on the payment of sixpence for each person, the receipts to be equally divided between the General H spital and the Infirmary. We understand tha nearly 2000!! persons paid to inspect the vessel on Monday, and many hundreds on each following day. This is the first time she has entered the dock gates since she left for London, to receive her splendid and powerful engines; her paddle wheels have been removed to enable her to enter the gates. Her approach to the basin at seven o'clock last Saturday morning was announced by the discharge of cannon, &c. The recept n she met with upon arriving (at the dock ga es) was very enthusiastic, arising from the loud and deafening shouts which emanated from the persons assembled "to do honour to her appearance." It is intended for her to resume the station she has so ably and successfully filled, on Saturday, the 15th of February, 1840, which will be the commencement of her twelfth voyage across the broad Atlantic.—*Railway Magazine.*

RAMBLES BY PHILOMUSÆUS.—No. IV.

LANDSCAPES ABROAD.

WHATEVER advantage foreign nations may derive by the education of the eye to beauty from the contemplation of objects of art, it is pretty certain that they will not easily surpass us in the scenes of nature. They may possess the same or finer outlines, they may bear the palm for correct drawing, but it is to us they must concede the chiar'oscuro, and what disputes with drawing itself the magic touch of colour. To carry out our artistical allegory, foreign landscape is of an Eginetan cast, severe and correct in its form, but destitute of that animation and finish which mark the later and more cultivated school. It is perhaps from the contemplation of our highly finished scenes, that our painters succeed in colour, and show such proficiency in landscape and cattle; that our poets excel in the descriptive; and that whatever is rural with us, is beautiful without coarseness or rusticity.

An Englishman passes from the tertiary scenes of our beautiful south, to the assimilated district in the neighbouring country of France, he can recognize the same smooth slopes, the same gently swelling knolls, the same richness of soil, and the same softness of character, but he finds a tameness, a want of animation and relief both in broad features and in details, which tell him at once that he is in another and a foreign country. He glides down the beautiful Seine and from St. Germain to below Rouen he perpetually finds a country spoiled from want of care, and a district of great capability wearing the face of a comparative desert. None of the bright fields of his native land, none of its varied and picturesque timber, no beautiful cattle spreading over the distant scene, he misses the hedge and the hedge-row, and above all he misses the dispersed population, the pretty seat or the lowly cot. Instead of these he finds no houses but in villages, little meadows and no variety of timber. From St. Germain to near Havre, there is nothing hardly to be seen but poplar, alder and willow, miles in length of distant forest, or long lines of well drilled poplars spreading along the roads or the divisions of estates. Now the maypole-like poplar is just the very last tree to be paraded thus in single file. The scenery has all the uniformity of foliage of American landscape, and there is only beauty enough to cause the traveller to regret that the whole does not show to equal advantage. On approaching Elbeuf, however, the scene changes, green meadows make up the foreground, the mottled cattle swarm among the pastures, oak and other dark trees, firs and the coniferous tribes, throw shade into the landscape, and the traveller as he looks at the tree-clad hills and grassy slopes is glad to find himself in a land of beauty.

In Flanders we find the same—long ranges of deformed limes and horse chesnuts making the straight roads more horrid, the brooks fringed with pollard willows, poplars like Cleopatra's needles running in lank rows as divisions of property, Scotch firs in patches to fertilize the land, and without meadows, water or cattle, one scene of stiffness and formality. The unhappy trees too are topped off into mopsticks so as to render horror more horrid.

The Dutch, however, if they have a poor country have a rich green sward, the weeping willow, and fine cattle; and an Englishman if he finds little to relieve, find no nakedness to distress the eye.

COMPARATIVE EFFECTS OF THE CORNISH AND LANCASHIRE SYSTEM OF WORKING STEAM ENGINES.

SIR,—As it is not now disputed by any one, that the Cornish or high-pressure expansive system of working the Boulton and Watt engine is more economical than that usually followed in the manufacturing districts, it may probably be interesting to a portion of your readers to have offered to their notice, an easy method of stating or comparing the duty or effects obtained by the two systems, for the purpose of shewing hereafter, the *amount* of saving that may really be expected by the adoption of the Cornish system; and also to have that saving expressed in terms that are generally understood and admitted by practical men.

The following cases are selected, because they have been recently laid before me for the purpose stated, by parties who are interested in having a careful examination of the subject, and who have also furnished me with the facts.

The engine from which the data for the Cornish system are taken, is that lately erected for the East London Water Works Company. The cylinder is 80 inches in diameter, stroke 10 feet, speed 10 strokes a minute, and doing a *duty* of 72 millions of pounds raised one foot high for one bushel, or 94 pounds of coal, the steam being cut off at two-fifths of the stroke. The area of the cylinder, of course, is 80 × 80 = 6,400 circular inches. The load on the piston is obtained by taking the counterweight which is 29 tons, or 64,960 pounds, and adding thereto half a pound per circular inch, or 3,200 pounds for the friction of the engine itself, making 68,160 pounds for the total gross load; which gives 10·65 pounds per circular inch, for the average pressure of the steam in the cylinder. The velocity of the piston being 10 × 10 = 100 feet a minute; the pounds raised one foot high per minute, will be 68,160 × 100 = 6,816,000, and the gross horse power exerted, is this number divided by 33,000, or 206·54 horses power.

The Lancashire system is illustrated by a pair of double acting sister engines working in a cotton factory in this country, and attached to the same crank shaft. Each engine has a cylinder of 40 inches diameter and 4 feet stroke, and makes 25 turns in a minute. The gross consumption of coal at the factory is 46 tons a week, the engine running 69 hours in that time. That portion of this consumption used for other purposes than working the engine, is usually estimated at 30 per cent., which includes that for steaming the factory, getting up the steam every morning, waste during meal times, &c. (particulars of which are given in the new edition of my work on steam boilers,) leaving about 32 tons or 71,680 pounds for the net consumption of the engines alone. The area of each cylinder is 40 × 40 = 1600 circular inches, the average pressure of the steam in the cylinder as taken by the indicator is 10 pounds per circular inch, and the whole load on the piston is 1600 × 10 = 16,000 pounds, which, of course includes the friction of the engine. The velocity of the piston is 4 × 2 × 25 = 200 feet a minute, therefore the pounds raised one foot high per minute, is 1,600 × 200 = 3,200,000; and the horse power exerted by each engine 96·96, or a total of 194 nearly.

COMPARATIVE DUTY.

	Lancashire.	Cornish.
a, Pounds raised one foot high per minute	6,400,000	6,816,000
b, Gross horse power exerted . .	194	206·5
c, Consumption of coal per week of 69 hours, in pounds . = d + 69	71,680	36,804·5
d, = c ÷ 69, ditto per hour = e + 60	1038·8	533·4
e, = d ÷ 60, ditto per min. = a ÷ f	17·31	8·89
f, = a ÷ e, Pounds raised one foot for each pound of coals = g ÷ 94	369,728	765,957
g = f + 94 Pounds raised one foot high for 94 of coals . .	34,754,132	72,000,000
d ÷ b, Pounds of coal consumed per hour, for each horse power .	5·35	2·58

The letters in the above table indicate the mode of calculation, and it will be perceived that the results in the second column (except the two first lines and the two last,) are obtained by reckoning from the bottom of the column upwards. It must be borne in mind that the horse power exerted by the factory engines as stated above, includes that required to turn the whole of the shafting, about one-third of the whole, which reduces the *net* effective power expended in turning the machinery to $(194 - \frac{191}{3}) = 129\frac{1}{3}$ horses nearly, or $64\frac{2}{3}$ horse power for each engine, and making the consumption of coal equal to half as much more as before, or $(5{\cdot}35 + \frac{5{\cdot}35}{2}) = 8{\cdot}02$ pounds per horse per hour. What the net effective power of the Cornish engine is, of course, cannot be ascertained without measuring the water delivered, but it is not at all necessary for the purpose of this comparison.

Should the above be considered a fair method of stating the subject, and it is respectfully submitted to the correction of the advocates of either system, I shall be glad, with your permission, to go into the question of the *causes* concerned in producing the great difference observable in favour of the Cornish system, and also the comparative cost or expenditure of fixed capital for the two kinds of engines when doing an equal quantity of work, with a view to test the propriety of adopting the Cornish system in cotton factories.

I am, sir, yours, &c.

R. ARMSTRONG.

Manchester, Dec. 1839.

CURTIS'S PATENT RAILWAY IMPROVEMENTS.

RAILWAY TRUCK.

Fig. 1.—Side elevation.

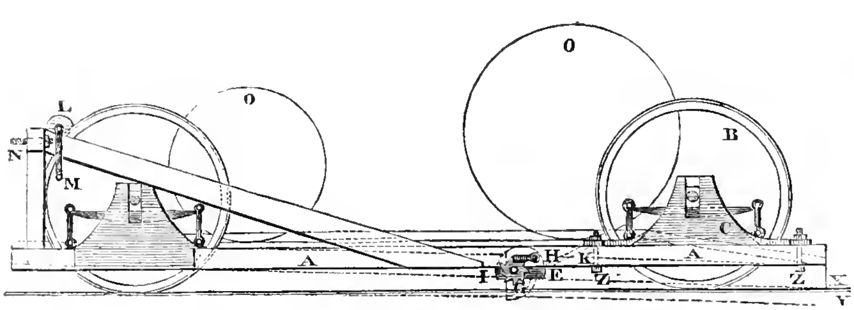


Fig 2.—End elevation.

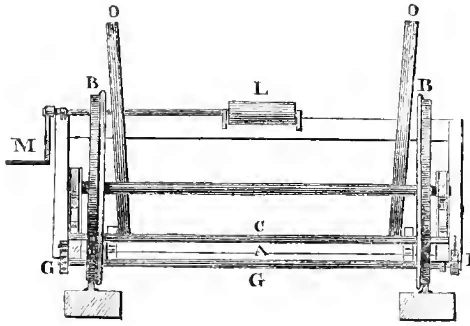

Fig. 3.—Plan.

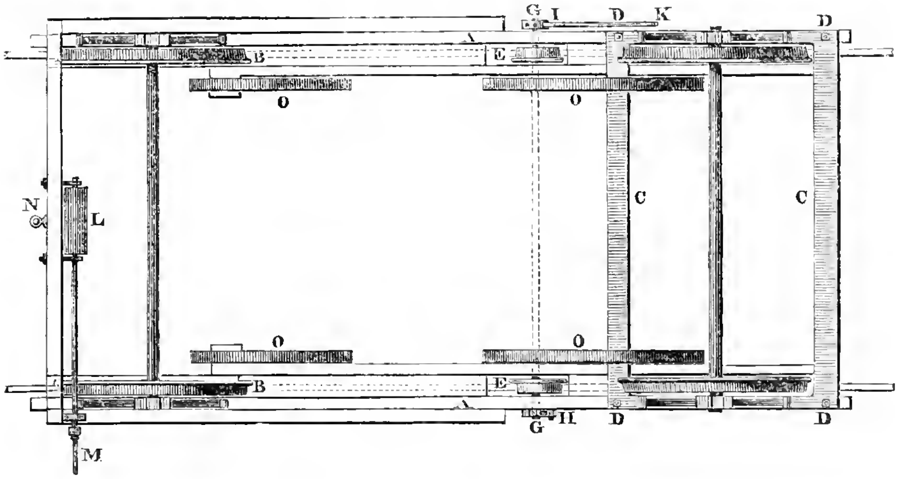


DESCRIPTION.

Figure 1 is a side view, figure 2 an end view, and figure 3 a plan of the machine, the same letters refer to the same parts of the machine in each figure, so far as the parts are thown in each. A is the framing of the machine, which is suspended below the axle in the usual way, B the hind wheels connected with the shifting frame C, which frame is held in its place by the bolts DDDD, or by any other usual and suitable means. EE are two eccentrics hung upon the cross shaft F, upon one end of which shaft the ratchet G is hung, and upon the other the head I, into the holes of which the lever K is inserted, when it is required to turn the shaft F round, so as to bring the eccentrics into contact with the rails or otherwise. L is a windlass placed upon the front bar of the machine round which a rope coils, so that when a carriage is required to be placed upon the machine, one end of the rope is made fast the carriage, and the other end to the windlass, then a man turning the windlass round by means of the handle M, the carriage is drawn upon the machine; the machine is connected to the train by means of the coupling N in the usual way, and the diagonal bars are placed as shown, in order that the concussion of the train may be transferred to the main frame of the machine A. OOOO are the wheels of a carriage placed upon the machine, the body and carriage is omitted in the drawing, as it is not material to the explanation of the invention that they should be shown.

The mode of operation is as follows:—when a carriage is required to be placed upon the machine, the eccentrics are brought upon the the rails and made to occupy the position shown by the red lines in figure 1, the effect of which is to raise the end of the carriage to which the shifting frame and wheels are attached, a space equal to that included between the shaded line X and the red line Y, and to support it whilst the frame C and wheels B are withdrawn, then the eccentrics are turned back until they occupy the position shown in the drawing, when the end of the machine is lowered to the ground and occupies the position shown by the blue lines ZZ. The carriage is then brought to the machine, the rope from the windlass is made fast to it, the floor of the machine being formed into an inclined plane, the carriage is dragged upon the machine by the windlass with great facility, when placed upon the machine the eccentrics are again brought into the positions shown by the red lines, which raises the end of the machine, the shifting frame C and wheels B are connected with the machine, and made fast by the bolts D, the eccentrics are then brought into the position shown in the drawing, riding clear of the rails; the ratchet G and paul H are provided to retain the eccentrics in any position they may be placed in, the best way to effect all these operations is to place the machine upon a turn table, the fore wheels and the eccentrics being upon the table when the machine can be disengaged from the wheels and placed to receive the carriage in a very simple and easy manner, the same operations apply if the machine is employed for goods or cattle, or any other purpose.

REMARKS ON RAILWAYS,

WITH REFERENCE TO THE POWER, &c. EMPLOYED UPON THEM.

SIR—This subject has occupied my attention for some time past, but I have been more particularly led to address you by seeing the description of Mr. Curtis's endless rope apparatus in the last number of the Journal.

It has often been a subject of surprize to me, that so few attempts have been made to limit the enormous outlay of money in forming modern railways. When almost every branch of mechanics, manufactures and the arts are receiving the attention of scientific men, and when patentees without number are enabling us to do that for sixpence which used to cost us a shilling, ought we to be satisfied with expending all our ingenuity in examining the relative merits of brass and copper tubes, or in ascertaining the best form for rails and chairs, I think not: and though Messrs. Stephenson, who are unquestionably the first railway engineers, may tell us, that without locomotive engines, railways would be nothing, and though by this craft they have their wealth, yet nothing daunted, I will give you my ideas on the subject. We will suppose, for example sake, a railway is to be constructed from one town to another, say from Sheffield to Manchester, where the country is so hilly as to require a summit of upwards of 900 feet, and a tunnel 3 miles long, where the inequalities of the ground are such as to require embankments and cuttings in some places of 90 or 100 feet, and in many of 40 or 50, in order to make it at all suitable for locomotive engines to travel upon. We all of us know, that under ordinary circumstances, 50 feet per mile require the engines to be nearly three times as powerful as those which would be required upon a level, consequently, three times the weight of coke and fuel, as well as a great addition to the weight of the engine and tender, therefore, it becomes a question of some importance to ascertain whether a cheaper power cannot be adopted than locomotive engines. About ten years ago, Messrs. Walker and Rastric gave it as their opinion, that Mr. Thompson's plan of reciprocating ropes would be found more economical for the Liverpool and Manchester railway than locomotive engines. And be it remembered, this railway is uncommonly favourable for locomotives, compared with nearly all the others in England, with the exception of the two inclines. The only advantage gained by locomotive engines over the stationary system, since their report, is economy in the consumption of fuel, by having tubes instead of a large flue, and though this is a very great improvement, how is it that with a consumption of fuel not one-fourth of what was anticipated, we are told they cannot afford to take goods so as to leave a reasonable profit. The only solution to this problem is, that the expense incurred in levelling and forming railways, so as to make them fit for locomotive engines, together with the original cost, wear, and tear of locomotive engines, tenders, and rails, is such as to demand a larger toll upon the goods than can be afforded. Not to weary your readers by going into calculations, I will assert that the plan of endless ropes will be found in the case of the Sheffield and Manchester railway, or any other railway, with one continued rise to the summit of 35 feet rise to the mile, to be far more economical and efficient than locomotive engines. If we reject locomotive engines, the face of the country will not want excavating or embanking, excepting in a very few cases, which will save probably one-half of the original outlay, viz. £400,000., and the interest of this at 5 per cent., which is £20,000. per annum, will be saved to the shareholders; other things being the same, and that other things are as favourable must be our next business to prove. Any person acquainted with the country in question, will admit that reservoirs may be formed and water collected to almost any quantity, (of course without injury to the mill owners,) at or near the level of the summit, for a trifling expense, which will furnish us with sufficient power without having recourse to locomotive engines. We will pass over the intermediate steps of engine-houses, water-wheels, &c. from an anxiety to keep these remarks within reasonable limits, and not from an inability to go into them. The principal objections to the reciprocating plan, or any other plan with ropes I have seen, are that the trains must all arrive together, stop at the stations to be hooked on and off, and in some of them cross over to the other rails. We will not dwell upon these objections, but provide the remedy, which is to divide the line into lengths of one mile each, and to have a station at the end of each mile, these will be divided into two kinds, the first contain the engine, water-wheel, or whatever the power may be, and are placed every other mile; we will call them No. 1, 2, &c. The second stations are, where the two drums, or large pulley wheels are placed, and occur every other mile, being placed halfway between the first mentioned, we will call these A, B, &c. From one of these stations to the other, extends an endless rope of two miles long, or one mile from wheel to wheel; one end passing round one of the wheels at the numerical stations, and the other round one of the wheels at the alphabetical, there being two wheels at each station, capable of working in concert, by means of which two endless ropes can be worked by one engine in both directions. It is not intended to work more than one at once by one engine, but only to give a signal to the man at the station No. 2, that he must set the engine or water-wheel going, and at the same time it is intended to couple them so as to ensure a uniformity of speed between the two ropes, before the train changes from one to the other, therefore one engine will be working at each end for a short time, there being two endless ropes coupled together working between them. This system of signals to be observed throughout the line; the object of it is to prevent any jerking or breaking of ropes, &c., as there are no stoppages at the stations, the first endless rope being liberated and the second taken when the train is at full speed. The way this is done is by a long iron bar fixed obliquely in the ground near the rope, nearly in the same direction, and as the first carriage passes over this bar, one side of the claws or holders of the rope, slides along the bar and is forced open, which liberates the rope; the impetus of the train carries it forward to the rope at the second station, (twenty or thirty yards would be sufficient,) where another bar fixed in a manner similar to the bar already described, again opens the claws, and a fork likewise fixed in the ground under the rope by the same operation, throws the rope between the claws, they close upon the rope and the train proceeds. The relative distance of claws, bars and rails being always the same, this part of the machinery can never get out of order, nor require any superintendance.

To elucidate the system proposed still farther, we will suppose a train is about to leave one end, when none of the ropes are in motion, it is first brought along the railway a little in advance of the station No. 1, then a pair of claws fixed on the first carriage, (which open by a lever and close by a strong spring,) grasp the rope, but without injuring it. The water-wheel or engine is then put in motion, and along with it the drum or pulley-wheel, endless rope, and consequently the train. The speed is got up to the maximum, and thus it proceeds till it arrives within 200 yards of the station A, being the first half-way station. The man at this station by a conical coupling, spring coupling, or in any other manner, which will gradually effect the same, connects the pulley-wheel of the first endless rope, or the one already described with the pulley-wheel of the second endless rope. The second endless rope is set in motion, and by this signal, viz. the moving of the rope, the man at the station No. 2, puts on the power, and before the train has got to the second rope, the speed of the rope is the same as that of the train. As soon as the man at the station No. 1 judges the train has left the first rope, he takes off the water or steam, and the first endless rope leaves off running. It is not needful to describe the trains' progress forward, for the same thing occurs at every change. It is evident from the foregoing description, that the going train always keeps to one side, and the coming train to the other, and as the rope is the propelling power, or means of power, one carriage can never overtake another. A carriage to be taken up at any place on the line, may either be done in the manner described by your correspondent, or by an incline, to set the carriage in motion long enough to get up its speed before it is fixed to the train. In conclusion, I will make a few general remarks; upon considering the subject, two important facts force themselves into view;—the first, that almost any number of undulations may occur in the line of the railway, provided there be no convex curves in the section of the ground in the space of one mile, (concave curves would not signify, for they would diminish the friction of the rope rather than add to it.) The second is, let the country be as mountainous as the Simplon, railways may with advantage be made over it, provided there be a considerable traffic. The first of these will enable us to make railways at one-half the cost of the present system, the other to choose our own ground, and not be obliged to go in a particular direction or level, to suit locomotive engines, leaving large towns entirely out of view.

Here we can have a railway at one-half the expense of the other, at one-half the wear of rails, have no collisions between trains, and at no greater annual expense, but we won't have it;—and why? because if such a thing were attempted, Demetrius and the craftsmen, (and they are a very powerful body,) would run about the share-market and shout with a loud voice, "great is Diana of the Ephesians," and all the directors and shareholders in the railways already made, would stifle all argument with the cry of "great is Diana of the Ephesians," and at last, like poor silly sheep going to the slaughter, the projectors of and subscribers to contemplated railways, would join in the cry, and louder and fiercer than any shout "great is Diana of the Ephesians—great is Diana of the Ephesians."

Sheffield. DIOGENES.

(To be continued.)

PROFESSIONS IN FRANCE.

"They do these things better in France," has been echoed by Sterne's Starlings almost for the last century, and that we may enable our readers to pick out what good they can, and eschew the evil, we have thrown together some notes, based upon official documents and upon the almanacks and directories. With regard to the directory, by the bye, it comes from the hand of an editor with many tails, and is dated in the 32d year of the publication, and in the 10th year of our reign, or as it phrased *Xe de la continuation par l'Editeur actuel* (*Editeur*, usually means publisher.)

We shall throw our notes together just as they come, and leave their connexion to the industry of our readers. One of the first things that strikes us, is a dealer in essence of mahogany *(essence d'acajou,)* though what that is, we do not know. The list of country architects is, to a great degree, filled up with surveyors, as they are there called *geometres du cadastre*. Among the cement dealers we find Impermeable Mastic Powder of the Romans, Stone-coloured Mastic, Adialyte Roman Cement, Lucidonic Colour, Economic Bituminous Painting, (we presume tarring fences,) Hydrofugic Mortar, Hydrophyluctic Mortar, &c. One brick-maker has an establishment for making moveable terra cotta letters for shop boards; the master carpenters are formed into a body by a police ordonnance of the 9th December, 1808, for internal government, for inspecting the solidity of buildings, and for preventing pieces of carpentry from being placed so as to cause fires. Their tools must be stamped with a punch bearing their family name at full length; no journeyman must work on his own account beyond two days, without a previous declaration at the Prefectore of Police. Oh, blessed state of affairs! when shall we have the advantage of protection from the authorities of Scotland-yard, and be under the enlightened directors of the nearest station-house. The masons and locksmiths enjoy the same privileges; the paviors also, by a police ordonnance, are prohibited from undertaking any work without being inscribed at the Prefectore, and having their tools stamped with their names.

The number of well borers is ten; designers of bronzes, carpets and ornaments, ten; designers of paper hanging, twenty. There are several offices for doing specifications, drawings, measorements, estimates, &c. The gas fitters are twelve. Of engravers, there are in mezzotinto nearly a hundred; architectural, twenty; topographical, thirty; in wood, twenty; for paper hangings, ten; of lithographers, fifty. The engineers are all government functionaries, dispersed over the provinces, except about thirty civil and practical engineers at Paris. The steam-engine makers are six-and-twenty; the modellers, eleven; moulders of effigies, fifteen; mosaic factories, five; scene painters, seventeen; decorative painters, fifteen; painters of artificial marbles and woods, thirty; glass and enamel painters and gilders, thirteen; platina manufacturers, twelve. The surveyors are about two hundred and fifty in number.

The next portion of our subject, will be the immense mass of government functionaries, one of the best tests of professional independence, whatever it may be of national encouragement. The first that comes in our way is the royal household, direction of crown buildings, with thirty-three architects of all grades. The next is the private domain of the king, with another board of architects. We then have the home department, directors of public buildings and monuments, with twenty-one employers of the general board, and a hundred and five district functionaries employed in different public works. The Prefecture of the Seine, almost equally prolific, has about a hundred and fifty. The Prefecture of Police has also a number of good births—the division of architecture alone, sixteen.

The engineers come off as well. In the war department, they are, of course, well provided for; but the ministry of public works, is their great support, there are to be found the names of fifty. In the Prefecture of the Seine, about as many.

COMPETITION DESIGNS.

Sir—You will perhaps favour me by inserting the following in an early number of your useful Journal.

Derby, Your's respectfully,
13*th Dec*., 1839. B.

Two advertisements for designs have appeared in the "Times" this month, one for laying out 25 acres of ground near Ipswich, for which premiums of 30*l*., 20*l*., and 10*l*. were liberally (?) offered; the designs to be sent in by the 30th of this month! The other design required was for the Lincoln Diocesan School, to accommodate 200 boys; with a master's house attached, to have accommodation for 40 boarders, which was to be furnished by the 17th of this month (!) the board to assemble on the 18th, to make their selection (!!!) A short time since, designs were requested for a gaol at Peterborough, which were to be sent in by *twelve o'clock* of the 30th November, *when* the magistrates would meet to select the design! These last two cases, if the designs were really selected at the time announced, form a beautiful contrast to the dilatoriness of which Mr. Dionysius complains in the Sunderland Athenæum committee. The gentleman, Mr. Billington, whose design is adopted by that body, is an architect, surveyor, and civil engineer, as well as joiner and builder, in Wakefield.

It may be satisfactory to the "young architect" to know that tenders for the works were advertised for certainly three months since, as he may ascertain by refereuce to the "Leeds Mercury" of about that date.

The exertions of the Manchester Architectural Society are entitled to great praise from the profession. It is their intention, with the concurrence of the competing architects, to exhibit the designs for the Lancashire Independent College, which were advertised to be sent in by the 19th of October last. The building to cost £12,000.

Of the favourable result of such exhibitions, I am very sanguine—as they will awaken an interest in, and a taste for architecture among people in general; besides acting as a check upon the judges in competition.

But what are the Institute and the London Society doing? It is now three years since the first part of the first volume of the "Transactions of the Institute" appeared. Are we to have no more? The non-appearance of part the second does not speak *volumes* in favour of the interest of the communications that the Institute has received: unless, indeed, the publication of the Transactions was a failure. As to the Society, as far as we provincials are concerned, it is perfectly barren. Why do not *they* follow the example of the Institute, and throw open *their* competitions to the profession at large?

I consider that the Institute might exert itself very beneficially on behalf of the profession, by interfering in competitions.

I suggest that a sub-committee be appointed, which might be called the Competition Committee, whose business it would be, when designs are advertised for, to direct the Secretary to obtain particulars; and should they consider the time allowed too brief, or the premium too small, to urge upon the parties advertising the desirableness of increasing either. By thus bringing the matter home to the different bodies, I apprehend that the profession would be generally thought more respectable. The exertions of such a body, would be more likely to succeed than the isolated efforts of individuals.

To parties about to advertise, if requested, the Committee might furnish many useful hints. In addition to this, they might have exhibitions of the designs in remarkable competitions, and thus obtain some increase to the Institutes' income.

If, following the example of the Useful Knowledge Society, they would appoint local committees throughout the country, they would have their trouble lessened, and would unite the profession more intimately than it is, These committees, it is evident, may collect much useful information; as every provincial architect is not *personally* acquainted with these metropolitans, It should not, I think, be considered essential that the local committee be members of the Institute, but provincial architects, of whose professional standing the council was satisfied, might be requested to act. Though these suggestions may not meet with approbation, I must regret that neither the Institute, nor the Society, have opened an exhibition of the Royal Exchange designs. The gods will not help them who will not help themselves, neither will the world assist an apathetic profession.

It is to hoped that the Liverpool Society will exert themselves to obtain an exhibition of the Assize Courts designs; though the non-exhibition of the designs for the St. George's Hall argues a great deal of inactivity or apathy on their part.

That competition seems to have reached a satisfactory conclusion, For, though some may think that a better design might kave been selected, nobody will question the honourable conduct of the "Liverpool gentlemen."

B.

COMPARATIVE POWER OF STEAM ENGINES.

The following calculation by Mr. Wicksteed, the engineer of the East London Water Works, exhibiting the saving of fuel to be effected by using a single acting expansive engine and an overshot water-wheel, instead of a double-acting condensing engine of the ordinary kind will be found interesting. This was made at the request of His Excellency Edhem Bey, ambassador from the court of Egypt, upon his late visit to this country.

A double-acting low-pressure engine of the ordinary construction of 50 horses power for spinning cotton, will consume from 10 to 15 lbs. of coal per horse power per hour, say on an average 12 lb. This is, however, a low estimate for Lancashire, where the consumption is generally much greater, coal being there less expensive than in several other parts of England. If we allow 311 working days per annum of 12 hours each, we shall have the total consumption of the above engine for one year = 50 × 12 × 12 × 311 = 2,239,200 lb. = 999 tons, 12 cwt. 3 qrs. 12 lbs., say 1000 tons at 50s * = £2500.

A single-acting expansive engine on the Cornish plan of 50 horses power, if used for raising water to turn an overshot water-wheel, will not produce a power of 50 horses available for working the cotton machinery, since the effect of the water, when applied as a motive power, through the medium of the overshot water-wheel, will not exceed 66 per cent. of the power required to raise the water. Now 66 : 100 : : 50 : 76 = the number of horses power of the engine which will produce the same mechanical effect by this plan as by the usual mode.

A Cornish engine of 76 horses power will consume from 2 to 2½ lbs. of coal per horse power per hour, say 2½ lbs.; thus the consumption for one year will be equal to 76 × 2·5 × 12 × 311 = 709,080 lbs. = 316 tons 11 cwt., say 317 tons at 50s. = £792 10s.

COMPARISON.

The cost of coal per annum by the common mode is	£2500	0	0
Ditto by the proposed mode . .	792	10	0
Saving per annum = 68 =	£1707	10	0

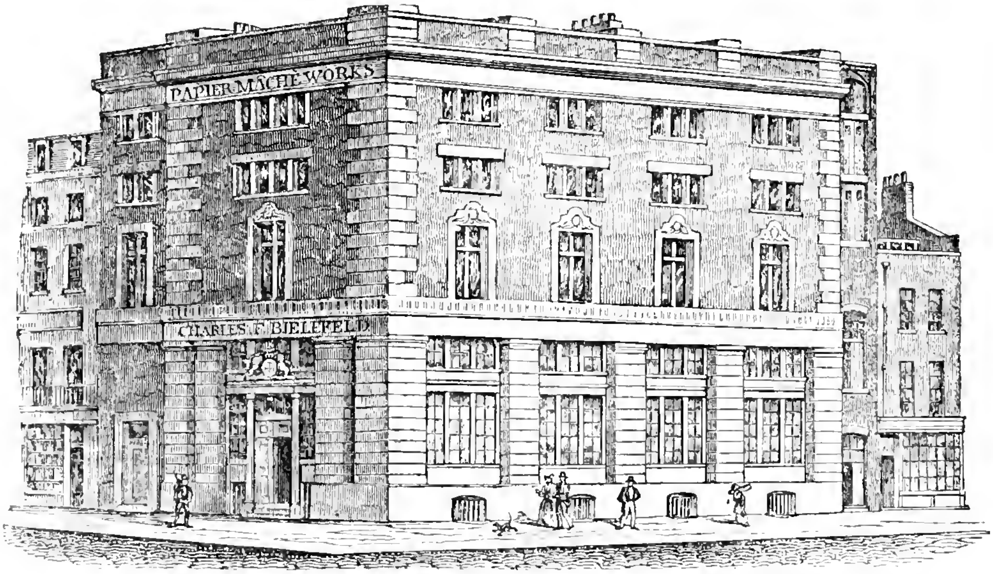
† This is the price of coal in Egypt.

The irregularity of the action of the steam in ordinary low-pressure engines is very nearly counteracted by the use of a fly-wheel; nevertheless, in some of the cotton factories, (for instance, that of Messrs. Lane, of Stockport) two engines are employed to work the same machinery, the cranks being fixed at right angles to each other, as in marine engines. Shis arrangement equalizes the action of the steam still more, yet the motion is not so regular as that of an overshot water-wheel, where the supply of water is uniform, as it would be in this case, the speed of the engine being regulated by the use of the cataract, to any given number of strokes per minute, and the delivery of water consequently uniform.

It should be observed that no large quantity of water will be required, as the same water may be used over and over again with very little loss.

When this calculation was made, very little practical knowledge of the consumption of coals for a Cornish engine in London had been obtained, and although we have never disputed the reports from Cornwall, yet many engineers of great experience had doubted the correctness of the accounts from Cornwall; it has now, however, been proved that the great engine lately erected by the East London Water Works Company at Old Ford, does not consume upon an average more than $2\frac{6}{10}$ lbs. of coals per hour per horse power, and as the coals used are the refuse of Newcastle coals, the largest piece not being greater than ⅜ inch in diameter, we can have no doubt that Mr. Wicksteed's estimate of 2½ lbs. of coals per hour per horse power of *large* coals may be safely relied upon.

BIELEFELD'S PAPIER MACHÉ WORKS.



BIELEFELD'S PAPIER MACHÉ WORKS.

A no less singular than conspicuous object, the building lately erected in Wellington Street, North, can hardly fail to attract notice, yet at the same time is likely to puzzle the architectural critic. It has already been spoken of both in the Companion to the Almanac, and in an article on London Shops and Gin Palaces, in the December Number of Fraser's Magazine; nor do we see reason to dissent greatly from the opinions there expressed. The defects of the design is that there is very little sort of agreement between the upper and the lower portion of the building, either as to style, character or material. While the latter is exceedingly plain and sober, the other is fanciful—not to say freakish in the dressings given to the first floor windows, which, nevertheless, do not possess the degree of richness, which would reconcile the eye to what, it must be acknowledged, is *outré* in manner, and which therefore required to be treated not with coldness, nor even sobriety.

We do not object to an intermixture of stone and red brick; on the contrary, we are of opinion that it might frequently be rendered productive of considerable effect; but then we should like to see the two materials combined throughout, from the ground upwards, and not, as is here the case, have a building look as if begun and carried up to a certain height in stone-work, and then completed in brick with only stone dressings. Again, the piers below look narrow and weak compared with those between the windows of the first floor;—a fault that might have been obviated by arching the openings between them, and making the entresol windows in the heads of the arches. This would also have diminished the formality now occasioned by the numerous horizontal lines of those windows and openings, and unnecessarily increased by those of the horizontal rustic joints.

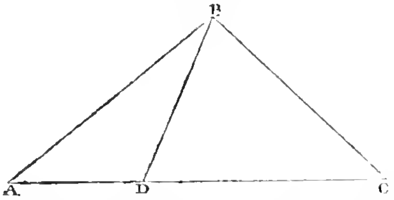
In one respect, indeed, the whole possesses a certain merit, because there is hardly a possibility of mistaking what the building is intended for. Its aspect at once announces it to consist not only of a shop below but a manufactory in the upper stories. It likewise contains spacious show-rooms, relative to which and their contents we shall probably be able ere long to give a more detailed account. The building stands at the corner of Wellington and Exeter Streets, the narrower front or end, being towards the former, the longer one towards the latter; but in regard to this some liberty has been taken in the cut, for though the whole of the South side of the building is shown, not more than the first two windows from the corner of Wellington Street would be visible in the direction here chosen, owing to the narrowness of the other street.

ON THE TESTING OF SURVEYS BY CALCULATING THE LINES OF CONSTRUCTION.

By S. Hughes, C.E.

In transferring to paper the measured lines of a large survey, it is always considered by the surveyor a matter of great satisfaction if the lines prove or fit in to each other as it is called.

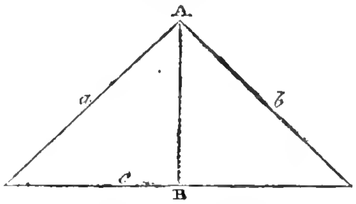
That the meaning of this term may be understood by those who are not conversant with the practice of surveying, suppose three lines have been measured in the form of a triangle, A, B, C, and a fourth line B, D has been measured from one of the angular points to D in the opposite side. It is evident that the three sides of the triangle being given, the length of B D is determined, and ought on the ground to measure neither more nor less than the distance in a direct line from B to D.



Now, if on laying down the above diagram on paper it be found that the distance between B and D either exceeds, or is less than that measured on the ground, the presumption is that an error has been committed, and the work should forthwith be examined in order to discover it. B D is called a proof line, and the above example is given to illustrate the nature of these lines.

The object of this paper is to investigate a few simple formulæ for determining the lengths of proof lines by calculation, in order to save the trouble of laying down at an inconvenient time the main lines of extensive surveys, and to guard against the danger of error in laying down the lines on paper.

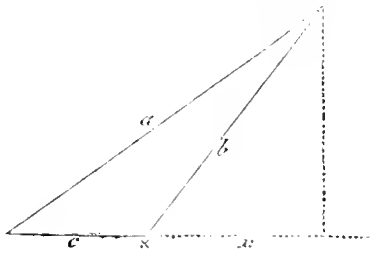
Prob. 1st.—Let a, b, c, be the three given sides of a triangle, it is required to determine the perpendicular A B from the vertex to the opposite side c, and also the segments into which the side is divided



by such perpendicular. Put $x=$ one of the segments, and we have $a^2-x^2=b^2-(c-x)^2$ or $a^2-x^2=b^2-c^2-x^2+2\,c\,x$ add x^2, and $a^2=b^2-c^2+2\,c\,x$; subtract b^2-c^2 and $a^2-b^2+c^2=2\,c\,x$. Divide by $2\,c$ and $\frac{a^2-b^2+c^2}{2\,c}=x$ or $\frac{a^2-b^2}{2\,c}+\frac{c}{2}=x$ the greater segment.

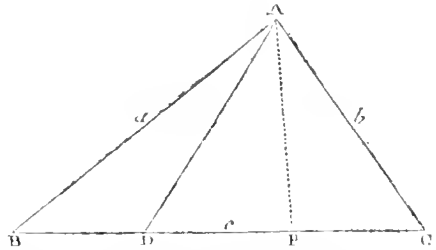
Now the difference of two squares is equal to the product of the sum and difference of their roots. Let s and d be the sum and difference of the two sides a and b, then $\frac{c}{2}-\frac{s\,d}{2\,c}=x$ the greater or less segment, according as the positive or negative sign is used in the formula. The perpendicular A B of course will be $\sqrt{a^2-x^2}$. From the nature of similar triangles it is also$=\frac{x\,a}{b}$ where x is the lesser segment, and $=\frac{x\,b}{a}$ where x is the greater segment.

Suppose an obtuse angled triangle, then $a^2-(c+x)^2=b^2-x^2$ or a^2-



$c^2-x^2-2\,c\,x=b^2-x^2$. Add x^2 and $a^2-c^2-2\,c\,x=b^2$. Add $2\,c\,x$ and $a^2-c^2=b^2+2\,c\,x$. Subtract b^2 and divide by $2\,c$, then $\frac{a^2-b^2}{2\,c}-\frac{c}{2}=x$, or substituting as before the sum and difference of a and b we have $\frac{s\,d}{2\,c}-\frac{c}{2}=x$, and the perpendicular here will be $\sqrt{b^2-x^2}$.

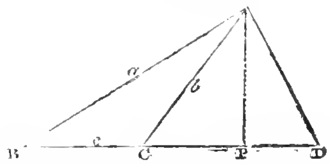
Application I.—Given the three sides $a\;b\;c$ of an acute angled



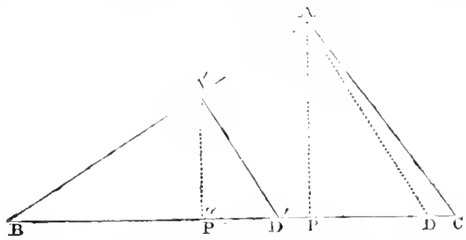
triangle, also B D, and consequently D C the segments of the base c, required the length of the proof line A D.

Put B D$=d$ the perpendicular A P as found by the preceding problem$=p$, and, the segment B P also found by the problem$=s$, then $\sqrt{p^2+(s-d)^2}=$A D.

Case II.—Let the triangle be obtuse as A B C, then retaining the same letters as above $\sqrt{p^2+(d-s)^2}=$A D.



Case III.—In the triangle A B C, the three sides are given, also the distances B A′, B D′ required the length of the proof line A′D′.

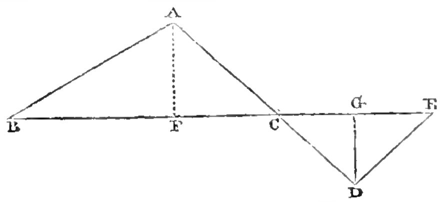


Through the point A draw A D parallel to a A′ D′, then B A′ : B A : : B D′ : B D and A D may be found as shewn in case I. Then we have B A : B A′ : : A D : A′ D′ the length required.

Or suppose the two sides B A, and B C are given also B A′, B D′ and A′ D′ and the length of the proof line A C be required. Through A′ and A draw A′P′, and A P perpendicular to B C and find the length of A′ P′ by the problem. Then B A′ : B A : : A′ P′ : A P find also the length B P, and then $\sqrt{\text{A P}^2+(\text{B C}-\text{B P})^2}=$A C.

Corollary. By means of the formula in this case may be determined also any proof line measured on the opposite side of the base line to that on which the triangle has been constructed.

Thus let A B C be the triangle of which the sides are given, and of



which one of them A C has been continued to D, and its extremity connected by the line D E, with another of the sides B C also produced to E. Draw A F and G D perpendicular to B E, and find the length of A F by the problem, then A C : C D : : A F : D G. The distance C G will then be$=\sqrt{\text{C D}^2-\text{D G}^2}$. And E D$=\sqrt{\text{G D}^2+(\text{B E}-\text{B G})^2}$

ON THE SUPPLY OF WATER TO THE METROPOLIS.

Observations on the past and present supply of Water to the Metropolis. By Thomas Wicksteed, *Civil Engineer. Read before the Society of Arts, May 24, 1835.*

[This paper which we now present our readers was originally published in the Transactions of the Society of Arts; as we consider its merits entitle it to a more extended circulation, we thought that we could not do a better service to its author and the public, than to take this opportunity of calling attention to it.]

I take the liberty of prefacing the observations I am about to make upon the past and present supply of water to the Metropolis, by stating that it was at the repeated request of my valued friend Mr. Aikin that I was induced to think of attempting to amuse the Society for an hour: and, should I be unsuccessful in the endeavour, I trust credit will be given me for trying, at least, to make a return, however trifling, for the pleasure and instruction I have derived from this Society during the last twelve years.

It will be my object to show the great advantages the inhabitants of this Metropolis derive from the abundant supply of good water which they now have, in comparison with the scanty supply in ancient times.

Supply previous to A.D. *1236, by Running Brooks.*

The inhabitants of London and its suburbs previously to the year 1236, in the reign of Henry III., were supplied with water not only by the Thames, but also by the following streams, namely, the River of Wells, Old-bourne or Hill-bourne, Wall-brook, and Lang-bourne.

The River of Wells, so called from its being formed by the united streams from several wells in the neighbourhood of the Charter House and Smithfield, flowed to Holborn Bridge. The Old-bourne, or Hill-bourne, so called from its running down a hill, rose near Holborn Bars, and running west, joined the River of Wells at Holborn Bridge: from thence the united streams flowed between the Fleet and Bridewell into the Thames near Blackfriars Bridge. In 1307, at a Parliament held at Carlisle the 35th of Edward I., Henry Lacy, Earl of Lincoln, complained that whereas formerly the watercourse under the Fleet and Holborn Bridges was sufficiently deep and wide to allow ten or twelve ships at once, loaded with merchandize, to come up to Holborn Bridge, but that in 1199, in the first year of his reign, King John had granted to the Knights Templars ground to erect a mill upon, at Castle Baynard, and the whole of the water in this watercourse (which was afterwards called Turn Mill Brook) to work it; owing to which diversion chiefly, and also to the filth of the Tanners choking it up, and divers other impediments, vessels could not now enter as they were wont; he therefore prayed that the mayor and sheriffs of London might be directed to view the watercourse to substantiate his statements. It was in consequence cleansed, but was never again of the depth or breadth that it had formerly been. In 1502, the 17th of Henry VII., the whole course of Fleet Dyke, then so called, was effectually cleansed so as to allow boats with fish and fuel to navigate as far as Holborn Bridge.

In 1589, in the 31st of Elizabeth's reign, the Common Council of the city granted a fifteenth for the cleansing of this brook, or dyke, and for this purpose the springs on Hampstead Heath were collected into one head and conveyed by means of a channel to Fleet Ditch, to scour it out; but after spending a large sum of money, the work proved a failure, and the banks falling in, the Ditch was choked up more than ever.

In 1668, in Charles the Second's reign, after the fire of London, it was again cleansed, and a handsome canal was made with brick walls and wharfs on each side as far as Holborn Bridge, 2100 feet long, 40 feet wide, and 5 feet deep at a middling tide; but the expense of making this canal, wharfs, &c., (amounting to nearly £28,000,) and the annual cost of keeping it free from mud was so great, that in 1733 the citizens obtained powers from Parliament to fill up the ditch between Fleet Street and Holborn, and to build a market thereon, the act providing that two spacious arches, of 10 feet high and 6 feet wide, should be made and maintained as common sewers, to carry off the waters of the rivulets and sewers that used to fall into the ditch; and in 1760, in George the Third's reign, when Blackfriars Bridge was built, the remaining part of the Fleet Ditch, from Fleet Street to the Thames, was filled in, and the sewer was extended.

It would appear that Fleet Ditch was the channel into which the River of Wells, from the east, and the Old (or Hill) Bourne from the west, flowed, and that the tide flowing up to Holborn Bridge made it navigable so far. That at one time it was called the River of Wells because that was the largest rivulet that ran into it; afterwards Turn Mill Brook, when it was rendered unnavigable by the erection of the Knights Templars' Mill, and the consequent diversion of its waters; afterwards, when the mills were removed, and it was cleansed again and rendered navigable, Fleet Dyke, so called because it was a watercourse allowing many vessels or a *flet* to pass up;—and afterwards Fleet Ditch, when the unsuccessful attempt to scour it, by means of a channel (which channel is now also called Fleet Ditch,) from the Hampstead springs, had been made. The Old (or Hill) Bourne is now covered over.

Wall-brook derived its name from the circumstance of its being the only running brook that passed through the City walls.

It entered the City near to the east end of Beth'lem Hospital, between Bishopsgate and Moorgate, passed on to Lothbury, under St. Mildred's church, Bucklersbury, Wallbrook Street, and Dowgate Hill into the Thames. It is said to have been in ancient times navigable as far as Bucklersbury. It is now arched over, and houses are built over it in many places.

Langbourne-water was a long and great stream of water breaking out of the ground at the east end of Fenchurch Street, and running directly west, nearly to the end of Lombard Street, turned to the south and divided into several rivulets, some falling into the Wall-brook, and others running in separate streams to the Thames at Dowgate; the division, or *sharing*, of the stream gave the name to Sharebourne (or Sherbourne) Lane.

A watercourse intersected the Strand at Salisbury Street, and another near Somerset House.

Supply previous to A.D. *1236 by Springs.*

Besides these running streams there were a great many wells and pools, namely, Holywell, in Shoreditch; Clement's Well, in St. Clement's Inn in the Strand; Clerks' Well, near Clerkenwell Church, so called from the parish clerks of the City of London, who used formerly to meet there for the purpose of representing certain parts of the Scriptures in a theatrical manner. "These wells," says Fitz Stephen, who was in the service of the famous Thomas à Becket, and wrote a life of that celebrated prelate, "may be esteemed the principal, as being much the best frequented, both by scholars from the schools, and the youth of the City, when in a summer's evening they were disposed to take an airing." Near to Clerks' Well was Skinners' Well, where plays were in ancient times performed.

More eastward, towards the Charter House, were Fagges-well, Todswell, Loders-well and Red-well, which, with another in Smithfield, called the Horse Pool, united to form the River of Wells.

"Dame-Annis-the-Clear" Well, in Hoxton; and, somewhat west of this, Perilous Pool, now called Peerless Pool.

Without Cripplegate there was a large pool supplied by Crowder's Well, on the north-west side of St. Giles's churchyard.

There was a fountain in New Palace Yard, Westminster.

There were two wells in Shadwell, one of which, a fine and clear spring near to St. Paul's church, gave this suburb its name.

Besides those herein enumerated there were many smaller ones, the situation of which may still be discovered by the names of the streets and alleys or places in their neighbourhood, such as Monks' Well, Bride Well, formerly called Bridget's Well, &c.

London supplied by Conduits subsequently to 1236.

Stow says, "The said River of Wells, the running water of Wallbrook, the bournes afore named, and others the fresh waters that were in and about this City, being in process of time, by encroachment for buildings and otherwise, utterly decayed, and the number of citizens mightily increased, they were forced to seek sweet waters abroad, whereof some" *springs*, "at the request of King Henry the Third in the 21st year of his reign, were, for the profit of the City and good of the whole Realme thither repairing, granted to the citizens and their successors by one Gilbert de Sanford, with liberty to convey water from the towne of Teiborne by pipes of lead into their City." The Tybourne rivulet ran though Tothill Fields to Scholars' Pond, and thence into the Thames; it is now a common sewer. The grant was made in 1236; the work was commenced in 1285: the waters from Tybourne were conveyed by a six-inch leaden pipe to Charing Cross, and from thence to several conduits in the City, the first and greatest of which was erected at the Cross in Cheapside, at the end of Wood Street, in 1285, the distance being about three miles and a half, and for the *first time* water was conveyed by pipes into the City.

In 1401 the prison-house called the "Tun on Cornhill, was converted into a cistern for the Tybourne water, and was afterwards called the Conduit on Cornhill.

In 1423 water was brought from Tybourne to Billingsgate, Paul's Wharf, and to a cistern in the wall of St. Giles's church, Cripplegate.

In 1430 water was brought to the Standard in Cheapside, near Honey Lane.

In 1432 water was conveyed to the gaols of Newgate and Ludgate.

In 1138 water was brought from Tybourne to conduits in Fleet Street and Aldermanbury, and from Highbury to a conduit opposite Cripplegate church.

In 1139 the Abbot of Westminster granted the City one head of water, containing about 890 square yards, or the sixth of an acre, together with all its springs in the manor of Paddington, *provided* the intended work did not *draw* the water from the ancient wells in the manor of Hida; showing by this proviso that four hundred years back it was discovered that any great draught from one well would be likely to leave the other neighbouring wells dry. This grant was confirmed by Henry the Sixth in 1441; and other advantages were granted by a writ of Privy Council, to enable the citizens to bring water by means of leaden pipes under the ground for "above three miles" to a conduit in Cheapside, which was erected in place of the old one at the Cross, which Cross was also re-edified at the same time; and this conduit was used as a reservoir for the supply of other conduits. The water was conveyed from the springs to cisterns at Tybourne, from thence to Charing Cross, and thence to the City.

In 1443 a new conduit was erected near St. Paul's Gate, at the upper end of Cheapside.

In the Old Bailey, a little lower than the Sessions House, was a large cistern with divers cocks, which received the waste water from the prison of Ludgate, for the use of the neighbouring inhabitants.

In 1471 a fresh supply of water was brought by leaden pipes from Tybourne to a conduit erected in Fleet Street, at the end of Shoe Lane, and to other conduits, for the benefit of the people; viz. "for the poor to drink, the rich to dress their meat."

In 1478 a cistern was added to this conduit to hold the waste water, and another at Fleet Bridge.

In 1491 a conduit was erected in Grasse (or Gracechurch) Street.

In 1498 a conduit was erected at Oldbourne Cross, and was again new made in 1577 by William Lamb, citizen, who having drawn together several springs of water into a head at the upper end of Red Lion Street, which was called Lamb's Conduit, conveyed the same to a conduit on Snow Hill, by a leaden pipe 2000 yards long.

In 1509 a stone conduit was erected in the Stocks Market which stood at the north corner of Wallbrook.

About the year 1513 a conduit was erected in Bishopsgate Street.

About the year 1528 a conduit was erected at London Wall.

In 1535 water was brought from Hackney to a conduit erected in Aldgate.

In 1543, notwithstanding the vast expense the citizens had been at in bringing water to, and erecting conduits in, the City, the supply was very inefficient; and an Act was passed in the 31st of Henry VIII. empowering them to bring water from Hampstead Heath, St. Mary le Bon Hackney, and Muswell Hill, upon their compensating the owners of land for damage done by digging or otherwise.

In 1546 water was conveyed in great abundance from divers springs lying between Hoxton and Islington to a handsome conduit erected at the west end of St. Margaret's church, Lothbury.

The Charter House was supplied from White Conduit Fields; Christ's Hospital, from the Devil's Conduit, north-east of Brunswick Square.

Stow mentions amongst the remarkables in the City of London a well at Aldgate curbed with stone of a great depth, and rising into a house two stories from the ground, which is peculiar, "for I have not seen the like in all this City to be raised so high."

There were other conduits of less note than those now enumerated, and wells with buckets or pumps in Threadneedle Street, Leadenhall Street, &c.

Sir John Evelyn writes that about the accession of Queen Elizabeth, in 1558, the waters of Dame-Annis-the-Clear Spring at Hoxton were carted to the breweries in London, at an expense of 800*l.* per annum; and about the same time wells were dug and pumps erected in every corner of the City and suburbs.

Water raised from the Thames by Machinery.

In 1568 a conduit was erected near the top of Dowgate Hill, which was supplied with Thames water by means of a gin, or machine for raising water, fixed near the river,—most probably what is termed a horse-wheel.

This appears to have been the first machine used in London for raising water for the supply of the public to a higher level than could be done by the common pump.

Thus it appears that London was supplied, first, by running brooks and springs, and secondly, when these failed, by water brought from a distance through leaden pipes, the sources being at a sufficient elevation to allow the water to run into the conduits. In a few instances the waste water from these conduits ran into cisterns adjacent to them, for common or public use; but water was of too much value at that time to allow this to be done generally, and in cases of fire the supply was miserably deficient, which, together with the circumstance of timber being the common material used in the buildings, accounts for the number of destructive fires in ancient times.

Although bringing water by means of pipes from distant sources was a great improvement, so far as respected an increased quantity; nevertheless, the inconvenience and expense of carrying it from the conduits to each house still existed, and it was not until the erection of the London Bridge Water-works, in 1582, that this difficulty was overcome, when the principle of conveying water into dwelling-houses by means of small lead-pipes was adopted; this, the greatest improvement in the mode of supplying water, by substituting the power of machinery for human drudgery, has not been surpassed, and is the plan now used, two centuries and a half after its first introduction; improvements have been made in the practice of it,—the principle remains unaltered.

London Bridge Water-works.

In 1581, or 1582, Peter Maurice, a Dutchman, obtained a lease of the City of the first arch of London Bridge, on the North side, and erected a water-wheel, to be worked by the tide, and a set of force pumps to raise Thames water for the supply of the neighbourhood. The water was raised to the top of a wooden building 120 feet high, and passed from thence through pipes to supply the dwelling-houses in Thames Street, New Fish Street Hill, and Gracechurch Street, as far as a Standard on Cornhill, which was erected in the middle of the street where the four ways meet. The water which was to spare, after supplying the beforenamed streets, flowed from the Standard through four pipes branching to Bishopsgate, Aldgate, the Bridge, and Wallbrook, which supplied the dwelling-houses in the neighbourhood, and cleansed the gutters in these streets. The site of the Standard was supposed to be the highest ground in the City. The quantity of water raised was equal to about 3,470,030 imperial barrels per annum, or an average quantity of 246 gallons per minute, or about $\frac{3}{4}$ths per cent. of the quantity raised by the water-works for the supply of the Metropolis at present. There were 16 pumps worked by this wheel, each 7 inches diameter and 30 inches stroke. Mr. Smeaton ascertained from registers that the pumps made 3025 strokes per tide; and, as there are 708 tides per annum, (allowing one-fifth for loss through the valves, according to Dr. Desagulier's statements,) the quantity raised may be calculated. Improvements, however, had been made before the above particulars of the pumps were published, and therefore the quantity given will be the extreme probable quantity raised in 1582.

In 1583 or 1584 machinery was fixed in the second arch.

Improvements were made and the works continued in Maurice's family until 1701, when they were sold, (after an engagement had been made with the City for a lease of the fourth arch,) to Richard Soams, citizen and goldsmith, for 36,000*l.* Soams formed a company, and divided the property into 300 shares of 500*l.* each. In 1761 machinery was erected in the third arch; in 1767 machinery was erected in the fifth arch, and also in the second arch from the Surrey side for the supply of the Borough. The large wheel erected in the fifth arch by Mr. Smeaton was added in consequence of the reduction in the fall of water occasioned by enlarging the water-way under the bridge when two arches were thrown into one. And about this time an atmospheric engine was erected of ten horses' power to assist the wheels at neap tides, and as a safeguard in case of fire happening in the City at the turn of the tide, when the wheels, of course, could not work.

In consequence of the City being obliged to pen up the water to work the wheels, according to an Act passed in 1756, in the 29th of George II., the blocking up of the arches became such a nuisance to the navigation of the Thames, that an Act was obtained in 1822, the 3rd of George IV., for the removal of the London Bridge Water-works, and they were removed accordingly, and the district was supplied by other companies, chiefly by the New River. At the time of the destruction of these works the number of tenants was 10,417, and the quantity of water raised by them was equal to 39,484,000 barrels per annum, or 2704 gallons per minute; showing an increase equal to twelve times the quantity first raised in 1582 by Peter Maurice.

In 1583 two conduits for Thames water were erected near to Old Fish Street Hill.

In 1594, for the better supply of the City, Bevis Bulmer erected a large horse-engine and four pumps at Broken Wharf, to raise Thames water for the inhabitants of Cheapside, St. Paul's Churchyard, Fleet Street, &c., which, Maitland says, was removed previous to the date of his work, 1756, on account of other companies being able to supply water at a cheaper rate.

New River Head Water-works.

The greatest and most splendid work that was ever undertaken for the supply of a modern city with water was commenced in James the First's reign.

In 1605, the 3rd of James the First, the supply of water was found to be inadequate to the wants of an increased population; and as at that time the discovery of the steam-engine had not been made, it was necessary to seek abroad for more powerful springs of water than had hitherto been discovered, and at a sufficient elevation to allow the water to run to London: these were met with in the neighbourhood of Hertford, above twenty miles north of London, and the citizens conceived the vast plan of bringing these springs by means of a channel to Islington, and for that purpose obtained an Act of Parliament, empowering them to bring a stream of water from the springs of Chadwell and Amwell in the county of Hertford, between the towns of Hertford and Ware. By this Act, 3rd of James the First, they were empowered to make a "trench, channel, cut, or river"; the width of the ground to be purchased, being limited to 10 feet; and as these springs were situated in the valley of the river Lee, and, consequently, ran into the said river, they were bound to compensate, not only the owners of property through whose lands the river was to be carried, but also, "all such persons as shall sustain any damage, loss, or hindrance, in their mills standing upon any of the rivers or streams from which the water shall be taken through the said new cut, or river." That this was a proviso of great consequence may be supposed, when at the present day it is stated that one of the springs yields a quantity of water equal to about 3770 imperial gallons per minute, or 54 millions of barrels per annum.

Surveyors were employed by the City to plan the execution of the work; but it was discovered that, as the Act limited the width of the property to be purchased to 10 feet, it would be impossible to convey the waters across the hills and valleys to London: the City therefore applied to Parliament again the following year for power to make tunnels, where necessary, either to be laid in the earth or formed upon arches, and an Act was passed accordingly in the 4th of James the First. Even with these additional powers the course of the river was extremely circuitous, being above 40 miles in length.

Notwithstanding the powers which had been obtained, it appears that the work was not executed until some years after.

In 1608 Sir Hugh Myddleton, citizen and goldsmith, offered at his own charge to carry the Acts of James into execution; and to this great and enterprising man were the inhabitants of the Metropolis indebted for one of the greatest blessings that could be conferred upon any city.

In 1610 the citizens, by an Act of Common Council, made over their powers to Sir Hugh Myddleton; and in 1612 this Act was confirmed by an indenture.

The work, however, appears to have been commenced in 1608, and was completed in 1613.

Maitland states that Mr. Henry Mills, the then engineer to the Company, measured the length of the river accurately in 1723, and found it to be 38¾ miles and 16 poles, to which it was reduced by the contraction of its sinuosities above two miles.

That there were 215 bridges over it, and that it was carried over two valleys in wooden troughs lined with lead, one at Bush-hill, being 660 feet long and 30 feet high; and the other at Highbury, 462 feet long and 17 feet high. He further says, "As this New River is in some places wafted over hills and vales, so in others, mole-like, it forces its way through subterraneous passages, and arriving at the place unjustly called its Head, in the neighbourhood of Islington 'tis ingulfed by 58 main pipes of bores of 7 inches; whereby 'tis conveyed into the several streets, lanes, &c. of the City and suburbs of London, to the great convenience and use of the inhabitants, who, by small leaden pipes of half inch bore, have the water brought into their houses;" the number of tenants amounting in 1756 to 30,000.

It was opened and the water admitted into the basins at the New River Head at Michaelmas, 1613, with great pomp on the day that Sir Thomas Myddleton, brother to Hugh, was elected Lord Mayor.

In 1619 a charter of incoporation was granted by James I. to Sir Hugh Myddleton, citizen and goldsmith, in conjunction with other wealthy citizens, and they were styled "the Governor and Company of the New River brought from Chadwell and Amwell to London." It empowered them to improve the river, to prevent nuisances being committed therein, *under penalty of the King's displeasure*, subject to the laws for the contemners of the King's authority; and, *under the same penalty*, all other parties were prohibited bringing water for the supply of the Cities of London and Westminster, and the Borough of Southwark, without a licence from the Governor and Company of the New River.

The King subscribed towards the undertaking, and was thereby entitled to a moiety of the profits. The work was said to have cost 500,000*l.*: the capital was divided into 72 shares, of which the King had 36; but so poorly did the scheme answer at first, from ignorance of the great advantages that the Metropolis would derive from this splendid work, that Sir Hugh Myddleton, who had spent the whole of his fortune, was ruined, and the proprietors did not for 30 years divide more than 5*l.* per share, or about 1s. 6*d.* per cent. The King, however, who was entitled to a moiety, relinquished his share, reserving only 500*l.* per annum out of it. Although the King's share was in private hands, they took no part in conducting the affairs of the Company.

Previous to the year 1738 the supply from the springs was found to be insufficient, and arrangements were made with the trustees of the river Lee, to enable the New River Company to abstract water from the said river. This was done, first by pipes, and afterwards by a cut and trough into the New River, the dimensions of which were determined by Act of Parliament, passed in 1738, in the 12th year of the reign of George the Second.

This supply, however, was not found to be sufficient, although equal in the aggregate to nearly 17 millions of gallons per diem, or nearly 172 millions of barrels per annum; for in 1822, when the New River Company undertook to supply the London Bridge Water-works districts, it was one of the conditions that they should have a steam-engine to pump from the Thames, in case of failure in the supply of the New River, occasioned by frost or draught: and a 100-horse power engine was accordingly erected at Broken Wharf.

Objections having been made of late years to the water *occasionally* raised by this engine from the Thames, and to the exposed state of the New River, allowing boys to bathe in it, and other nuisances; the Company, upholding the character for enterprise which was bequeathed to them by the great founder of their works, are now applying to Parliament for powers to improve their supply, by relinquishing their station on the banks of the Thames, and in lieu thereof, raising water from the river Lee; and also by fencing in the New River to prevent nuisances being committed therein.

(To be continued.)

BRITISH MUSEUM.—No. V.

(From the Times.)

EGYPTIAN ANTIQUITIES.

THE collection of antiquities in the great saloon of the British Museum, unconnected with the edifices of which they formed part, to the artist are comparatively useless. The monstrosities they represent can neither excite his emulation, nor improve his taste; while to the general visitor they are only regarded as matters of curiosity: he lingers round the mutilated blocks of granite, in vain endeavours to find the meaning of the strange and uncouth figures he sees so innumerably engraved upon them; on turning to the pages of the synopsis, he simply finds the names of Amenothoph, of Rameses, of Hopth, of Shishak, or of Pthamenoph, and his curiosity remains unsatisfied. A short and more particular description of some of the most important may not be unacceptable.

In the central room a case has lately been opened, in which are two figures, apparently designed to represent a mother and daughter. In beauty of design and execution they are hardly surpassed, if equalled, by any in the collection; they seem to belong neither to the temple nor the tomb, and, whatever they may be called, possess all the appearance of family portraits. They are sitting on a couch, the legs of which terminate in lion's paws, and possess more of the Greek than Roman fashion; the height of the elder figure is 5 feet 6 inches, that of the younger 5 feet 2 inches; in the right hand of the mother, which is extended downwards, is the mysterious instrument resembling a key, called the "tau," which is commonly a mark of the priesthood; the other, which is singular in Egyptian sculpture, is placed upon the daughter's; the faces of both are handsome, that of the youngest might be thought beautiful; the expression of innocence and modesty is finely pourtrayed; the eyes are large, the lips have nothing of the Ethiopian character, the mouth is beautifully shaped, the nose small and delicately formed, and happiness is thrown over the countenance; the figure is slender, the shape of the bosom and shoulders perfect; the hair, which is in a thousand curls, covers the ears, and on the forehead is so arranged as to form a tiara; the dress descends nearly to the ancle, and is intended to represent the finest muslin; around the edges of which is an edging apparently of lace; it is crossed over the breast, and passes through a ring, from which is suspended an amulet in shape like a cross; the feet are bare, the hand and arm perfect. A great likeness is observable in the faces of both the figures, but the lips of the elder are thicker, and the nose and face are altogether more Egyptian; the hair of the latter is also curled, but is not so thick as that of the younger, and the ears are shown, in which are earrings; the dress, which is much shorter, is not so full over the person, but equally fine in the texture; on the feet are sandals, the fastenings of which are minutely executed, and are entirely different from the Greek or Roman style. Some remains of colours are to be observed on the dress, blue and red. There does not appear to be any hieroglyphical inscription on it. Immediately under the columns which separate the saloons are two colossal lions which were given by Lord Prudhoe; they are of red Egyptian granite; on each are two tablets or cartouches, on which the learned have read the names of Amenothoph, the second and third; there are also on them two other tablets, the characters of which have not yet been deciphered; they were brought from Nubia, from Delphi, 500 miles beyond the Cataract. The attitude which is given them, although from the locality whence they were removed evidently betokens their great antiquity, is more true to nature than in the generality of similar figures of Egyptian design; one is lying on the right, and the other on its left side; the right fore leg in one is under the body, all but the paw; the left is stretched across the chest, and the paw, turned flat down, rests on that of the right, the under of which is turned upwards; thus the two paws meet like two hands when brought flat together; the eyes are very long, and have much resemblance to those of Egyptian human statues. There are two small lion sphinxes which much resemble these; they were found by Captain Caviglia when he uncovered the sphinx of the Pyramids, in a small temple, placed between its legs; they are of soft calcareous stone, and have been painted red; their length is about 50 inches; one has a head in the style of the sphinx, and on a plinth are some figures, which are no part of the original design, they are not hieroglyphics. Of the other, the lower part of the face is gone: this has also a low head-dress, and a mane carved in lines down the breast, and what is singular, neither of them possesses much of the Egyptian character, though found in such a situation. No. 11 is the figure of a hawkheaded sphinx, which was found by Belzoni at Ipsamboul. The ram's head in this room, which formed the head of a colossal sphinx, was taken from the avenue at Carnac, and is of soft calcareous stone; the face is 3 feet 6 inches in length, and the horn in the curve 4 feet 11 inches, the tip of which is broken off; on the top of the head is an oblong hole, 4½ inches by 4 deep. From the spirit shown in the sculpture of this head, as also in those of the lions, it is to be seen that the Egyptians excelled far more in their delineation of animals than of the human form; that hardness and inanimation, which is the characteristic of the latter, is not to be complained of in the other. What was the origin of the sphinx, and they are found in Europe, Asia, and Africa, what mystery was hidden in so strange a shape, and still wrapped in obscurity, the general opinion of antiquaries, that a lion's head, united to a woman's body, was to denote the rise of the Nile, when the sun is in the signs of Leo and Virgo, will not suit those with a male head or a ram's head. Winkleman thinks the Androsphinx typifies the male and female principles of worship united in one form, and it is so found in India; the Greek sphinx was a female and a lion; the Egyptian and Jewish, a lion with a man's head; in Arracan, it is a female; in Java, half a woman and half an elephant; and in India the fourth incarnation of Vishnu is a man lion. There are in this room two obelisks of black marble; they are the only ones in the Museum; the one on the right as you enter is that mentioned by Niebur in his travels; it has been broken into two pieces: they are now together; the lower part, which is perfect, is about 8 feet in height; it was found fixed into the side of a doorway of a house in Cairo, and the broken part served for a sill; the north side has a cartouche under the usual symbol of the goose and disc, and another perfect, supposed to contain the name; they are repeated on the opposite side, and nowhere else; the hieroglyphics on the north and south sides are the same; those on the east and west are different, but resemble each other; the first are much better executed than the other; the bird is perhaps one of the best specimens of sculpture found in Egypt; the arch on which it is chisseled out is rounded with great skill; the shadow thrown by the edges formed by the erasion in the stone, added to the shadow cast from the rounded part on the deep incision, gives a fine relief to the lighter and higher parts; the feathers of the wing are also beautifully raised, and the eye is well delineated. The one opposite, which is about the same size, is not so well executed; it has the same cartouche cut on the four sides; the hieroglyphics are the same on both of these obelisks, but differently placed; the sistrum is shown on both, and what is supposed to be the proper name on the Alexandrian sarcophagus, as also the prenomen, is the same which appears on these. It was the opinion of Denon that obelisks and gateways which are often found insulated before the temples were votive offerings to the collective gods. The colossal head on which is the mitre, called the Teshr, was found by Belzoni at Carnac, east of the Nile; it is of red granite, and is highly polished, and of much larger dimensions than the one opposite, called the lesser Memnon; the face has much more of the Ethiopian character, and does not possess the softness which is seen in the other, and is evidently of an earlier date; the height from the top of the mitred crown is 10 feet; the beard-case and left ear only are destroyed; the colossal arm lying near it belonged to this statue, and from its being straight and in a falling position shows it must have been an upright one; in the hand are the remains of a staff or sceptre. The cap is fastened with bands under the chin. From the position of the arm and head its height must have been at least 26 feet, and it is observable in this, as in almost all the Egyptian figures, that the ear is placed too high on the head.

The colossal figure marked 21 was discovered in the ruins of a temple behind the Colossi at Thebes, between the Memnonium and Medinet Abu: it is an exact model of the great figure of Memnon at Thebes, the exact height of which is 70 feet; it is in a sitting position, and has a close-fitting cap on the head, on the front of which is the aspic serpent. The beard and lower part of the chin are broken. The stone is a breschia, and looks black, but it is a dark gray, and has bright yellow particles in it, and is the only statue of that kind of stone in the collection. The hair is curiously gathered behind, and, from a number of radii collected in a convex form, is gathered into a long tail; it has a nether garment, of corduroy appearance, attached to a belt round the waist, and overlaps in parts on the thighs, on which are extended the hands, which are badly executed. At the back of the throne is a square column, and the cartouches there inscribed contain, as we are told, the name of Amenothoph or Memnon, being the same as those on the Theban colossus.

A colossal head of Jupiter Ammon, of white stone, marked 30, is finely executed; it was in the collection of Mr. Salt, found by Belzoni, at Carnac. Part of the face is destroyed, but as it remains, the difference of expression observed on viewing it is remarkable. In the front it possesses the general character of Egyptian composure; on the northern side it is grave and severe, and on the eastern it has the same smile as is seen on the face of the lesser Memnon.

Another head of equal size, on the left of the room as you enter, is the only Egyptian one in the Museum on which the beard is seen; in all the others it is placed in a sort of case, but here it is sculptured on the stone; flat lappets descend on each side of the head, the breadth of which are of the same size as the fringy beard. The stone of which it is formed is a brownish breschia, peculiarly difficult to cut. The great sarcophagus on the left, near the entrance, given by Colonel Vyse in 1839, is of red breschia, and is well deserving inspection. The hieroglyphics are highly finished; they are not so numerous as those on the tomb of Alexander, or the one opposite called the Lovers' Fountain, but of better execution. It has a lid of circular form, which fits with a ledge; there is a band of hieroglyphics on each side: in each band are 12 figures 4 inches in length, all different, and divided from each other by a tablet of inscriptions; 11 of these figures are faced by one at the end, a band of hieroglyphics reaches halfway along the cover, another crosses this, and then there are 6 more, 3 of which are but half the length, to give room for 3 figures of mummies, of which there was probably 3 within the monument. Above this there is a face deeply cut, the features of which are completely of the negro character. It has the usual "oskh" or cunicular tippet worn round the neck. The length is 9 feet, and the breadth 3 and a half. The colour of the stone forming the top is much lighter than the lower part of the sarcophagus. No. 10, which is supposed to have been the tomb of Alexander, consists of a single block of stone ten feet in length, four in height, and about five in breadth. It is a particular kind of prismatic conglomerite, resembling that which is under the second porphyry formation, and is entirely covered with hieroglyphics in lines. On his death, we are told by Curtius, his body was enshrined in golden chasework, over which was put a purple vestment, and then his armour: on his arrival at Alexandria it was there deposited, but whether in this sarcophagus or not has been matter of dispute. He was worshipped as the thirteenth god of the Egyptians; three centuries after his death his body was seen by Augustus. Tacitus says the tomb was again opened by Caligula, and the breastplate taken out and worn by him. When the body was removed is unknown, but the Mahometans had always revered and concealed this sarcoghagus from the Christians till seized on by the French.

The engraved tablet of black basalt, called "the Rosetta-stone," the "*crux antiquariorum*," contains three inscriptions—one in hieroglyphics, one in the ancient spoken or enchorial language of Egypt, and the other in Greek. The learned have read, that they record the services which Ptolemy V. had rendered to his country, and that they were engraved by the order of the priesthood assembled at Memphis, for the purpose of investing him with the regal powers. Till the discovery of this stone, which was found by the French in digging the foundation of Fort St. Julian at Rosetta, notwithstanding the labours of Kircher and others, the innumerable inscriptions and the monstrosities which are found engraved or painted on every relict of Egyptian antiquity remained matter of doubt and wonder, and were veiled in the darkness of conjecture. The arrival of this stone was therefore hailed with equal joy by the learned, as would the recovery of the key of an unpickable Bramah by its unhappy loser. Upon the engraving of this block a wondrous system has been raised, which, if it is perfected, is destined to enlighten us in "all the wisdom of the Egyptians," and lay open to the inquiring mind of the 19th century all the knowledge which is thought to be contained in those inscriptions, the amount of which, taken collectively, would fill 10,000 volumes. Some short account of the deciphering system pursued may not, in connexion with the whole of the Egyptian monuments, be unacceptable.

The first author who mentions the writings of the Egyptians says, they had two kinds of characters, one called sacred, and the other popular: but he does not say that they had any affinity with each other. Diodorus Siculus mentions the same, with the addition that the first were peculiar to the priests, and the other was taught to all. Concise as this is, it is all the information these authors give. The next is the celebrated passage in the works of Clemens Alexandrinus, in which the different kinds of writing are given with considerable precision. He says there were three kinds—the Epistolographic, the Hieratic or sacred, and thirdly, the most complete of all, the Hieroglyphic, which he tells us is expressed by means of the first or initial element of words, that is, by reference to the initial sounds of words which denote these objects in the spoken language of the country. Upon this scanty foundation the most extraordinary theories have been built; the six folios of Kircher, according to his interpretation of the hieroglyphical inscriptions, which succeeded equally whether he began at the beginning, the middle, or at the end of the text, are found to be filled with the cabalistic science and strange fancies of a refined system of Dæmonism. The Abbe Pluche has discovered that they are all astronomical, or expressive of the doctrines connected with the science of astronomy, and the division of time in the calendar; and the author of a work entitled *de L'Etude des Hieroglyphiques*, published at Paris in 1812, found in the inscription on the temple at Dendera a translation of the 100th Psalm of David, a foreign language, which most likely the inhabitants of the country never understood. Count Palin has persuaded himself that the hymns of David are but Hebrew translations of the consecrated rolls of Egyptian papyrus. All these fantastic reveries have, however, given way to the system of Dr. Young, the invention of which has been disputed by M. Champollion; he followed the idea of Warburton, that the hieroglyphic or sacred character, was not so called because peculiarly appropriated to sacred subjects, but that they constituted a written language applicable to all the purposes of life, that they were not used to represent things or ideas, but that they represented sounds or words, that they were alphabetical, and that they exhibited things or objects, the common names of which in the spoken language began with the sounds it was wished to express. To make this more intelligible we give the following example:—If there was no other manner of writing than by pictures, or symbols, and the spoken language of England the same as it now is, and if it was required to write the name of James, this name being a mere sound could not be intimated to any one by a picture or symbol; but if it was understood that the key of this name was to be obtained by reference to a series of pictures of familiar objects, the names of which in the spoken language begun with the sounds which were successively to be expressed, and which when taken together in that order made up the name, thus, for the sound now expressed by the letter J the figure of a jug or jar was set down, for an A an ape or an acorn, for an M a man or a mouse, and for an S a spear or a spur; the name of James would then by a sort of symbolic acrostic be intimated to all who read the figures in the spoken language. This is the basis of the principle of Dr. Young, De Lacy, and Champollion, and the literati have proceeded upon this to decipher the Egyptian hieroglyphics. To what extent they have succeeded yet remains a matter of doubt; but in consequence the visitor to the Museum, when passing on from viewing the dilapidated remains of Egyptian sculpture in the lower saloon, regretting his ignorance of the strange writing and figures on all of them engraved, is agreeably surprised when he enters the gallery above to recover his mistake; here he finds all is known and deciphered; he reads these are the remains of Pefaakons surnamed Onkhounmofie, auditor of the Royal palace; that the next is Pamanoum, priest of Ammon; that a lady lying near is Iatsbahem, daughter of Petkons, porter of Amoun, and born of Tauaak, lady of the house; he is startled at the immortality; that another is Pénamaum, an incense-bearer, son of Olmofie, son of Hor and of Baenrow, daughter of Saklous; and he supposes that want of space has alone prevented a full account of their lives and actions, easily to be read on their inscriptions, from being given in the synopsis; but he will find on inquiry that serious objections may be raised even to the validity of the names attached, much more to any particular account of their offices or actions.

All the modern expounders of hieroglyphics have raised the structure of their expositions on the trilingual inscription seen on this Rosetta stone, and principally depend upon it. Dr. Young, the most celebrated of them all, did not begin his researches till after its discovery; he knew nothing of it, but from the French account, and it is upon that account alone that the genuineness of the inscription depends; it is true that some other stones with triplicate inscriptions have been found, but that would be the necessary consequence of the first being made: the size and nature of all of them evidently show that they were not in ancient times kept concealed, and if they are so ancient and genuine as we are to believe, why did not the Roman writers go at once to these inscriptions scattered about the country to interpret that which they all regret was lost? It may be said that it would be almost impossible to have forged the inscriptions on this stone, it would only have made the last or Greek one, and when we look at the manufacture of ancient Etruscan vases and cameos in Staffordshire, the tricks of the Parian marbles, the manuscripts of Shakspeare, the copies of Raphael, and read the astounding tale that Professor Houlton, of the Medico Botanical Society, produced a bulbous root found in the cranium of a mummy, in a situation in which it had probably lain 2,000 years, that it germinated when exposed to the atmosphere, though when discovered in a state of perfect dryness, and on being placed in the ground it grew with readiness and vigour, and also know that mummies are manufactured every day, and consider the authority on which it rests, the impossibility of this monument not being genuine is very difficult to believe. In Pompeii articles are constantly buried to be found when wanted, and it has always been observed that the higher the rank of the visitor to those remains the more successful is he in his antiquarian search. There may be 100 Rosetta stones discovered, but the more that are found the more difficult it is to account for the ignorance of Clemens and others on the subject. The plan both of Champollion and Young, of making many phonetic signs for one letter, will make them speak whatever the expositor desires, and proves that arbitrary figures which are not hieroglyphics may be made to give any meaning he may please. If this inscription on the Rosetta stone is genuine, why did not Clemens, who lived at Alexandria, go to it to remove his ignorance, which the passage in his work on the subject proves, and why did not Strabo also? They both could have read the Greek, which the best Scotus can now hardly understand. But what more clearly proves that the meaning of the hieroglyphics was unknown in the Roman times, is the fact, that one of the first emperors offered a reward for the deciphering of those on an obelisk he brought to Rome. The ignorance of Diodorus, Strabo, and Clemens is a pretty good proof that the inscriptions found on the trilingual stones are modern fabrications, else why are so few found, and none on the temples and statues themselves? Whether the French seavans were the inventors and fabricators is certainly difficult to determine, but that is far more likely than that the authors we have mentioned, and the Roman emperors, should have been ignorant whether hieroglyphics were in use in their time or not. Neither Strabo nor Diodorus says that the hieroglyphics were known in their day; yet if they had been, why have not those authors quoted them in their histories of the Egyptian mythology? It is more than probable that these inscriptions were never intended to be read but by those who had the tradition of their meanings, and that the priests having been massacred in the Persian conquest by Cambyses, that tradition was lost. The same would have been the case with the traditionary learning of the Mexicans had not the Spaniards preserved it. Both Dr. Young and Champollion have found by their process the names of Roman emperors on the same monument with those of the Pharaohs and Ptolomies, in situations where they could not have been erased. How can they account for this? If the names of Ptolemy and Cleopatra, and the Romans, are to be found on the buildings and obelisks written in hieroglyphics, of course they could not have been lost in the time of Strabo and Clemens, yet any one who attentively considers the passage in his work, and that passage is the foundation of all modern explication, must come to the conclusion that the obscurity in which he has enwrapped it was purposely done to conceal his ignorance of that which he pretended to describe.

To the plan of Dr. Young and other learned expositors of reading the hieroglyphics by applying the first letters of Egyptian words of the common vernacular tongue now in use—viz., the Coptic—it would be satisfactory to imply that it must always have remained the same, or nearly so. It is true, we are told nothing changes in the East; but, notwithstanding, it is impossible not to believe but that tongue, admitted to have always been the spoken language of the country, passing through the crucible of conquest by the Ethiopian, the Shepherd Kings, the Israelites, the Persians, the Greeks, the Romans, and the Saracens, during a period of 3,000 years, must have been so dislocated and altered as to have rendered it impossible to read the symbolic or hieroglyphic language of Sesostris in the Coptic or the oldest Coptic books now extant.

RAILWAY CURVES.

In compliance with the request of several members of the profession, we have carefully perused the communications of our correspondents on the subject of railway curves, and, after a careful examination of the various methods therein proposed, we cannot but concur in their opinion, that the question has not yet been satisfactorily settled. We therefore engaged Mr. Aristides Mornay, a gentleman well known for the accuracy of his calculations, to construct a set of tables to facilitate the execution of a plan which we shall presently explain, after having offered a few remarks on the proposals contained in the above mentioned communications, which were published in the Journal during the past year.

In the January number Mr. Murray, under the signature of "A Sub.," proposes as an improvement upon the system of running directly from a straight line to a curve of $1\frac{1}{2}$, 2, or $2\frac{1}{2}$ miles radius, that a curve of 3, 4 or 5 miles radius for a short distance should be made use of to connect them. He adds that projectiles (where the resistance is equal) assume the parabolic curve, to which the plan he proposes is an approximation.

This observation about projectiles is properly answered in the number for March, by "R. W. T.," who also justly observes that "if the curvature is not equable," which would be the case if Mr. Murray's advice were followed, "some parts of it must be sharper than if the same radius were used all through."

In the April number Mr. Ely denies the correctness of "R. W. T.'s" statement, on the ground that Mr. Murray's object is to "begin curving sooner, and make the radii of portions of the curve *greater*." This objection would only obtain, if the object were, besides beginning with a curve of greater radius, to terminate also with a curve of greater radius, which would join the straight continuation of the line farther on than the single curve of uniform radius originally supposed. This however was not Mr. Murray's intention, as is evident from his own diagram and description in the November number. He has assumed a certain point to be arrived at, without considering that the direction of the continuation of the railway is also determined before-hand. These two conditions being given, it is obvious that the junction must either be effected by means of an uniform curve of a radius determined by the given circumstances, or by commencing the curve sooner with a longer radius, and terminating with another of shorter radius.

With respect to the queries of "An Assistant Engineer," in the April number, it appears Mr. Bruff has not exactly comprehended the first, or at least has not expressed himself very clearly. If the case is as represented in "An Assistant Engineer's" diagram, the solution of his problem is impossible: it would be necessary to use a curve of *greater*, instead of *less* radius to join the two given curves. It would, however, be better, if these two curves are indispensable, to connect them by a tangent, as suggested by Mr. Bruff; or, if the two given curves could be altered, it would be still better to increase their radii, so as to make them meet, and form an S curve together. We consider this far better than the plan proposed by "R. W. T.," in the September number, for two reasons: *first*, because the line is shorter, and *secondly*, because the curves are not so sharp. If it were desired to begin one of the curves farther up on the tangent, as recommended by "R. W. T.," the distance to be gone upon the tangent may be found much more easily, and with mathematical correctness by a method which would immediately suggest itself to any one at all conversant with geometry.

We now come to the second query, the solution of which is the main object of these remarks: viz. "Which is the most correct mode of setting out railway curves?" Mr. Foster Charlton's method, recommended by Mr. Bruff, and extracted from "Weale's Scientific Advertiser," is correct; but we do not think it practicable, as it is necessary to construct a triangle of which the lengths of the sides are given, which operation must be exceedingly difficult when two of the sides are several chains in length. "B. W. T.'s" method, given in the May number of our journal, is incorrect, and is not sufficiently explained to enable any one to put it in practice.

The mode described by "Surveyor," in our June number is a correct one, and partly the same as that we propose; but the measurement of the angle contained between the two straight lines to be connected is perfectly unnecessary, and he does not appear to have been prepared with a practical mode of laying off the second tangent.

The method described by our correspondent "M." in the July number, as that usually adopted, besides not being mathematically correct, must be attended with much difficulty in practice, on account of the necessity of constructing triangles whose sides are given; but that proposed as a substitute, although perfectly correct, if the work is accurately performed, is nearly, if not quite as difficult of execution as the former.

It only remains for us now to explain the method we propose for setting out railway curves, which we think will be found to be applicable in all cases, and generally easier of execution than any other *correct* plan. The explanation is illustrated by reference to the accompanying diagram.

Let A″ A be the direction of the railway before curving, and A the point at which the curve is to commence. Produce A″ A to A′, making AA′ any convenient length, and at the point A′ erect the perpendicular (A′ B or offset) on the line AA′, which is a tangent to the required curve, and make A′ B (the offset) equal to the length given in the column *o* of the accompanying tables; B will be a point of the curve. In the figure we suppose the radius of the curve to be a quarter of a mile, or 20 chains, and the tangent AA′, 5 chains. The table gives A′ B=63·5 links. From the point A, measure on the tangent AA′ a distance AB″ equal to the length found in the column *t* of the table, which is in the present case 2 chains 54 links, and through the points B″ and B (already found), draw the straight line B″ B B′, making B B′, which is a new tangent to the curve, equal to A A′, or any other convenient length; set off B′C at right angles to B B′, and equal to A′ B if B B′ was taken equal to A A′, otherwise equal to the length given in the column *o* under the length of tangent equal to BB′. C will be another point of the curve, and by proceeding in the same manner we can determine as many points as may be desired. By taking on any one of the tangents, such as A A′, a number of intermediate points, *a*, *a′*, *a″*, so that A*a*, A*a′*, A*a″* shall be equal to lengths of tangents given in the table, the corresponding offsets, *ab*, *a′b′*, *a″b″*, which are given in the column *o* under the respective lengths of tangents, will serve to determine as many intermediate points of the curve, *b*, *b′*, *b″*, situated between the points A and B. In the figure we have taken B B′ equal to A A′, or 5 chains, but the next tangent, C C′, for want of room, has been made only 3 chains long, so that the offset C′ D is only 22·5 links, as we find in the column *o* under the length of tangent 3 chains. The portions A*a*, BP and C*y* have been made each 2 chains, for which length of tangent we find the offset =10 links, and the other distances P*c*, P′*c′*, P″*c″*, &c. having been taken each equal to 1 chain, the tangents are 3 and 4 chains, and the offsets 22·6 and 40·4 links.

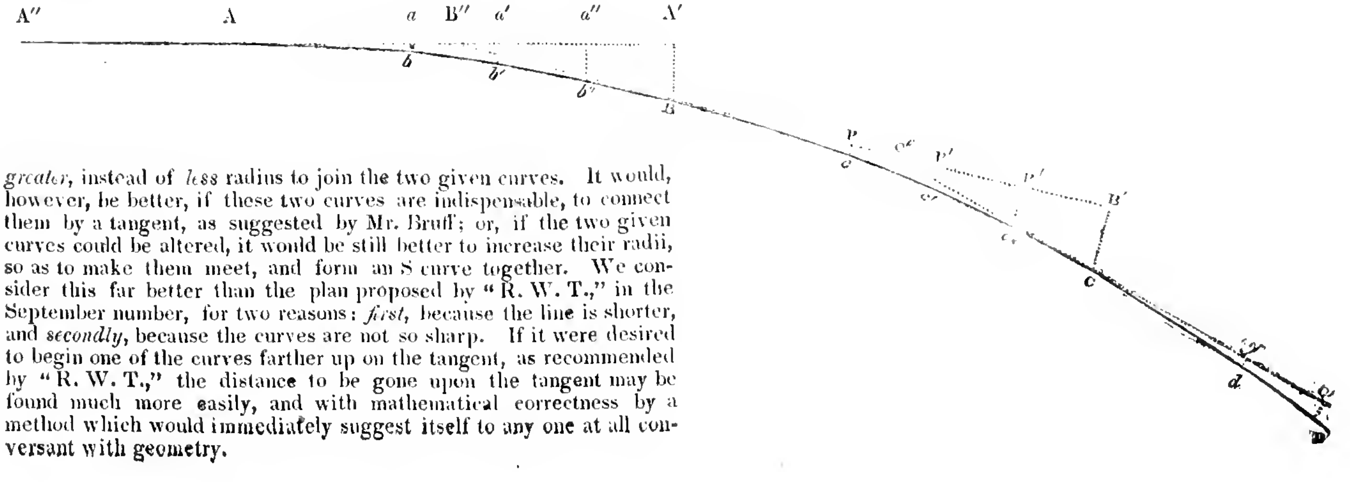


TABLE I.—CURVES FROM 5 CHAINS TO 80 CHAINS, OR ONE MILE RADIUS.

Radius of the Curve.	Length of the Tangent in Chains.

THE BUDE LIGHT.

In consequence of a statement in our Journal relative to an accident at Messrs. Hancock and Rixon's, Pall Mall East, caused by the explosion of a bag of oxygen gas, a correspondent of the *Times* sent to that paper a letter, of which we subjoin a copy.

TO THE EDITOR OF THE TIMES.

Sir,—In the new number of the *Civil Engineer and Architect's Journal*, there is an account of a fearful explosion of a bag of oxygen at the premises of Messrs. Hancock and Rixon, on the 7th ult., during some experiments on the Bude light. Everything in the room appears to have been shattered to pieces, one person flung into the shop window, another projected up a staircase, and all present more or less injured. The cause of all this seems involved in mystery. It is therefore important that publicity should be given to the affair, that it may be thoroughly investigated, particularly as it is proposed to adopt this light for the Houses of Parliament. It may be recollected by some of your readers that an explosion of oxygen occurred a few months ago at the Lowther Arcade, the cause of which was not satisfactorily stated, though it was conjectured to be owing to its being contained in a Mackintosh bag.

Pure oxygen is considered by chemists to be perfectly inexplosive and uninflammable. Faraday and Gurney have said this in their evidence on lighting the House; therefore some other gas must have been accidentally mixed with it; and what that gas was, and how it got there, it seems at the present moment particularly important to ascertain.

I remain, Sir,
Your's obediently,
J. R.

London,
December 2.

In reply to this the following letter appeared on the next day in the same paper, from Mr. Goldsworthy Gurney, the Inventor and Patentee of the "*Bude Light.*"

TO THE EDITOR OF THE TIMES.

Sir,—Your paper of this morning contains an exaggerated statement of a gas accident at Messrs. Hancock and Rixon's, said to have been occasioned by the explosion of oxygen, during some experiments on the Bude light. I beg most positively to state, that the accident so erroneously noticed was in no way caused by the Bude light, neither is the cause involved in any mystery, as your correspondent supposes; it was occasioned by common carburetted hydrogen gas. Oxygen used for the Bude light is not inflammable. Coal gas, oil gas, vapour of naptha, or other inflammable aeriform bodies, mixed in certain proportions with the atmosphere, which contains about a quarter part of oxygen, or pure oxygen, becomes explosive; in the Bude light no such mixture ever occurs. In those lamps in which an inflammable gas and oxygen are both used, they are never allowed to come in contact. In the Bude light at the House of Commons no inflammable gas of any description is employed, and explosion of any kind, therefore, as fully borne out by the evidence taken before the committee, is physically impossible.

I am, Sir,
Your obedient servant,
Goldsworthy Gurney.

London,
December 4.

It will be seen that Mr. Goldsworthy Gurney's is a flat contradiction of our statement, and we have consequently deemed it advisable to examine into the case more minutely and more critically than we otherwise should have done. Mr. Gurney might have been satisfied with our report, but as he has chosen to designate it an exaggerated one, and to state that the accident was in no way caused by the "Bude Light," we have to inform him that our statement was from an eye witness and sufferer by the accident, whom we have again consulted on the subject, and who positively states that it is in no wise "exaggerated," excepting that part which stated that one of the party was thrown "*into the shop window,*" it should have been *into the counting house*. The remainder of the statement he fully maintains, to be substantially correct; and we will now add a few more particulars to show Mr. Gurney that our information was obtained from a party present. So far are we from having exaggerated, it appears that we have underrated; one gentleman was stunned, and did not recover his senses for some minutes, another was so seriously bruised about the body that he was obliged to be taken to Dr. Stone in Spring Gardens—one of the Messrs. Rixons was also considerably injured—one of the persons had his thigh cut, and indeed the whole party were either more or less seriously injured. The damage done to the premises by the explosion was such, that a compensation has been paid to Messrs. Hancock and Co. by the Insurance Company.

We understand from one of the party that to the best of his recollection the accident occurred in the following manner:—A bag was lying on the floor containing oxygen gas, to which was attached a flexible tube: as the attendant was about to apply the tube to the lighted lamp, he heard some one say "Now put on the weight," but at the instant the tube was being applied to the light, the accident took place, as described by us last month. By the explosion, the bag, which was made of Macintosh's prepared cloth, was completely rent into pieces.

We have also seen some of the other parties who were present, and they all confirm our report of the accident, excepting as to the before mentioned error, that one of the party had been forced into the shop window. The whole affair is so unsatisfactory that we must certainly express our mistrust as to even the alleged causes of the accident.

We shall now give a letter addressed to us by Messrs. Hancock and Co., in which the accident is attributed to carburetted hydrogen.

TO THE EDITOR OF THE CIVIL ENGINEER'S JOURNAL.

Sir,—We beg the favour of your inserting the following statement in your Journal, in reply to the exaggerated and incorrect account of the explosion which took place upon our premises, and which appeared in the last month's number, the cause of which was unwarrantably cast upon the Bude light.

The facts are these: a bag of oxygen gas was sent to us, which had previously been used for carburetted hydrogen, and which had not all been emptied out when the oxygen was put in, there being sufficient hydrogen left in the bag to render it an explosive mixture.

The Bude light can only be produced by pure oxygen, which every one knows is not explosive; and we hope that any stigma that may have been cast upon the Bude light by being the attributed cause of the accident, will now be removed.

We are, Sir,
Your most obedient servants,
Hancock, Rixon & Dunt.

After a careful perusal of this letter, can the public be satisfied without having a strict enquiry made into the whole affair? Public safety is too seriously threatened to be thus trifled with. We should like to know how this bag came to be used previously for the purpose of holding Hydrogen Gas,—for we are very fearful that Messrs. Hancock and Co. have been misled upon the subject—witnesses ought to be brought forward who filled the bag with the carburetted hydrogen previously, and to state for what purpose it had been used, and the quantity that was likely to have been left in the bag—at any rate it is undoubtedly a fact that oxygen gas is highly explosive, if it be slightly contaminated with carburetted hydrogen, the same as gunpowder would be if a spark were applied.

Having laid before our readers the above particulars, we will leave it to them to judge whether we are liable to be impugned for the accuracy of our statement. Our own impressions are justified both as to the propriety of demanding an enquiry then, and as to the necessity of its being made now. We entertain no ill will towards Mr. Gurney, but we are bound to justify to the public any attacks upon our editorial character, at the same time that it is our duty to protect the public interests.

ON THE ADHESION OF THE WHEELS OF LOCOMOTIVE ENGINES, by W. R. Casey, C. E., *of the United States.*

[We are indebted for the following communication to the kindness of its able author, by whom it was prepared for the *American Railroad Journal.*]

Powerful locomotive engines will seldom be required for passenger-trains, and, up to this time, the quantity of freight carried over any railroad in the Union, as far as I can ascertain, falls short of 100,000 tons per annum, whilst the average, according to De Gerstner, is only 15,000 tons, carried over each railroad in the country. This is about the one hundredth part of what can very well be done on a well located railway with a single track.

We may however confidently expect that railways will very soon be used for the transportation of freight on a scale sufficiently extensive to prove their capacity for this object. As yet there can be little danger in asserting, that there is not a railroad in the country, which has been located, constructed, and subsequently managed, so as to be even tolerably well adapted to the transportation of a large quantity of freight. The Reading railway will be first in the field to show the power of this new means of communication, and it would be difficult to find a better champion for the cause of railroads. On the Reading road there is, however, no ascending grade in the direction of the greatest trade, and the common 8 or 9 tons engine will easily draw 150 to 200 tons on a level—the greatest resistance offered with the admirable grades of that road; but, where inclinations of from 40 to 60 feet per mile are to be surmounted, engines of that weight are utterly inadequate to the task, whilst heavier or more powerful ones require a more substantial and consequently more costly superstructure.

The question then naturally suggests itself—cannot the power of the engine be increased without an increase of weight? which again immediately leads us to consider, what it is which limits the power of the locomotive steam engine. This is well known to be the friction, or, as it is generally termed, "the adhesion" of the wheel to the rail which all good engines built during the last 4 or 5 years have been able to overcome; that is, where the load was sufficiently great, to make the driving wheels revolve without causing the engine to advance. Strange as it may appear, no experiments have yet been made to determine this all important point, and the "friction of iron on iron" given in treatises on mechanics, as equal to about one-fourth of the weight, has been hitherto used in all *calculations* as the maximum, though numerous well authenticated *performances* have shown, that the ratio of the adhesion to the weight must have been much greater than this. In a pamphlet written so late as year 1838 Messrs. Knight and Latrobe, speaking of a performance of the Stonington locomotive, which showed the adhesion to be equal to $\frac{1}{4\cdot33}$ of the weight, say "As this is greater than we have known in any other case, it is presumed that a portion of the weight of the tender was tranferred to the engine, &c.; but performances of the engines of Baldwin and Norris on the Philadelphia and Columbia railway, long before this pamphlet appeared, go very far beyond this.

In 1836, engines built by Mr. Norris, not exceeding 8 tons in weight, drew loads equal to 400 tons on a level, which, if the weight on the driving wheels was correctly given, showed the adhesion to exceed one-third of the weight. Mr. Baldwin's engines have, however, since exceeded even this, and have drawn loads equal to above 700 tons on a level. Estimating the traction at 10 pounds per ton, this will require a force of 7000 pounds, and the weight on the driving wheels of Mr. Baldwin's first class engines being stated at 12,120 pounds, the adhesion must have been equal to $\frac{1}{1\cdot73}$ of the weight, if this did not exceed 12,120 lbs. or even adding 4000 pounds for the tender, equal to $\frac{1}{2\cdot3}$ of the insistent weight.

After making every reasonable deduction, it appears beyond all doubt, that the adhesion has been very much underrated, and, though this alone keeps the power of locomotives within their present range, I have never heard of a single direct experiment to determine this important law. In the edition of 1831 of Wood on railroads the adhesion is stated at one-twelfth, subsequently it is assumed by Mr. Knight at one-eighth, or "half the friction of iron on iron," which value was not determined by experiment but was merely deduced from the load; so again in the pamphlet already referred to, as late as last year, $\frac{1}{4\cdot33}$ is "greater than we have known in any other case."

Since writing the above, I have seen the experiments of Mr. Rennie on friction, as detailed in the 5th vol. of the Journal of the Franklin Institute, 1830, and he there shows, that there *is* an increase in the ratio with the increase of weight, the surfaces in contact remaining he same. The extreme weights in 11 experiments, [p. 9,] are 1·66 cwt. and 5 cwt. per square inch, and with these pressures, the ratios of the weights to the adhesion are respectively as 4 and 2·14 to 1. The results of the experiments are very irregular, and though in this particular case the ratio varies very nearly as the square roots of the weights, there is nothing to point out the law of increase, so as to enable us to continue the table with any confidence.

On the next page [10] it is stated that with 6·5 cwt. per square inch, cast and wrought iron abrade, and the friction is to the weight as 1 to 2·3. Now, as the weight on the driving wheels is generally 2½ tons on each, as the friction of wrought iron on wrought iron is greater than on cast iron, as this difference is rendered the greatest possible by the parallelism of the fibres of the tire and rail, and as the surfaces in contact can scarcely be one-fourth of a square inch, it is evident, that the power required to produce motion, when the pressure is 2½ tons on a surface of much less than 1 inch square, must be more than $\frac{1}{2\cdot30}$ of the insistent weight. It is stated, [p. 10,] that hardened steel abraded with 10 tons per square inch, but the ratio of the power to the weight is not given.

The laws of friction, are however, only applicable as long as no abrasion takes place, and this falls very far short of the case under consideration, where the pressure is often sufficient to cause even hardened steel to abrade. Still these experiments and numerous performances of the engines of Baldwin or Norris would lead to the conclusion, that the adhesion is at least twice as great as that which Messrs. Knight and Latrobe designate as "greater than we have known in any other case."

"The most interesting performances of locomotives which have fallen under my observation are those detailed in the Franklin Journal of June 1839, where an engine on 8 wheels, constructed by Messrs. Eastwick and Harrison, *started*, on a grade of 27 feet per mile, a load of 265 tons, subsequently overcoming with the same load, a rise of 35 feet per mile. This took place on the bad and crooked road between Broad-street and the Schuylkill-bridge, where the traction must have been 10 pounds per ton on a level, and the entire force exerted by the engine equal to 6600 pounds. In this engine there are *four* driving wheels, on which the weight was 18,059 pounds, showing thus, that the adhesion was equal to one-third of the weight even *with the wheels coupled*. The weight on the driving wheels of Baldwin's engines of the first class, is one-third greater than on *one* pair of driving wheels of the engines of Messrs. E. and H., and any sudden lurch of the engine which, with the ordinary construction, will throw more than half its entire weight on one wheel, will, with these engines, be distributed on two wheels, and there can be little doubt, that an engine with the usual weight on 2 driving wheels, will be more injurious than one with twice that weight on four drivers, as arranged by Messrs. E. and H. Here is an engine which will with ease, draw 100 tons nett, up an ascent of 60 feet per mile, and which requires, on *that* inclination, a superstructure no more substantial than is required by the lightest engines of Baldwin or Norris, on roads varying from a level to 20 or 30 feet per mile—*and this too with anthracite fuel*.

In the interesting pamphlets of Messrs. Knight and Latrobe, already referred to, those gentlemen state that the Camden and Amboy Company "is now building, and have nearly completed, an engine upon 8 wheels, and having two cylinders of 18 inches diameter by a 3 feet stroke; the whole supposed to weigh 18 tons." * * * * "The adhesion upon the rails of all the 8 wheels, is to be brought into action by means of cog-wheels, &c." * * * * "This engine is designed to lead burthen trains at moderate rates of speed; but must be viewed as yet in the light of an experiment."

It is difficult to conceive how such, in other respects, keen observers could pass by with cool indifference the most striking fact related in either of their interesting pamphlets, and which, even without being completely successful, would be attended with results infinitely more important than the benefits resulting from all American improvements in railroads and locomotives united. In illustration, not explanation, it may be proper to observe, that of all the engineers and machinists with whom I have conversed for the last two or three years on this subject, I have only found two engineers [the machinists would not listen to it] who had given the subject that serious attention to which it is, in my humble opinion, pre-eminently entitled. One of these gentlemen, Mr. H. R. Campbell of Philadelphia, showed me, nearly three years since an engine on 8 wheels and 4 drivers, which he was then building to burn anthracite coal, and which certainly bore an astonishing resemblance to the drawings of Messrs. Eastwick and Harrison's engine in the Franklin Journal, and to the advantages of which I have already alluded.

We have seen that with the 8 wheeled engine and 4 wheels coupled, the adhesion was equal to one-third of the weight on the propelling wheels, and if, with the 18 tons engine of Messrs. Stevens, we suppose the adhesion equal to only one-fourth of the weight, we shall have a machine capable of drawing 1000 tons on a level, without greater injury to the superstructure than the ordinary 8 or 9 tons engines of Philadelphia, Baltimore, New York, Lowell, &c. An 8 wheeled engine, weighing 10 tons, acting by the adhesion of its entire weight distributed equally on the 8 wheels, will draw 90 tons nett up an ascent of 60 feet per mile, and there will be no inducement to lessen this weight, as it is only 1¼ tons per wheel, or the same as that on each wheel of an ordinary freight or passenger car, when loaded.

It is well known, that the rapid destruction of wooden rails is not caused so much by the natural decay of the timber consequent on its exposed situation, as by the crushing under the driving wheels of the locomotive, which destroys the lateral cohesion of the fibres of the wood and admits water, the grand agent of decomposition. Notwithstanding this disadvantage, the repairs of the wooden track of the Utica and Schenectady railroad, do not exceed the repairs of the best roads about Boston, (from 300 to 350 dollars per mile per annum, the renewal of the iron being neglected in both cases) and if an engine of 10 tons will not be more injurious to the superstructure, than an ordinary car, it may yet appear, that this improvement *alone*, will reduce the repairs and renewals of the common superstructure, below those of the best road in the Union, omitting the assistance which may reasonably be expected from Kyan's, or some other mode of preserving timber.

It has frequently happened, that horse power has been used for a short time after the opening of a road, by which the nice adjustment of the rails as received from the hands of the engineers, has been little if at all affected. After the road has been travelled by the engine, however, even for a single week, with the very same cars, depressions and inequalities will be found greater, as well as more numerous than those which would be produced by the action of the *cars* only in six months or more. Timber as well as iron will bear a certain strain without the least injury, but a slight increase beyond this, produces a permanent set or deflection, hence, in reducing the weight from 2½ to 1¼ tons per wheel, the relative strength of the superstructure is not merely doubled, but is increased in a much greater ratio. This proportion will be affected by the dimensions of iron and timber, kind of wood, arrangement of parts, nature of earth, &c., but as a general rule it will be greatest where most needed—for instance, when a light superstructure is bedded in clay, in a northern climate.

The distribution of the weight of the engine on 8 wheels, instead of throwing three-fifths or more on 2 wheels, is therefore intimately connected with the continuance of a cheap superstructure, which has been, one will be, even with the present engines, extensively used in many parts of the country, where capital and good mechanics are scarce and timber and axe-men abundant. Owing to the increased deflection of the wooden rail there will of course be a loss of power, but this, even now not very important, will be reduced one-half by the distribution of the weight on all the wheels, besides which the only fear is, that full loads will only too seldom be obtained for the lightest class of engines, built on this principle, even with grades of from 40 to 60 feet per mile.

I have been informed by my friend Mr. E. F. Johnson, (the other engineer alluded to in a preceding paragraph) that a trial of this new engine has been made, and that it appears to work well. Time and experience can however alone develop its powers, expose its defects and give unerring proof of its general and successful adoption. But supposing, what is most unlikely, that this experiment should lead to no useful result, we have still the 8 wheeled engine of Messrs. Eastwick and Harrison (or Mr. H. R. Campbell?) which is capable of drawing 100 tons nett up an inclination of 60 feet per mile, and which will be less injurious to the superstructure than the ordinary 8 or 9 tons English or American engine.

An extremely interesting and still more useful experiment may very easily be made with the engine of Messrs. E. & H., or still better, with that of the Messrs. Stevens. Remove the couplings so that the engine may act by the adhesion of one pair of wheels only, and ascertain the maximum load without slipping the wheels; then couple 2 pair of wheels, repeat the experiment and the increase of load will show the value of the improvement of Messrs. E. & H. With the 8 wheeled engine, 4 such experiments should be made, by which the advantages of this mode of construction would be determined with considerable accuracy, and all requisite information afforded on this vital, and hitherto much neglected principle, of working by the adhesion of more than 2 wheels.

The successful introduction of engines with the weight distributed equally on, and acting by the adhesion of 8 wheels, would form an era in the history of railways in the United States, second only, to that which determined the general question of the practicability of locomotion by steam—in other words, that which gave its present importance to this unrivalled mode of communication.

ON THE DRAUGHT OF CARRIAGES AND ON SECONDARY FRICTION. By M. DUPUIT, C. E.

(Translated from the French.)

1. DRAUGHT OF CARRIAGES.

By allowing wheels of diameters varying from 4 feet to 7 feet to run down an inclined plane, and by measuring the spaces run over on horizontal ground, by virtue of the fall, we find that they are proportional to the square roots of the diameters, and height of the fall, whatever may be the weight or breadth of the tire. From this we derive the four following laws:—

The draught is proportionable to the pressure;
independent of the breadth of the tire;
independent of velocity;
in inverse ratio of the square root of the diameter.

These four laws are the same as established by the author of this paper in his Essay on the Draught of Carriages, published in 1837, and which he had found by means of a simple dynamometer. The three last are completely in contradiction to those which M. Morin deduced from the experiments made with his dynamometrical apparatus.

2. SECONDARY FRICTION OF ROLLING.

The resistance which opposes the rolling of a body is nothing more than the molecular action, which takes place on contact. This reaction, always equal to the pressure, passes by the normal when the body is at rest, and advances in front by a certain quantity δ when it rolls; it therefore resists the rolling with a power marked $P\delta$.

Following up this single property of solid bodies, of being an assemblage of molecules in equilibrium, we arrive at the following expression of the friction of rolling:

$$T = \frac{P}{\sqrt{2R}} F\left(\frac{P}{a L \sqrt{2R}}\right),$$

which gives all the properties of this resistance in friction with one of them. If we follow up that of being proportional to the pressure, which is not denied by any one, we rediscover the three other laws pointed out above, which establishes a mutual confirmation of the experiments and the theory. The friction of rolling being an immediate consequence of the imperfect elasticity of bodies, we may, by its properties, ascertain those of elasticity; whence we deduce the following:—

When we subject the surface of a body to pressure, we obtain under this pressure a certain instantaneous sinking e', which reduces itself at last to a slight impression e, when the pressure ceases. This impression e is proportional to the square root of the definitive sinking e'. The friction of rolling is proportional in the relation of $\frac{e}{\sqrt{e'}}$, in such a way that it is determined by two coefficients which define the elasticity of a body. For want of these two coefficients we may substitute two others. Knowing 1st, The friction of iron upon iron, and of iron upon marble, we may deduce immediately from it the friction of iron upon copper. Thus for twenty surfaces, forty coefficients would be enough to determine 380 to which their combinations two by two would give rise.

When two curved surfaces roll one upon another, the result of the molecular action, equal to the pressure, no longer passes in the direction of the normals, but parallel in the direction of the velocity, at a distance, proportionable to the square root of the product of the rays or radii of curve, divided by their sum or difference, accordingly as they are both convex or one of them concave.

This formula resolves all the problems relating to the calculation of the resistance to rolling, and it is capable of numerous practical applications.

3. ACTION OF WHEELS UPON ROADS.

Although the draught is to a certain point the expression of the derangement of the materials of the road, it is quite inaccurate to conclude therefrom that the degradation is proportional to the draught. By keeping the roads constantly even, which is always possible, the passages are divided uniformly on the whole pavement;* then the small displacements which they occasion destroy each other. Besides in a number of cases the result of the passage of a carriage is to produce an improvement. In a good system of road making, the roads are never degraded, whatever may be the traffic, they are only worn. It cannot be a question, in a road law, of having good or bad roads, but only of spending more or less for their maintenance. Every restriction of the freedom of a road is to the carriers a cause of increased expence, greater than the saving which might be made in the expences of keeping up the roads.

PAPERS ON ARTESIAN WELLS.

Observations undertaken for the purpose of estimating the height to which the Water might rise in the Well bored in the Abattoir de Grenelle, by M. WALFERDIN. *Read before the Academie des Sciences.*

The water which springs up from Artesian sources does not always rise above the level of the soil, sometimes it is several yards lower, and in this case it is brought to the surface by mechanical means; sometimes it reaches it; and at other times it rises more or less above the surface. That as it is well known depends upon the difference of height at which the water arrives across permeable strata, between the impermeable strata which contain it, and that of the point at which they ascend.

I have considered that in the advanced state of the borings at Grenelle, that it might be useful to compare the height at which are filtered the waters which form the supply which is sought under the Paris basin, and that of the surface of the soil at Grenelle.

If, by ascending the natural slope which the waters follow to the surface of the earth, we seek the chalk boundary in the southwest direction, we find it cease in the neighbourhood of Troyes. Then the gault marls and clays which the bore now crosses at Grenelle succeed the chalk, and at about eleven miles from Troyes, near Lusigny, the green sand appears, and forms the orifices by which the waters begin to filter.

The height at which the waters thus penetrate the sands being near Lusigny, 135 or 140 yards above the level of the sea, and that of the surface at Grenelle 40 yards only, it follows that when the bore reaches the layer of water at Paris, that the water will rise sensibly above the surface.

* It must be remembered that M. Dupuit is talking of French roads.—ED.

CALCULATING BALANCE FOR ENGINEERS.

BY M. LEO LALANNE, C. E.

(Translated from the French.)

It is often necessary to multiply by each other the terms of two series, and to divide the sum of the products by the sum of one of the series. This calculation, which gives a kind of mean, is that used to find the centre of gravity, to determine certain probabilities, and to solve various questions, which occur in all the mathematical and physical sciences. M. Lalanne has conceived the idea of performing this operation by means of a kind of Roman balance loaded with different weights, and on which the quotients required can be read off on a scale, and obtained with that degree of approximation which allows the representations of numbers by distances and weights.

The plan of this machine is formed on the following considerations:—If we distribute on one of the arms of a balance weight, which are proportional to the terms of a series, and if we place them at distances from the point of suspension, which represent the terms of a second series, if on the second arm of the balance we suspend an equal weight to the sum of the weights already placed on the first arm, it is clear that the distance at which this total weight must be made to act for the equilibrium, will be the sum of the products of the opposed weights, multiplied respectively by their distances from the axis, and divided by the sum of the weights. So much the more exactness will be obtained in this result if the weights and distances are more exactly proportional to the terms of the two series which are to be operated upon, and as the balance is made more sensible.

M. Lalanne intends his instrument principally to assist engineers in calculating the mean distances of transports. We know that in these calculations we must take the sum of the products of the cubes to be transported by the distances which correspond to them, and divide the sum of these products by the total cube. If, then, we take weights which represent partial cubes, and if we place them on one of the arms of the balance, at distances which represent those of the transports; if, at the same time, we place a partial weight on one side of the balance, an equal one is placed in a scale suspended from a very precise point of the other arm, and this point may be moved about until equilibrium is effected, its distance from the axis of suspension will represent the mean distance sought.

In M. Lalanne's balance, the upper part of the beam is divided into 150 compartments, each two millimetres broad; upon it are placed the weights—the distances thus taken from a hundred and fiftieth part nearly up to 600 metres. The volumes are represented by the weight, a cubic metre answering to five milligrammes, a total of 20,000 cubic metres, may easily be operated upon with the approximation of one of these units.

An experiment was made on the comparative duration of the times necessary to obtain a mean by this instrument, and also by ordinary arithmetical calculation—a calculation which required fifty minutes to execute once without verification, was done by the machine in twenty minutes, with only the chance of a very slight error. Thus the time necessary is reduced at least by two fifths, giving besides a security against great errors, and it would be reduced to a quarter if the ordinary arithmetical calculations had been verified. Although the instrument can only give an approximation, and as in all graphic operations, we have not the exact figure of the result, nevertheless the saving of time is great enough to show the utility of it to engineers.

BALISTIC CLOCKS,

FOR ASCERTAINING THE POWER OF GUNPOWDER.

(Translated from the French.)

These clocks were constructed in 1836, in the Arsenal of Metz, the Woolwich of France, by Messieurs Piobert and Morin, and from the nature of the experiments made with them, were formed so as to fulfil the following conditions:—

1st The suspension of the cannon clock must be susceptible of receiving easily and at little expense, cannons and howitzers of every calibre.

2nd The machine must be sufficiently light for its susceptibility to be great enough for small calibres, and small charges, and nevertheless the recoils must not exceed certain limits in heavy charges.

3rd The balistic receiver must be susceptible of receiving without injury, the shock of projectiles of all calibres, propelled with the greatest speed that powder can communicate to them, and be entirely constructed of metal to avoid the effects of hygrometricity and the corrections which it necessitates for wooden clocks.

4th The mechanical requisite of having the centres of oscillation on the line of fire being absolutely necessary for all calibres, required easy means of effecting it.

The detailed reasons which led the inventors to adopt forms almost totally different from those of the old productions of Hutton, and those which had been established at the powder factory of Esquerdes, have been already published by them.

From a summary description of the apparatus, M. Morin shows, by the results of experiments conducted by Captain Didion, Professor at the School of Application at Metz, how great is the accuracy of these instruments. Thus, in the fire of a sixteen-pounder, (about eighteen English,) loaded with a charge of 4lb. 6oz., of four shots fired with charges prepared with care, the speed given to the ball did not differ more than 2 feet 7in, $\frac{1}{510}$ of its mean value, 482·7 metres.

Among other remarkable experiments, these instruments have been used by M. Didion to determine in an accurate manner the charge of powder, beyond which the velocity ceases to increase in 12-pounders (French), and which more than 17½lb., that is to say, much more than the weight of the ball.

Besides, this extraordinary fire, the same apparatus has been used to measure results much superior, since by their means have been ascertained velocities of 660 metres in a second, communicated by particular powder to a 24 pounder shot.

In fine, by firing with a 12-pounder garrison gun, common shells of 12 inch calibre, weighing 4.010 kil., with a charge of 6 kil., they obtained a velocity of 745·3metres in a second, which is the greatest that man has ever yet been able to communicate to moveable bodies.

The machines have satisfactorily answered the purposes for which they were intended, so that the Minister of War has had others made, which have just been set up at the powder works of Bouchet, near Arpajon, and he has ordered a third set for that of Toulouse.

In conclusion, the principle, and general arrangement, of these clocks has been applied by M. Morin to the construction of a wooden clock, of which the receiver closed with a wooden barrel, five feet diameter, will receive the shock of a projectile fired at variable distances of 50, 100, or 150 yards to determine the effects of the resistance of the air. These experiments are already in course of operation by Captain Didion, at Metz, and they afford positive data, and the bases of experimental balistics, so necessary for artillery practice.

PENZANCE HARBOUR.

Extracts from the Report on the improvement of the Harbour of Penzance, by HENRY R. PALMER, F.R.S.

GENTLEMEN,—In obedience to the instruction of the Town Council, given to me through George D. John, Esq., the Town Clerk, I have endeavoured, as far as lay in my power, to acquaint myself with all those circumstances on which the improvement of your harbour depends; and by a careful consideration of them to prepare such suggestions as I trust may be conformable with your wishes.

The principal observations which I collected referred to an undulatory motion of the water which is invariably felt when the wind is high, and to an occasional "lifting" of the waters arising from distant causes.

The undulating motion of the water is experienced at the extremities of all bays, the beds of which form a gradual slope towards the shore, like that which is under consideration, and the effect can only be reduced by an alteration in the form of the surface, and by a protection from the action of the winds.

It being obvious that the improvement of the harbour must consist mainly in the erection of an additional pier, I was anxious to have the opinions of the nautical men as to the best situation and form of the entrance; and, also, upon the width of the opening. Upon the situation of the entrance southward and northward, there was no important difference of opinion; but it was thought advisable to advance the entrance, if practicable, into deeper water than that at the head of the present pier. The relative positions of the pier head were discussed at some length; and there was a manifest difference of opinion on that point. It is, indeed, one on which it is very difficult to decide *à priori*. I am not acquainted with more than one pier harbour, the entrance to which was so designed originally as to be in all respects satisfactory when carried into effect; and in laying down the plan, which I have now the honour to submit to the council, I have thought it prudent so to arrange the position of the pier heads, as to admit of their being finally adjusted as experience acquired in the progress of the work may dictate.

For the satisfaction of the council, I have deemed it advisable to lay before them plans of other pier harbours. By help of these, some comparisons may be formed with that proposed for Penzance, not only in relation to their extent, but also to their security. They are as follow:—

Ramsgate—Dover—Folkestone—Swansea.

The harbour of Ramsgate is entirely artificial; and is constructed on a shore directly opposed to the prevailing winds. Its security is therefore exclusively derived from the piers by which it is enclosed. The width of the entrance was originally 300 feet, and open due south. The exposure to vessels moored in the harbour, was such as to induce the necessity for an additional protection; and the eastern pier was extended as shown in the drawing, and the width of the entrance reduced to 200 feet exposed directly to the south west, or the most prevalent winds. From this circumstance it may be readily inferred, that, during gales from the quarter last mentioned, Ramsgate harbour offers but little security.

Dover harbour is less exposed than that of Ramsgate, but it is frequently rendered inaccessible by the accumulation of shingle, of which the beach is composed. The direction and position of the piers, which define the entrance to Dover harbour, have been, for the most part, designed with a view to avoid the difficulties arising from the accumulation of the shingle, rather than as a protection against the effect of the winds. The entrance is 150 feet in width, and is open near due S.E.

Folkestone harbour has advantages over all the others on the same coast, in reference to its position. It is the most easily accessible, and is well protected against the effect of the south-westerly winds. It is, however, rendered very imperfect, and the entrance to it sometimes impracticable by the same causes, which so much deteriorated the value of Dover harbour. It is frequently necessary to remove the shingle from the mouth of it by manual labour. But, in other respects, the position of the entrance in relation to the prevailing wind is very favourable. The mouth faces the S.E.E., and is 100 feet in width.

Swansea harbour is the most extensive artificial harbour on the British coast. It is situated in the Bay of Swansea; and has the advantage of a river flowing through it, by which a considerable portion of the bed is cleansed, and its depth preserved. The mouth is 300 feet in width, and is exposed nearly due S.W. The slope of the bed is such as to occasion a considerable ground swell when the wind is strong from the prevailing quarter.

The chief quality of the entrance to Folkestone harbour is derived from the angles of the line of its mouth with that of the prevailing winds. The angle is about 39 degrees, which forms an angle 210 degrees with the line of action of the wind referred to.

The wind against which the most protection is required at Penzance is S.S.E. The angle of the line of entrance as drawn in the plan is 45 degrees with that bearing, or 200 degrees with the line of force. As before observed, the positions of the pier heads are so arranged, that that angle may be increased, if by experience the necessity for so doing may be evinced.

With reference to the width of the entrance of the intended harbour, the same latitude will be preserved as with the direction of it, for it is impossible to determine beforehand with certainty, what width will, under all the circumstances, be most advantageous. In the first place I have assumed 175 feet.

Having adverted to the first and most important point to be decided, I have now to describe the general design for the harbour.

In the first place, I have endeavoured to include as great an area of ground as possible within the limits of the property of the corporation. The northern pier is drawn near about the line of low water of spring tides. Its direction forms an angle of 20 degrees with that of the S.S.E. wind.—The capability of the pier to resist the action of the sea is therefore satisfactory. The surface of the pier is proposed to be 30 feet in width, exclusive of the parapet wall. The pier is proposed to terminate at the northern extremity of the town property.

The pier is proposed to be constructed with granite, and the interior between the walls to be filled with the stones obtained by the excavation in the harbour. A considerable length of the northern portion of the pier need not be walled in the substantial manner required where it is more exposed, and in deeper water. Rubble work, laid with a long slope on the face in the part referred to, will not only be more economical, but will also form a better termination than a perpendicular wall, in as much as it will gradually divert and disperse the action of the sea.

It being the opinion of many of the nautical men that some advantage would be derived by the extension of the southern pier; and considering that the extremity of it may require repair and support, I have proposed an addition to it of 50 feet.

It may be proper here to remark that although I have included by the proposed pier the greatest area available within the limits of the corporation property, the pier as designed will cost a less sum than would have been requisite for a more limited inclosure in the northern direction.

The whole area thus to be enclosed will exceed 40 acres; and there can be no doubt that such a work alone would be one of great value and importance; but still it would be deficient by the total recession of the tidal water from it. The area, however, is such as to allow of a portion being abstracted from it for the purpose of a floating dock. In the plan I have represented a portion so abstracted to the extent of ten acres, a communication being made between the harbour and the dock, by means of a lock, capable of passing vessels of 500 tons burthen.

The division wall is represented near to a lane called Neddy Bettey's Lane. The lock is so placed as to enable vessels to be passed through conveniently and with safety.

It is proposed to form a quay along the boundary of the dock, which will admit of the erection of warehouses, which being built upon arches, will not prevent the traffic of carriages along the quays.

I have not laid down any design for a quay along the front of the town, but, have represented by a dotted line what I conceive should be the limits of a quay if such should hereafter be decided upon.

At the southern extremity of the harbour I have represented a boundary line, including a space which appears to me to be peculiarly suited for a ship yard, in as much as it will be a convenient situation for launching.

In considering the various circumstances affecting the general design, I have had especial reference to the practicable operation of executing it.—This is peculiarly important, where the work is exposed in its progress to the violent action of the sea; and I have no hesitation in stating distinctly that for the execution of the work, with due regard to economy, and to avoid damage to it by the sea whilst it advances, it will be necessary to commence at the northern extremity, and proceed regularly, making all its parts perfect as they are severally produced.

This view of the case constitutes an additional, if not alone a sufficient argument in favour of continuing the sea wall to the point mentioned.

In conclusion, I must beg permission to state that the shortness of the time within which it has been necessary for me to furnish my plan and report has not been permitted me to obtain and furnish them in so complete a state as they should have been presented in.

Certain sections, soundings, and measurements, are necessary, and yet wanting, and, indeed, before the subject can be continued beyond what is necessary for the Parliamentary proceedings, a complete survey made for the particular objects in view will be indispensable; and it will be equally important to obtain a series of observations upon the tides, about which I have not yet been able to collect any precise or valuable information.

In forming an estimate of the expence of the works, I have been obliged, from the absence of sufficient accurate data, to assume a larger consumption of materials than I believe will be required, in order that the error may be on the safe side; and hence, I can, with confidence, state that the sums annexed will be more than sufficient for the execution of the works proposed.

ESTIMATE OF EXPENCE.

Erecting a northern pier, as represented in the drawing. Making an addition of 50 feet to the present pier; and thus constituting a safe and commodious harbour	£24,000
Erecting a cross wall for the construction of a floating dock of ten acres in area, with a ship lock, and tide gates, and swivel bridge, and forming quays along the boundary of the dock	8,500
Parliamentary and law expenses, engineering, &c., say	2,500
	£35,000

ROYAL SOCIETY.—THE PRESIDENT'S ADDRESS.

THE following is the address of the President (the Marquis of Northampton), at the meeting of the Society on the 5th ultimo.

GENTLEMEN—A year having now elasped since you conferred upon me the highly honourable office of your President, it becomes my duty, in accordance with the example of my predecessors, to address you. The first and most agreeable part of my task is to express my feelings of gratitude to those Gentlemen whom you were pleased to select as my Council. * *

The past year has indeed been to that portion of the Royal Society which takes an active part in its affairs, one of more than usual labour and exertion,—of labour and exertion, destined, as I hope, to produce rich and ample fruit. The great and marking peculiarity which has attended it, has been the sailing of the Antarctic Expedition. The importance of following up in the southern regions of the globe the magnetic inquiries so interesting to men of science in Europe, was strongly felt by one of our distinguished Fellows, Major Sabine, and by him brought before the notice of the British Association at their meeting at Newcastle, as he had also previously done at Dublin. That great assemblage of men of science, concurring in the views of Major Sabine, resolved to suggest to Her Majesty's Government the propriety of sending out a scientific expedition; and the Royal Society lost no time in warmly and zealously seconding the recommendation: and, in compliance with the request conveyed to us by the First Lord of the Admiralty, the Council transmitted to the Government a body of hints and instructions in different branches of science, which I trust are likely to be of material use both to the principal and to the subsidiary objects of the Antarctic Expedition. These hints and instructions would have been far less extensive and efficient if the Council had not been able to have recourse to the several Scientific Committees, of whose formation the Society is already aware. The Expedition has now sailed, amply provided with the best scientific instruments, and furnished with ample scientific instructions: it is commanded by one well acquainted both with magnetic inquiry and nautical research. We may therefore hope that, with the blessing of Providence, it will return with a store of knowledge valuable to the geographer, to the geologist, to the meteorologist, and to him also who studies the marvels of vegetable and animal life. In addition to all this we may hope, that the main object of the Expedition will be accomplished by additional light thrown on the obscure problems which still attend the magnetism of the earth, and that by such discoveries Captain James Clark Ross may not only add to his own reputation and his country's glory, but also give to the adventurous mariner increased facility and security in traversing the pathways of the ocean. The Antarctic Expedition was not the only measure recommended by the Royal Society and the British Association to Her Majesty's Government. Another important recommendation, which had previously been brought forward by Baron Humboldt, was the establishment of fixed magnetic observatories for the purpose of making simultaneous observations in different parts of our colonial possessions. These recommendations have been readily acceded to, both by the Government and by the Directors of the East India Company, and probably, ere many months shall have elapsed, the observatories will be in full activity.

I have stated, Gentlemen, that your Council had recourse to the Scientific Committees for assistance in drawing up instructions for the Expedition in different branches of knowledge; those committees, who were named only two years ago, were at first apparently more a matter of form than substance; they have now been found capable of doing excellent service. Not only has your Council consulted them on the questions already alluded to, but also, observing that the several Committees are composed of the most competent judges of the merits of the memoirs in the respective departments of science communicated to the Society, they have, in general, referred the papers to them to report upon previously to coming to a decision regarding their publication. The Royal Society, from its character of pursuing every branch of physical science, is evidently in a different position from other societies professing some one science alone. It may be reasonably expected, that in the Botanical or Geological Society, for instance, the whole Council should possess a certain degree of botanical or geological knowledge. This, however, cannot be the case with us. Our Council will comprise a few astronomers, a few zoologists, a few botanists, and a few persons well acquainted with geology and medicine; but no single science can monopolize a large number of its members. In difficult questions we have therefore felt that it is more satisfactory to ourselves, and we think probably more so to the general body of the society, and to those who have favoured us with papers, that we should ask the opinion of a larger number of men conversant with the immediate sciences in question. At the same time, the Council retains its responsibility for its acts, and the chief officers of the society are officially members of each of the scientific committees. The Council have derived a further assistance from these Committees in the adjudication of our medals. In naming these Committees, the Council has had both a difficult and a delicate task. Convinced that bodies, when too numerous, are little adapted for business, they have also felt that the power of giving their attendance might be more important than absolute superiority of scientific attainments. Some members have, however, been selected, though really non-resident, because it was believed that their colleagues might wish to consult them by letter. With these objects and views, the Council have done their best; but they have little doubt that some gentlemen have been overlooked and omitted, whose presence in the Committees might have been very desirable. The Society must consider this as in some degree a new system, to be perfected and improved by experience alone. Another question has occupied a share of the time of the Council during the last year. We have felt that the testimonial of recommendation for new Fellows has scarcely been sufficiently definite and precise in stating the grounds on which the candidate was recommended to the body of the Society. We have therefore thought it desirable to draw up forms of testimonial, some one of which may be adopted as most fit for each individual so recommended. We have thought this more fair, at the same time, to the meritorious candidate and to those electors who are otherwise left in the dark with respect to his claims for their suffrages. We hope and trust that this new regulation will not stand in the way of any candidate who would be a desirable addition to our number.

The vacancies in the list of our Foreign Members have been supplied by the election of M. Savart of Paris, Signor Melloni of Parma, M. Quetelet of Brussels, M. Hansteen of Christiana, Prof. Agassiz of Neufchatel, and M. von Martius of Münich, as those Fellows who were present at their election will remember.

I have to announce to you, Gentlemen, with great regret, the retirement of Captain Smyth from the office of Foreign Secretary, in consequence of his leaving his present residence for one at an inconvenient distance from London.

I have the honour, Gentlemen, to inform you that the Council have, by an unanimous decision, awarded the Royal Medals to Dr. Martin Barry and Mr. Ivory, and the Copley Medal for the year to Mr. Robert Brown; and I shall now beg leave to address myself to those three Gentlemen.

Dr. Barry.—It gives me sincere pleasure to bestow this medal on a gentleman who has so well deserved it, by researches in a difficult and important portion of animal physiology. Your merits have been appreciated by men much more capable of understanding the subject than I can pretend to be—by men selected by the Council of the Royal Society for their physiological science, who have felt the great value of the discoveries you have made by accurate and diligent research, aided by the skilful use of the microscope. I trust that the award of this medal will encourage you to persevere in the same course, and that future discoveries may add to your reputation and to that of the important profession to which you belong.

Mr. Ivory—It is not the first time that you have been addressed from this chair, and it gives me great satisfaction to follow the steps of my predecessors, Sir Joseph Banks and Sir H. Davy, by again bestowing a medal on one who is an honour to the Royal Society, and pre-eminently distinguished for his mathematical attainments. The labours of your life are too well known to the scientific world to require any eulogium from me, and I consider that in this tribute to your paper on astronomical refraction, we are rather doing an honour to ourselves than to you.

Mr. Brown—In conferring the Copley Medal on you for your valuable discoveries in vegetable impregnation, I am quite sure that the voice of scientific Europe will respond to the decision of the Council of the Royal Society. The Académie des Sciences has already pronounced on your merits, as also on those of Mr. Ivory, by electing you as well as that gentleman to a seat among their foreign members: and the University of Oxford has also, by an honorary degree, given you a similar testimonial. That you are one of our Fellows is to myself a circumstance peculiarly agreeable, as it must be to the whole body over whom I have the honour to preside. Your discoveries in the particular botanical question, for which I have to give you the Copley Medal, are so important, not only in a botanical, but also in a general scientific point of view, by showing the close analogies of animal and vegetable life, that the Committee of Zoology have felt it as much their province as that of the Committee of Botany, to recommend that the Copley Medal should be bestowed upon you; and the Council have come to an unanimous resolution to give it, though at the same time other gentlemen were recommended by other scientific committees, with whom even an unsuccessful rivalry would be no mean praise. I hope, Mr. Brown, that you may long enjoy life and leisure to pursue researches so valuable to science and so honourable to the country of which you are a native.

In drawing up the following notice of the losses which the Royal Society has sustained during the last year, in conformity with the practice of my predecessors, I have availed myself of the assistance of one of the Fellows, whose acquaintance with the labours of men of science peculiarly qualified him for the execution of a task which I could not myself have ventured to undertake. I therefore will not longer occupy your time by any further remarks of my own, but will conclude by the expression of my present wishes for the prosperity of the Royal Society, and for its success in furthering the noble ends for which it was instituted.

The Rev. Martin Davy was originally a member of the medical profession, which he followed, during a greater part of his life, with no inconsiderable reputation. He became a medical student of Caius College in 1787, and was elected to a fellowship in 1793, and to the mastership in 1803, the late illustrious Dr. Wollaston being one of his competitors. One of the first acts of his administration was to open his College to a more large and liberal competition, by the abolition of some mischievous and unstatutable restrictions, which had been sanctioned by long custom, and also by making academical merit and honours the sole avenue to college preferment: and he lived to witness the complete success of this wise and liberal measure, in the rapid increase of the number of high academical honours which were gained by members of his College, and by the subsequent advancement of many of them to the highest professional rank and eminence. Some years after his accession to the mastership, he took holy orders and commuted the degree of Doctor of Medicine for that of Theology, and in later life he was collated to some considerble ecclesiastical preferments. Dr. Davy had no great acquaintance with the details of accurate science, but he was remarkable for the extent and variety of his attainments in classical and general literature; his conversation was eminently lively and original and not less agreeable from its occasional tendency to somewhat paradoxical, though generally harmless speculations. He died in May last, after a long illness, deeply lamented by a large circle of friends, to whom he was endeared by his many social and other virtues.

Dr. Herbert Marsh, Bishop of Peterborough, and one of the most acute and learned theologians of his age, became a member of St. John's College in the University of Cambridge in the year 1775, and took his B.A. degree in 1780, being second in the list of Wranglers, which was headed by his friend and relation Mr. Thomas Jones, a man whose intellectual powers were of the highest order, and who for many years filled the office of tutor of Trinity College with unequalled success and reputation. Soon after his election to a fellowship, he went to Germany, where he devoted himself during many years to theological and general studies, and first became known to the public as the translator and learned commentator of Michaelis's Introduction to the New Testament. It was during his residence abroad that he published in the German language various tracts in defence of the policy of his own country in the continental wars, and more particularly a very elaborate "History of the Politics of Great Britain and France, from the time of the Conference at Pilnitz to the Declaration of War," a work which produced a marked impression on the state of public opinion in Germany, and for which he received a very considerable pension on the recommendation of Mr. Pitt. In 1807, he was elected Lady Margaret's Professor of Divinity in the University of Cambridge, an appointment of great value and importance, which he retained for the remainder of his life. On the resumption of his residence in the University, he devoted himself with great diligence to the preparation of his lectures on various important branches of Divinity, interposing a great number of occasional publications on the Catholic Question, the Bible Society, and various other subjects of political and theological controversy. In 1816 he was appointed Bishop of Llandaff; and three years afterwards he was translated to the see of Peterborough. * * Dr. Marsh was a man of great learning and very uncommon vigour of mind, and as a writer, remarkable for the great precision of his language and his singular clearness in the statement of his argument.

Professor Rigaud.—The father of the late Professor Rigaud had the care of the King's Observatory at Kew, an appointment which probably influenced the early tastes and predilections of his son. He was admitted a member of Exeter College, Oxford, in 1791, at the early age of sixteen, and continued to reside there as fellow and tutor until 1810, when he was appointed Savilian Professor of Geometry. He afterwards succeeded to the care of the Radcliffe Observatory, and the noble suite of instruments by Bird, with which it is furnished, was augmented, on his recommendation, by a new transit and circle, so as to fit it for the most refined purposes of modern practical astronomy: and we venture to express a hope that it will shortly become equally efficient and useful with the similar establishment which exists in the sister university. Professor Rigaud published in 1831, the miscellaneous works and correspondence of Bradley, to which he afterwards added a very interesting supplement on the astronomical papers of Harriott. In 1838, he published some curious notices of the first publication of the Principia of Newton; and he had also projected a Life of Halley, with a view of rescuing the memory of that great man from much of the obloquy to which it has been exposed; he had made extensive collections for a new edition of the mathematical collections of Pappus: and he was the author of many valuable communications to the Transactions of the Royal Astronomical Society, and to other scientific journals, on various subjects connected with physical and astronomical science. There was probably no other person of his age who was equally learned on all subjects connected with the history and literature of astronomy. He died in London in March last, after a short but painful illness, which he bore with a fortitude and resignation which might have been expected from his gentle, patient, and truly Christian character.

MR. WILKINS, Professor of Architecture to the Royal Academy—(see Journal, Vol. II. page 388.)

The REV. ARCHIBALD ALISON, senior Minister of St. Paul's Chapel, Edinburgh, was born in 1757, became a member of the University of Glasgow in 1772, and of Baliol College, Oxford, in 1775, and the degree of B.C.L. in 1784: he soon afterwards took holy orders in the English Church, and was presented to several ecclesiastical preferments by Sir William Pulteney, Lord Chancellor Loughborough, and Bishop Douglas of Salisbury. In 1784 he married the daughter of the celebrated Dr. John Gregory of Edinburgh, with whom he lived in uninterrupted happiness for forty years of his life. In 1814, he published two volumes of sermons; and at a later period, a very interesting memoir of his accomplished friend the Hon. Fraser Tytler Lord Woodhouslee. Mr. Alison was a man of very pleasing and refined manners, of great cheerfulness and equanimity of temper, of a clear and temperate judgment, and possessing a very extensive knowledge of mankind. He was habitually pious and humble-minded, exhibiting, in the whole tenor of his life, the blessed influence of that Gospel of which he was the ordained minister. All his writings are characterized by that pure and correct taste, the principles of which he had illustrated with so much elegance and beauty.

EDMUND LAW LUSHINGTON was born in 1766, at the lodge of St. Peter's College, Cambridge, of which his grandfather, Bishop Law, was master. He became a student, and afterwards a fellow of Queen's College in that University, and attained the fourth place on the mathematical tripos in 1787. After practising for some years at the bar, he was appointed Chief Justice of Ceylon, a station which he filled for several years with great advantage to that colony. On his return from the East, he was made Auditor of the Exchequer, and also received from his uncle Lord Ellenborough the appointment of Master of the Crown Office. He was an intimate friend of Wollaston and Tennant; and though withdrawn by his pursuits from the active cultivation of science, he continued throughout his life to feel a deep interest in its progress. His acquaintance with classical and general literature was unusually extensive and varied, and he had the happiness of witnessing in his sons the successful cultivation of those studies which other and more absorbing duties had compelled him to abandon. Mr. Lushington was a man of a cheerful temper, of very courteous and pleasing manners, temperate and tolerant in all his opinions, and exemplary in the discharge both of his public and private duties: few persons have ever been more sincerely beloved either by their friends or by the members of their families.

MR. GEORGE SAUNDERS was formerly architect to the British Museum, where he built the Townley Gallery; he was a diligent and learned antiquary, and the author of a very interesting and valuable paper in the twenty-sixth volume of the Archæologia, containing the results of an inquiry concerning the condition and extent of the city of Westminster at various periods of our history.

The only foreign members whom the Royal Society has lost during the last year are the Baron de Prony, one of the most distinguished engineers and mathematicians of the age; and the venerable Pierre Prevost, formerly Professor of Natural Philosophy in the University of Geneva.

GASPARD CLAIR FRANÇOIS MARIE RICHE DE PRONY, was born in the department of the Rhone, in 1755, and became a pupil at an early age, of the Ecole des Ponts et Chaussées, where he pursued his mathematical and other studies with great application, and with more than common success. He was subsequently employed as an adjunct of M. Perronet, the chief of that school, in many important works, and particularly in the restoration of the Port of Dunkirk; and in 1786, he drew up the engineering plan for the erection of the Pont Louis XVI., and was employed in superintending its execution. M. de Prony had already appeared before the public, first as the translator of General Roy's "Account of the Methods employed for the Measurement of the Base on Hounslow Heath," which was the basis of the most considerable geodesical operation which had at that time been undertaken; and subsequently as the author of an essay of considerable merit, "On the Construction of Intermediate Equations of the Second Degree." In 1790 and 1797, appeared his great work in two large volumes, entitled *Nouvelle Architecture Hydraulique*, which is a very complete and systematic treatise on Mechanics, Hydrostatics and Hydraulics, and more particularly on the principles of the steam-engine and hydraulical engineering. In 1792 he was appointed to superintend the Cadastre or great territorial and numerical survey of France—a gigantic undertaking, the subsequent execution of which, during the revolutionary government, combined with the establishment of the bases of the decimal metrical system, gave employment and developement to so many and such important scientific labours and discoveries; among many other laborious duties the formation of the extensive tables devolved upon M. de Prony, who, in the course of two years organized and instructed a numerous body of calculators, and completed the immense *Tables du Cadastre*, which are still preserved in MSS. at the library of the Observatory in seventeen enormous folio volumes. M. de Prony became Directeur-General des Ponts et Chaussées in 1794, and was nominated the first Professor of Mechanics to the Ecole Polytechnique—an appointment which led to the publication of many very important memoirs on mechanical and hydraulical subjects, and on various problems of engineering, which appeared in the Journal of that celebrated school. He declined the invitation of Napoleon to become a member of the Institute of Egypt—a refusal which was never entirely forgotten or pardoned. In the beginning of the present century he was engaged in execution of very extensive works connected with the embankments towards the embouchure of the Po, and in the ports of Genoa, Ancona, Pola, Venice, and the Gulf of Spezzia; and in 1810, he was appointed in conjunction with the celebrated Count Fossombroni, of Florence, the head of the *Commissione de l'Agro Romano*, for the more effectual drainage and improvement of the Pontine Mashes. The result of his labours in this very important task, which he prosecuted with extraordinary zeal and success, was embodied in his *Déscription Hydrographique et Historique des Marais Pontins*, which appeared in 1822, which contains a very detailed description of the past, present and prospective conditions of these pestilential regions, and a very elaborate scientific discussion of the general principles which should guide us, in this and all similar cases, in effecting their permanent restoration to healthiness and fertility. After the return of the Bourbons, M. de Prony continued to be employed in various important works, and more particularly in the formation of some extensive embankments towards the mouth of the Rhone. In 1817 he was made a member of the *Bureau des Longitudes*, and in the following year he was elected one of the fifty foreign members of the Royal Society: in 1828 he was created a Baron by Charles X., and was made a peer of France in 1835. He died in great tranquillity at Aonières, near Paris, in July last, in the 84th year of his age. The Baron de Prony was a man of singularly pleasing manners, of very lively conversation, and great evenness of temper. He was one of the most voluminous writers of his age, generally upon mathematical and other subjects connected with his professional pursuits; and though we should not be justified in placing him on the same level with some of the great men with whom he was associated for so many years of his life, yet he is one of those of whom his country may be justly proud, whether we consider the extent and character of his scientific attainments, or the great variety of important practical and useful labours in which his life was spent.

PIERRE PREVOST was born in 1751, and was originally destined to follow the profession of his father, who was one of the pastors of Geneva. At the age of twenty, however, he abandoned the study of theology for that of law, the steady pursuit of which, in time, gave way to his ardent passion for literature and philosophy: at the age of twenty-two he became private tutor in a Dutch family, and afterwards accepted a similar situation in the family of M. Delesert, first at Lyons, and afterwards at Paris. It was in this latter city that he commenced the publication of his translation of Euripides, beginning with the tragedy of Orestes—a work which made him advantageously known to some of the leading men in that great metropolis of literature, and led to his appointment, in 1780, to the professorship of philosophy in the college of Nobles, and also to a place in the Academy of Berlin, on the invitation of Frederick the Great. Being thus established in a position where the cultivation of literature and philosophy became as much a professional duty as the natural accomplishment of his own wishes and tastes, he commenced a life of more than ordinary literary activity and productiveness. He died on the 8th of April, in the 88th year of his age, surrounded by his family, and deeply regretted by all who knew him.

USE OF VARNISH OF DEXTRINE IN THE FINE ARTS.—In the sitting of the Academy of Sciences, Monday, 26th August, Baron De Silvestre made the following remarks on the occasion of M. Arago's communication on the preservation of photographic images. He observed that it would be interesting to try dextrine for this purpose, as he himself, for more than two years, had successfully used this substance for varnishing pictures newly painted in oil, water colour drawing, coloured lithographs, and for the permanent fixation of pencil drawings. He had also obtained from dextrine a glue, which he found superseded with advantages all other gluey substances, and particularly mouth glue. In these different applications dextrine is mixed with water in different proportions; two parts to six of water for varnish, and in equal parts for glue. He observed that he always added one part of alcohol in the composition of the varnish, and half a part in that of the glue. The mixture should be always filtered before being used for varnishing pictures and fixing drawings, and in this latter case, a fine wet muslin should be spread over the drawing, before covering it with the mixture of filtered dextrine. The description of these processes, and of the results obtained, is given in the *Bulletin de la Societé d'Encouragement pour l'Industrie Nationale*, for the 2nd of August, 1837.

ANTIQUITIES OF THE CITY OF LONDON.

Sir—Having been called in by the Rector of *Saint Mary Aldermary and Saint Thomas the Apostle*, to inspect the North Wall of the Church of Saint Mary Aldermary, Watling-street, I was led to the following conclusion, after a most careful examination, as to the antiquity of portions of that wall, which may prove interesting to many of your readers.

In rebuilding the church after the memorable fire of London, it seems that Sir Christopher Wren not only retained the original line of the north wall, but finding it unnecessary to pull it down entirely, left it untouched as far up as a string-course which formerly ran along the whole length of the church, under the sills of the windows of the north aisle, traces of it being perfectly discernible to an eye familiar with the remains of antiquity, from the north-east angle of the building to the north doorway. There are also remains of the original basement-moulding, and the original buttresses still exist with the stringcourse profiled round them, they are five in number, and, in one or two places, the face of their ashlar is as perfect as when first worked. The original ashlar of the whole of this wall still remains from the level of the ground to that of the string-course before mentioned, and indeed a small portion of it is left some five or six feet above the string-course, immediately adjoining the easternmost buttress. The rebuilding is clearly defined by the rough masonry of this wall above the level of the string-course, which seems to have been intended at the time as a party-wall between the church and the glebe-houses, not only on account of its not being faced, but also on account of the entire absence of openings for light. The north doorway, with its discharging arch in rough masonry is evidently an insertion in the original wall, the recesses over the doorway seem to have been left as cupboards for the adjoining house, as the masonry of their arches is coeval with that of the discharging arch over the doorway. Before the fire, I have no doubt, this wall was quite unincumbered by buildings, first, because the ashlar still remaining shows a fair face; secondly, because the buttresses still exist, showing also a fair face; and thirdly, because remains of the basement-moulding and the string-course, both being exterior features, can be clearly pointed out. There must therefore have been a space, originally, between the church and the glebe, which seems to have been used as a burial-place, as human bones were some years ago found near the footing of this wall. This space, on account of Watling-street having been either widened at the time or removed farther southwards, (21½ feet were cut off from the glebe land in front towards the street, see Oliver's Survey, vol. 2, p. 155,) was, by the Decrees of the Judges, made part and parcel of the glebe; and this accounts satisfactorily for that wall having been, in the rebuilding, made a party-wall, and also for the right of way having been reserved to the parishioners from the street, through the glebe, up to the north doorway of the church.

I have made a careful drawing of these remains, which I shall be most happy to show to any one who, like myself, may take an interest in old gothic buildings.

Your's, &c.,
Thos. E. Walker.

2, *Keppel-street, Russell-square, Dec.* 3, 1839.

ISLE OF SHEPPY.

Sir—Having read an extract from the Cinque Ports Chronicle in this month's journal, on "The Encroachments and Recessions of the Sea," in which the only reason assigned for the former is the action of the sea in its ceaseless beatings against the shore; I am induced to bring to your notice the Isle of Sheppy, where from another cause the sea is making a more rapid encroachment than perhaps any other part of England: so much so, that I think in a very few years the greater part of Minster Hill, the Station Houses at East End Lane, and Hensbroche will be swallowed up by the sea. Indeed the extent of bank left at low water, particularly during spring tides, and the very great distance from the beach that the stone for cement is dug up, (I *believe* the Rudis Helmontia) prove that the island was once of much greater extent than at present, and from my observation of the land slips that have taken place since I came here in June last, I should certainly say they were caused by underground springs endeavouring to find an outlet, and that by proper drainage much valuable land might be saved. Indeed the shelving beach or strand caused by the former destruction of the island is now a strong natural protection to it, and that the present almost daily loss is owing to want of care in directing the numerous springs into a proper channel.

I am, Sir, your obedient servant,
C. F. Parkinson.
Captain 73rd Regiment.

STEAM BOAT PROPELLERS.

Experiments by George Rennie, Esq., communicated to the Editor of the Railway Magazine.

I herewith send you the average result of a series of experiments I have made on the comparative merits of several instruments which have been tried for propelling vessels through water, under similar circumstances. In order, therefore, to arrive at this knowledge, three different sets of experiments were tried: first, on a model wheel, of two feet in diameter, fixed in a trough of water, and moved by a weight falling through equal height; secondly, by means of a boat to which the different kinds of propeller were adapted, so as to render the circumstances similar in every respect; thirdly, by means of a small steamer, of moderate dimensions, so as to enable the experiments to be made in still water, and thus obtain more accurate results than could possibly be obtained in a tidal river like the Thames. The following are the results on the model—

No. of Experiments.	Diameter of wheel.	Time in seconds.	Area of floats immersed.	Weight suspended.	Area of one float.	
6	2 ft.	15·5	12 in.	4 lbs.	6 in.	Rectangular floats.
6	2 ft.	15·1	9 in.	4 lbs.	3 in.	Trapezium floats.

An experiment was then tried by immersing the rectangular floats to twice their depth. The result was to increase the time of the 4lb. weight falling to 32 seconds, or double the resistance when immersed to the ordinary depth of the float, while the trapezium-shaped float, doubly immersed, only required 16 seconds for the 4lb. weight to fall through the same space; thus, proving the great defect of the paddle-wheel, as applied to all sea-going steam-vessels, so that when deeply laden with coals at the first part of their voyages, the engines can only make half their proper number of strokes. The British Queen, for instance, the engines of which are frequently reduced to nine, instead of seventeen or eighteen, the full number of strokes. These experiments have been repeated again and again, before competent witnesses, and always with the same results.

Secondly—with different kinds of propellers attached to the same boat.

The following are the comparative results:—

Table in which are compared the Performances of the Screw-Propeller, Conoidal-Propeller, and Paddle-wheels.

Distance travelled in feet.	Time in seconds.	Revolution of winch.	Revolution of winch p. min.	Speed of boat in miles p. hour.	Conditions of Experiment.
660	201·0	110·7	42·0	2·2	Screw Propeller, 17 in. diameter, 226 ins. area; revolved with a velocity five times that of the winch.
660	155·25	108·25	41·8	2·8	Paddle-wheel with 12 rectangular floats, each float 9½ × 4; area of floats immersed 228·8 ins.; extreme diameter of wheel, 3 ft. 3 in.
660	155·75	120·75	46·5	2·8	Paddle-wheel, with 12 trapezium-shaped floats (*obtuse* ends down), each float 9½ × 4; area of floats immersed, 103 ins.; extreme diameter of wheel, 3 ft. 6½ ins.
660	153 5	121·75	47·5	·9	Paddle-wheel, with 12 trapezium-shaped floats (*acute* ends down), each float 9½ × 4; area of floats immersed, 107 ins.; extreme diameter of wheel, 3 ft. 10¾ ins.
660	135·5	89·6	39·6	3·3	Conoidal propellers, 17 ins. diameter; 144 ins. area; revolved with a velocity five times that of the winch.

N.B.—The above experiments were made with a boat such as is used in the whale fishery; its length was 27 feet, its breadth 5 feet, its depth 2 feet 1 inch, and its weight, with ballast and persons on board, 2828 lbs., the area of its midship section 183 square inches. In each experiment the winch was driven by two men.

Conclusions.—From the preceding table it appears that the relative merits of the screw propeller, the conoidal propeller, and the common and trapezium-shaped floats are precisely in the order in which they stand in the table; that the screw is inferior to the common paddle-wheel in the ratio of 2·2 to 2·8, with the spear-pointed paddles as 2·2 to 2·9, and with the conoidal propeller as 2·2 to 3·3; that of the trapezium-shaped floats as 2·8 to 2·9, and that with the obtuse angle down is equal. It may be objected to these experiments, that the boat being worked by men, the results cannot be depended upon, on account of the irregular, and, perhaps, over-zealous action of animal power. But, after a few trials, the action soon becomes as regular, and may be calculated upon with nearly the same accuracy, as a steam-engine.

Thirdly—By means of a steam-boat. This boat was kindly lent by the London and Westminster Steam-boat Company; and is of the following dimensions:—

Length.......................... 57 feet.
Breadth .... 6 feet.
Depth .... 3 feet.
Power—two engines (vibrating) of 5 horse power—36 strokes per minute.

Table in which are compared the Performances of Rectangular and Spear-shaped Floats, with the "Pink" steamer, in the West India Import Dock, in November, 1839.

Distance travelled in feet.	Time in seconds.	Revolutions of cranked shaft.	Revolutions of cranked shaft per. min.	Speed of boat in miles p. hour.	Conditions of Experiments.
1320	138·	84·0	36·5	6·7	Wheels fitted with 10 rectangular floats 23 9 ins. 207 s. ins.; area of floats immersed, 635·6 s. ins.; extreme diameter of wheel, 7 1.
1320	145·75	87·5	36·0	6·34	Wheels fitted with 10 trapezium-shaped floats (*acute* and *obtuse*), 18 11½ 103·5 s. ins.; area of floats immersed 132·25 ins.; extreme diameter of wheel, 8 10.

Conclusions.—From the results of these experiments we are justified in concluding that the trapezium-shaped float, containing only one-half of the surface of the common paddle, and one-third of its width, will have equal hold of the water, and propel the vessel equally as fast, with a less expenditure of power; but its properties are not only confined to this.

In the first place, they are less weight and first cost, by at least one-half.

Secondly—They present less surface the wind, particularly against a head-wind.

Thirdly—They enter the water without the shock and vibrations which are experienced with the common wheel, and without raising the cascade of water appertaining to the old form of paddle.

Fourthly—They work nearly as well when deeply immersed, with the exception of the slight resistance arising from the edges of the arms.

All which properties have been witnessed and tested by competent judges.

GAS PRODUCED BY A NEW PROCESS.

An experiment in gas-lighting by the Comte de Val Marino was made on Thursday evening on a piece of waste ground at the back of Fetter-lane, in the presence of several scientific gentlemen, who were invited to witness the result. A small gasometer was erected for the purpose, which was connected by tubes with a furnace built of brick, and containing three retorts, one of which was supplied with water from a siphon, another was filled with tar, and both being decomposed in the third retort, formed the sole materials by which the gas was produced. The process appeared to be extremely simple, and the novelty of the experiment consisted in the fact, that the principal agent employed to produce the gas was common water combined with tar; but, according to the theory of the inventor of this new species of gas, any sort of bituminous or fatty matter would answer the purpose equally as well as pitch or tar. After the lapse of about half an hour employed in the experiment, during which time the process was explained to the company, the gas was turned into the burners, and a pure and powerful light was produced, perfectly free from smoke or any unpleasant smell. The purity and intenseness of the flame were tested in a very satisfactory manner, and those who witnessed the experiment appeared perfectly satisfied with the result. The great advantage of this sort of gas over that produced from coal consists, it was said, in the cheapness of the materials employed in its production, the facility with which it is manufactured, and the perfection to which it is at once brought, without the necessity of its undergoing the tedious and expensive process of condensation and purification; for in this instance, as soon as the preliminaries were completed, the light was produced in a perfect state within a few feet of the gasometer, which, although of inferior size, was said to be capable of affording light for 10 hours to at least 500 lamps or burners. With regard to the comparative expense, it was also stated that 1000 cubic feet of gas manufactured by this process, could be supplied to the public for about one third the price now charged by the coal-gas companies; and it was said to be equally available for domestic use, and more safe than the common gas, inasmuch as small gasometers might, at a trifling expense, be fixed at the back of grates in private dwellings, from which the gas could be conveyed in India-rubber bags to any part of the house, thereby preventing the many accidents which occur by the use of tubes and pipes. The Count de Val Marino, who has conquered the difficulty hitherto experienced in bringing this species of gas into use, superintended the arrangements, and evinced a natural anxiety to bring his experiment to a successful issue. He has taken out a patent for his discovery, and he has improved upon the burners now in use, so as to render the light produced more pure and intense. For this improvement he is also secured by a patent. How far gas of this description can be brought into general use, or whether in point of economy the public would be benefited by its adoption, are questions which we have not the means of deciding, and, without hazarding any opinion on the subject, we can only say that the experiment, as far as it was tried in this instance, appeared to be quite successful.—*Times.*

AMERICAN PATENTS.

(From the Journal of the Franklin Institute.)

For "*An improved Eccentric Brake, for arresting the motion of Railroad Cars.*" Ephraim Morris, Bloomfield, Essex county, New Jersey, Sept. 19.

Between the two wheels on each side of a car there is to be a cam wheel, one part of which is to be a segment of a circle, resembling the periphery of one of the wheels; another portion of the periphery of the cam is in a straight line, probably of two feet or more in length, and the cam may be made to roll round on its circular, or curved part, and to bring this straight part upon the rail, which, whilst it bears upon it, will lift the wheels, at one or both ends, therefrom. The straight portion of the cams are furnished with flanches which embrace the rail. This part, by its friction upon the rail, is to operate as a brake upon an inclined plane, or elsewhere. The claim is to the foregoing arrangement of the respective parts.

When it is desired to relieve the brake, this is effected by backing the cars, when the ordinary wheels are made to rest upon the rail, the lower side of the brake being then free from them; there are, of course, some particular devices described which we have not noticed, nor do we think it necessary, being apprehensive that the contrivance is not destined to be adopted.

For "*A Machine for cutting the Teeth of Circular Saws.*" Thaddeus Sellick, Haverstraw, Rockland county, New York, September 19.

One, two, or more, steel plates, prepared to have teeth cut upon them, are to be placed upon a vertical spindle capable of revolving on its two ends. These plates are to be made to bear against a revolving cutter, consisting of an endless screw, the thread of which is in such form as to cut a saw tooth. A cutter two inches in diameter and half an inch in thickness, has been used for the purpose. The revolution of the cutter will cause that of the saw plates, which are borne up against it. It is remarked that the teeth of straight saws may be cut by a similar device.

"What I claim, is the employment of a circular revolving cutter, having a thread or channel on its periphery, running in the manner of an endless screw, and so arranged and combined with the other parts of the machinery employed, as to cause the cutter to cut, and to feed the plates to itself, by its own action, the whole operating substantially in the manner above set forth."

For "*An Improvement in the mode of preserving Timber.*" Edward Earl, Savannah, Georgia, September 20.

We published in our last number, the specification of a patent for a similar purpose, the gentleman above named being one of the patentees. The mode of procedure in the present case is like that described in the former patent; that is, the timber is to be boiled in the solution by which the preservative quality is to be communicated, which solution is to consist of sulphate of copper, (blue vitriol,) and sulphate of iron, (copperas,) dissolved in water. One part of sulphate of copper to three of sulphate of iron, are to be taken, and about three pounds of the mixed salts added to every gallon of water. The timber after being bored through its length, is to be boiled, and afterwards suffered to cool in this solution. The claims made, are to "the boiling of timber as described, in a solution of sulphates of iron and of copper; applying this solution to the interior as well as the exterior of the timber, by means of the central perforation when the size of the timber requires it, as the most effectual mode of protecting it from the ravages of insects, and of rot. I do not claim the saturating of timber by a solution of sulphates in water when applied cold, but confine my claim to boiling it, as above set forth, in that solution, during from two to five or six hours, or more."

For "*A Gravel Pump.*" Laura Rice, administratrix of J. J. Rice, and Ebenezer Rice, Salina, New York, August 15.

"This pump, or machine, is inserted in a well, or shaft, which should be properly tubed with cast or sheet iron, or other proper material, with space to permit it to pass readily, and having a rope, or cords, connected with the end of the piston, is worked in the manner of a pump until sufficiently charged with the substance to be removed, when it is raised by a windlass, or other power. It is particularly adapted to the excavations of shafts for brine, and was discovered whilst excavating wells for that purpose, as no instrument was known which would readily raise the gravel from the beds without great delay and difficulty, and at the same time leave the sides of the well bare and pervious to the transmission of brine, the ordinary process of drilling merely crowding the staves from the shaft, and rendering the sides of the well compact, hard, and nearly excluding the passage of small streams of brine into the well."

The form of the exterior of the machine is that of two cylinders differing in size, the smaller standing above the larger; the lower cylinder is to be about 11 or 12 inches in diameter, and 21 in height; the upper one may be 8½ inches in diameter, and 15 in height; they are connected by an offset, are hollow, and made of cast iron; the upper cylinder forms a pump chamber in which a piston is to work. The lower cylinder constitutes a receiver to retain the sand and gravel drawn into it by the action of the pump. In the bottom of the lower cylinder there is a round opening of six inches in diameter, and the upper and inner edge of this opening is surrounded by pieces of whalebone, or other elastic material, which rise from it so as to form a cone somewhat like that of the pointed converging wires in some rat traps; these may be six or seven inches long. They allow of the passage of stones and gravel into the chamber, and prevent their return. This elastic material is surrounded by a sleeve of cloth, which admits sand to pass up and around it.

The claim is to "the manner of connecting and combining the respective parts of the above described machine, for the purpose of excavating wells and shafts, and the removal of sand and gravel therefrom: that is to say, the combination of the exhausting apparatus with the cylinder, the conical bars of whalebone or other material, and the canvas surrounding the same, constructed and operating in the manner set forth."

PRESERVING TIMBER BY LIME WATER.

Specification of a Patent for an improvement in the mode of preserving Timber. Granted to Samuel Ringgold, of Florida, and Edward Earle, of Savannah, State of Georgia, Aug. 6, 1838.

(From the Franklin Journal.)

The nature of our invention consists in applying heat, by boiling in strong lime-water, to the interior as well as to the exterior of timber, according to the size and kind of timber, and the use in which it is to be employed may admit, or require, for the destruction and prevention of worms in it, and for the correction or removal of the corruptible sap, and the occupation of its place by a preservative substance.

We first bore the timber, if it be of a size sufficient to admit of it, through the centre, making the perforation of a calibre proportioned to the size of the piece, say from half an inch to an inch and a half, or two inches. Then we boil it in strong lime water for a length of time proportioned to its size, as four to six hours, if it be twelve inches square, and so in proportion to its substance; and when the timber has had the heat and fluid conveyed through its whole substance, it is to be removed to a shed, where, protected from the sun and wind, it may gradually dry. Finally, before it is used, the perforation through the centre is to be completely filled with dry lime, or with petroleum, or coal tar, as the purpose for which it is intended may make preferable, and plugged by wood of the same kind, and prepared in the same manner. Also, if the use to which the timber is destined be such as to admit of it, the exterior may be payed, or coated with hot petroleum, or coal tar.

What we claim as our invention, and desire to secure by letters patent, is the boiling of timber in lime water, as above set forth. We apply the fluid to the interior as well as exterior of the timber, by means of the central perforation, when the size of the timber requires it, as the most effectual mode of preserving it from the ravages of insects, and from rot. We do not claim the saturating of timber by a solution of lime in water when applied cold, or when heated by that heat which is generated in the slacking of the lime, but confine our claim to the boiling it in lime water during one, two, three, or more hours.

Remarks by the Editor.—The plan of impregnating timber with lime, by soaking it in lime water, is quite old, but we have never yet seen any evidence of its utility. This is an assumed effect, but one which, we believe, yet remains to be proved. The only substantial difference in the plan above proposed, and that formerly assayed, is in the boiling process, and this we think of a very doubtful use. Timber may be rapidly seasoned by boiling, the moisture within it being converted into vapour, and consequently escaping through the pores, a condition not the most favourable to the entrance of a solution; the allowing it to cool in and with the liquor, might probably promote saturation. There is another fact of some importance in the process, provided the thing itself is of any value, namely, that the colder the water the greater is the quantity of lime held in solution, and of course more would enter the pores in a cold than in a heated vessel. It is not worth while, however, to extend our speculations upon the best mode of getting the lime in until we have ascertained the fact that when it is there it will produce some good result.

HER MAJESTY'S DOCK-YARD, WOOLWICH.

Extensive works are at present in operation at the west end of the yard, for the formation of a large graving dock, which is to afford accommodation to the first class government steamers. The site for the new dock is the south side of the basin or wet dock, which is principally used for fitting out steamers; the situation thus chosen allows of room for another dock of like dimensions being constructed to the eastward of it, in the event of such extended accommodation being required. The works, which are contracted for, and being executed by, Messrs. Grissell and Peto, under the direction of Mr. Walker, the engineer, are of great magnitude, comprising likewise the formation of a wall across the entrance to the old concrete dock, which was undertaken by Mr. Ranger, and constructed of his patent concrete; this material was not found sufficient to keep down the land springs, and has, consequently, been relinquished. For the formation of the new dock, a cofferdam has been constructed in front of the proposed entrance, nearly a hundred feet in length, consisting of parallel rows of close piling driven into the solid ground, as that portion of the basin wall within the cofferdam will necessarily have to be removed, great strength is required in the framing of the timbers for its support, which appears to have been amply provided for by the excellent arrangement of shoring adopted. Considerable progress has been made with the excavation for the dock, which has been taken out for nearly its entire surface, to a depth of from twenty to thirty feet below the quay level; to prevent the slopes of the excavation from slipping, and likewise to save room, the whole area of the dock is being enclosed with sheet piling, which, as the masonry of the side walls advances, will be removed if found advisable. The dock will be constructed of granite, either from the New Granite Co.'s quarries, near Plymouth, or from the Haytor quarries in Devonshire. A large quantity of stone is now upon the ground partly worked. The length of the dock will be 265 feet from the semicircular head to the inside of the gates, the width at top 80 feet and at bottom 37 feet, the clear width at the entrance 65 feet, the depth 26 feet from the quay level to the invert, being equal to 22 feet depth of water at high water, Trinity standard; the entrance gates and plan of working them will be according to the most approved construction.

The sides of the dock will be formed in steps or altars, varying in height from nine to sixteen inches, and in width from nine to fifteen inches, with the exception of one called the Broad Altar, about midway down which will be eighteen inches in width; the object of these altars is for the convenience of placing the shores against the hull of a vessel at any height, and for resting the ends of spars for staging; that called the Broad Altar is made wider than the others, for walking upon in examining the sides of the vessel under repair; the curve given to the altars is calculated to suit nearly the form of a vessel, and likewise affords, as before stated, the opportunity of shoring at any height, which is precluded by the common form of docks where very deep altars are used, and they will also enable the workmen to get up and down at any part of the dock with great facility, but for general purposes, a staircase of more easy ascent will be constructed at the head of the dock; slips for letting down and raising timber, &c., will be formed at the head, and likewise on each side of the dock. The stones of the invert forming the bottom of the dock will radiate, as likewise the altar stones as high as the Broad Altar, the whole thus forming an arch to resist the upward pressure, and the masonry above, as likewise the coping, will be in stones of large dimensions, the whole backed with brickwork and concrete. The walls at top will be four feet thick, and at bottom 25 feet 6 inches, and the total width of the foundations will be 88 feet, under which a body of concrete three yards thick will be carried down to the gravel. The apron at the entrance will be supported upon bearing piles, and protected in front with sheet piling made water-tight. As an engine and pumps will be required for emptying the dock, a pumping engine is now being constructed by Messrs. Bolton and Watt, and will be fixed ready for working by the time the dock is finished. Large brick culverts, furnished with proper penstocks, will be formed for drainage to the engine-well, and also for filling the dock when required for floating a vessel out. During the works, the large area excavated for the dock will be kept clear of water by a temporary engine and pumps, which are in course of erection. From the above some idea may be formed of the magnitude and importance of the works now in progress at Woolwich Dock Yard, which, with other improvements now being executed under the direction of Captain Brandreth and Lieut. Dennison, of which we hope shortly to give an account, will render this yard a very complete establishment for that important department of Her Majesty's navy, the steam marine. We will endeavour, at some future opportunity, to give further particulars of these interesting works during their progress.

Peterboro'.—The Justices for this liberty, at their meeting on Saturday the 30th ult., adopted the plans of Mr. Dunthorne, of Hanover-street, London, for the new gaol about to be erected for this liberty. Many very meritorious plans were sent for the inspection of the Justices; and amongst them, those of Mr. Sibley, of Great Ormond-street, and Mr. Alexander, of Adam-street, Adelphi, London, and of Mr. Walter, of Cambridge, elicited the greatest approbation. Mr. Blore, who is erroneously stated by a cotemporary to have been the successful candidate, did not send in a design.—*Stamford Mercury.*

ON THE POWER OF THE STEAM ENGINE.

At the last meeting of the Cornwall Polytechnic Society, held at Falmouth, Mr. Snow Harris read an abstract of an interesting and valuable paper on the Steam-engine, by Professor Moseley, he passed a high eulogium on that gentleman whose paper, he said, possessed a great deal of interest to the working engineer and practical miner. The details of the paper would, however, be too tedious to bring before a mixed audience, and he had therefore abstracted the principal points which it was necessary to bring under their considertion. Professor Moseley appeared to think that the efficiency of a steam engine could be measured only by observations of the cylinder itself, because the estimate at any other place was less than the actual deficiency on account of friction and other causes. Hence they could not tell *à priori* of what the engine was capable. If they had a good measurement of the efficiency at the cylinder, and also of the work actually performed, they should then arrive at a true estimate of the power of the engine, and also of the loss by friction, &c., by subtracting one from the other. In the Cornish engines they had already the efficiency of the working parts; they required, therefore, the only observations at the cylinder. It was the difference of these which was the efficiency for the pit work, and of so much importance to the adventurer and engineer. Professor Moseley proposed to arrive at the efficiency of the cylinder by connecting a second smaller cylinder with it of about six inches diameter, so as to allow of the steam acting upon a spring through the medium of a solid plug in the latter. The writer thought the effective pressure upon this plug as indicated by the quantitatum measurement by means of the steel spring will be always equal to that upon an equal area of the piston of the engine; so that knowing one of these pressures they could always determine the other—namely, the effective pressure. The author proceeded to explain by diagrams a practical method of carrying out his general principle. He further thought that they not only wanted to know the effective pressure throughout the whole duration of the stroke, but also how much of the stroke was described under any given pressure. The author furnished methods for arriving at this important element which were well worthy of attention, and were such as to apply either to a long period as a month, or a short period of six hours. The Professor considered that the *out* as well as the *in* stroke should be registered, and he gave an arrangement for the purpose, and the results were registered upon indicator diagrams, different from those of Watt, and upon an area sixty times as great. There seemed but little doubt that the author of this paper, which must be considered as an extremely important one to the practical miner and engineer, had succeeded in inventing methods for arriving at the efficient power of the steam engine. It was the mechanical details which required consideration. They must obtain very perfect springs calculated to yield through spaces proportioned to the pressures. This was a vital affair, for should not such be the case the indications would be erroneous. The author thought that this property could be given to spiral springs, as well as to bow springs of a given form; and that with due correction for the friction of the small cylinder, the method might be made practically perfect. Mr. Jordan, with his usual ability, had given a drawing of the indicator, and had contributed largely to its mechanical advancement. Professor Moseley proposed to call this instrument the *pit work* counter, because it indicates, by comparison with the counter in present use, the amount of the pit work. Mr. Harris concluded by observing that this was a brief abstract of the very valuable paper furnished by Professor Moseley, and he was only sorry that the time allowed him had not permitted him to do Professor Moseley more justice than he had on the present occasion.

Steam Apparatus.—There is in the Oxford Union workhouse a steam apparatus by means of which the whole of the clothing and other articles used in it are washed, dried, and ironed, in an incredibly short space of time. We have lately been afforded an opportunity of witnessing this useful piece of mechanism in operation, on which occasion no less than 1235 articles of wearing apparel, bed-clothing, &c., were washed, dried, and ironed, in two days, with the assistance of only eight women and two girls from the school. It is the invention of James Wapshare, Esq., of Bath, for which we understand he has obtained a patent, and was some time since erected in one of the wings of the building solely devoted to the purposes of a laundry, at the expense of the chairman of the Board, the Rev. N. Dodson. The apparatus consists of a small steam boiler, with two pipes for the conveyance of steam. By the one pipe the steam is conducted to the coppers used for boiling the clothes and supplying the washers with hot water, by the other the steam is carried to a closet in which the linen is to be dried. The exterior of this closet is a wooden frame covered with zinc, within it is fitted up with pipes, increasing in number according to the extent of drying power required. These pipes are arranged horizontally one above another, resembling a turnpike gate; excepting that the rails are connected at one end only by a bend or turn, thus forming a continued duct for the steam. The steam is admitted at the upper pipe, and passes its condensed water at the lowest. On either side of this tier of pipes is a movable clothes horse, which is drawn out to be hung with clothes. Upon the construction of these horses the operation of drying in a great measure depends. They are made close at the top of the box, so that no heat may escape over them, and the clothes are so disposed on them as to form an entire sheet, completely enclosing the pipes, and preventing any escape of the heat radiating from the pipes, except by passing through the clothes to be dried. This disposition of the clothes is easily accomplished, but difficult of description. On the outside of the horses, or on that side which is not next the pipes, a valve or opening is made on the top of the box, and a current of air being admitted at the bottom, the steam from the clothes is carried off as fast as it is generated. One set of these pipes, with two horses, would be sufficient for any moderate family. In an establishment so extensive as an Union house more is required. In the closet erected are three ranges of pipes, and consequently six horses or two to each range, having an air space, with its valve between each set of horses. Attached to the flue that surrounds the boiler is a small oven for heating the irons, so that the whole operation of the laundry, as far as heat is required, is simultaneously effected by one fire.—*Oxford Herald.* [We insert this notice, not for its novelty, but for its utility, and to show the application of steam to domestic purposes, in the erection of extensive buildings intended to contain a large number of inmates. We cannot, from the above description, ascertain what claim Mr. Wapshare can have for a patent, as similar arrangements have been adopted many years past.—Ed. C. E. & A. Jour.]

Harbour Crane.—A crane capable of raising great weights at the harbour having been found indispensable, a considerable time since, Mr. Leslie, engineer to the harbour, executed a plan for a machine capable of raising thirty tons. The merit of the design has been very extensively acknowledged among professional men, and those who are initiated in mechanics. Mr. Peter Borrie, the contractor for the work, has been engaged for some time past in casting the different parts of the crane. The novelty of the design, and the magnitude of the work, evince the skill and attention which must have been bestowed upon its completion. The gross weight of the post, including the back and side tension-bars, friction collar, hoops, &c., is no less than twenty-five tons, or within ten tons of the weight which it is intended to lift. The pedestal for this crane is a beautiful piece of masonry; and rising considerably above the quay, it was necessary to raise the post to an elevation of fifty-five feet before it could be put into its place. This was done by two tackles and crab windlasses of great power—the upper blocks being fastened, at a height of sixty feet, to the apex of three shear poles. The whole time occupied in the transit of the axle pole, and in raising and lowering it into the cast-iron cylinders, did not exceed six consecutive hours. Ten men were found adequate to perform the whole operation of raising and lowering the post, and adjusting it to its proper position in the cast-iron cylinder. The extreme length of the post over all is nearly forty-five feet. As the crane is not yet completed, we cannot speak of it as a whole; but there cannot be a doubt that it will be a great advantage to the large class of steamers, especially to our yet unrivalled London steamers. And we understand that as soon as it is ready, and disengaged (for the steamer Perth has secured the first turn), a very large steamer from a distance is to be brought to Dundee in order to get in new boilers. In this way, we have no doubt, an ample recompense will be obtained for the great accommodation now to be given for the shipping at the port. Much work, and a considerable amount of shore-dues, may, in consequence of the facilities afforded by the crane, be brought to Dundee, which otherwise would have been lost to it. The testing of this vast machine will be a process of some interest; and we have no doubt the successful result will add to the well earned reputation of Mr. Leslie; and be highly creditable to Mr. Borrie, by whom the work has been executed.—*Dundee Courier.*

Seguin's Animal Gas Apparatus.—In a memoir on the compression of gases, and on the reduction of variable pressures into regular pressure, M. Seguin gives the Academy of Sciences a description of a new pump, with a regulating apparatus, for the compression of gas for illumination obtained from the distillation of animal substances. The pump is so arranged as to give the maximum force at the moment of the course when the gas presents the maximum of resistance by the diminution of its volume; to work in a vertical position without loss of gas, and without the piston being immersed in fluid; and lastly to avoid, by means of a particular mode of transmitting power, the use of guides, which would cause a friction in the piston-rod.

Artesian Wells.—M. Viollet has communicated to the Academy of Sciences the results of the experiments which he has made at Tours, to ascertain the quantity of water supplied by an Artesian well, after some repairs undertaken for the purpose of remedying a considerable diminution which took place in the produce. The repairs executed under the direction of M. Mullot had complete success, and the well now serves to supply motive power for the silk mill of M. Champoiseau. The well, which in July, 1834, immediately after its completion, only supplied 1600 litres per minute to the surface, has since given the following results ascertained by gauging kept up from the 15th to the 23rd of May last.

0·50 metres above the surface	3480 litres per minute.	
4·75	. . .	1620
5·75	. . .	1110

The well having been put into action, and supplying its water from the 23rd of May from a new orifice, situated 5 metres above the surface, I found by gauging, on the 2nd of August, a produce of 1702 litres per minute, instead of the 1620 only, which the orifice at 4·75 metres gave in the 23rd of May. The produce has, since then, still further increased, which progressive increase is attributed by M. Viollet to the alimentary channels being cleared by the rejection of the sand brought to the surface by the water of the well; but it is important, as it leads to the hope that the unfortunate diminution of supply will not again occur. [We cannot entertain the confidence of M. Viollet, but must feel, to some extent, distrustful of wells sunk in sandy strata, which are exposed to many inconveniences.—Ed. C. E. & A. Jour.]

REVIEWS.

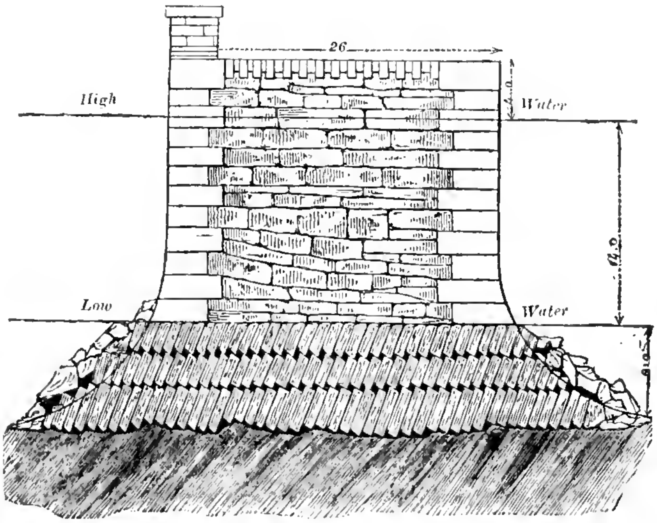
Theory, Practice and Architecture of Bridges. The theory by James Hann, *of King's College, and the practical and architectural treatises by* William Hosking, F.S.A., &c., Vol. I. London: John Weale.

Our present remarks will be confined to Mr. Hughes's paper on the "Foundations of Bridges," as we have previously noticed most of the other articles. Mr. Hughes commences his paper by taking a review of various methods of laying foundations by mean of caissons, next he explains the manner of building bridges on dry land, the stream being afterwards diverted from its old course and made to pass under the new bridge,—he then explains the method of building piers called by the French *encaissement*, practised by Belidor. Afterwards comes the method of laying, in deep water, foundations of piers, bridges, &c., without the aid of a coffer dam. As this portion of the paper will best explain the talents and capacity of its author, we shall give a lengthened extract, accompanied by the wood engravings, liberally furnished to us by the publisher.

The first work of the kind I shall describe was projected by Mr. Telford, and executed under the superintendence of Mr. David Henry, at Ardrossan Harbour, in Ayrshire, N. B.; and as the mass of stones used in the foundation was there set in tolerably regular order under water, without the aid of coffer-dam, or caisson of any kind, there can be no doubt of the same system being equally practicable in many cases of bridge foundations.

The stones at Ardrossan were of very large superficial dimensions, varying from six to ten feet long, and three to five feet wide; they were first held fast by an implement, technically called nippers or devil's claws, and were then lowered by a crane through a depth of six or eight feet of water on to a hard and solid foundation. The blocks were placed end to end, the position of the last stone lowered being found by probing with a slight iron rod; and as soon as each stone was in its place longitudinally, the claws were disengaged, and the stone allowed to rest upon the course below, as seen in fig. 1. The courses were continued entirely through the whole thickness of the pier; and when a sufficient number had been laid to bring the work up to the height of low water spring tides, the whole beeadth was levelled, and all the unequal projections chipped off, in order to prepare a bed for the firs course of dressed masonry. The work then proceeded in the regular manner, consisting of alternate headers and stretchers of properly squared ashlar

Fig. 1.

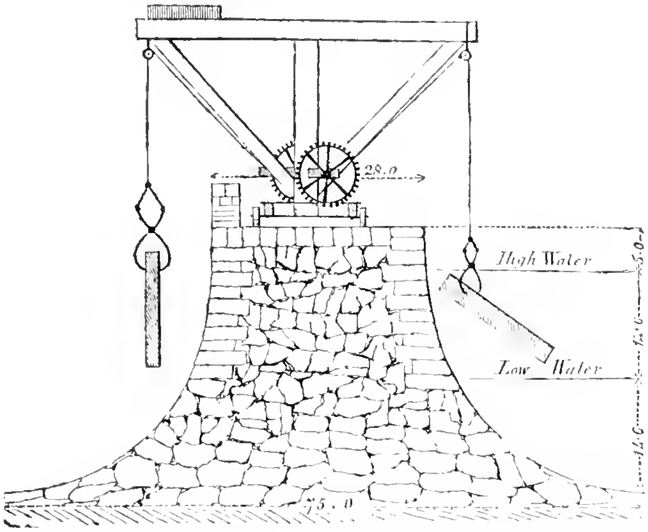


in front, with dry stone hearting of squared scapple dressed rubble inside, and in this way was carried up to the full height required.

When the writer visited this work, in the year 1818, it had been advanced a consideraole distance into the sea; and although parts of it had been exposed to some very heavy storms, neither flaw nor settlement could be discovered in any part of this excellent piece of dry-built masonry.

From an account of some foundations similar to that described above in the recently published life of Mr. Telford, it may be seen that the practice has been much more extensively adopted, and a far bolder attempt carried out by Mr. Gibb, of Aberdeen, than the one acted upon in the other work at Ardrossan. The pier at Aberdeen is extended into the sea, with a breadth at the base of seventy-five feet, the bottom consisting entirely of irregularly shaped masses of stone, which having been conveyed to the spot in boats, were tumbled in by chance to the depth of ten or twelve feet. In the drawings composing the Atlas, which accompanies the life of Mr Telford, the low water mark is shown about fourteen feet above the bottom, and in the narrative of this work by Mr. Gibb, he states, that the bottom under the foundation is nothing better than loose sand and gravel, and that the front ashlar commences at about one foot under low water mark, and is carried up to the top of the pier, which the drawing shows to be about thirty-three feet in height from the bottom to the top. The rise of the tide is shown to be fourteen feet, the breadth of the pier twenty-eight feet, the sides carried up with a slope inwards. Fig. 2, describes the method adopted by Mr. Gibb.

Pier at Aberdeen. Fig. 2.



The author next proceeds to describe an economical method of building the foundations of a pier as practised by Mr. Telford at Inverness, to avoid the expence of erecting a coffer dam. This is well deserving of notice on account of its simplicity, particularly the part explaining the "lewis."

At the site fixed upon for the intended pier, the depth of water, at the lowest spring tides, was never less than four feet, and at ordinary low water five or six feet; the bottom a very hard gravel, united with clay. The whole length of the breast work was about one hundred and sixty feet, and throughout this distance the bottom was dredged out, to the width of eight feet, and depth of two feet, to receive the masonry.

A simple system of piling was however driven previous to founding the masonry. The piling consisted of two bearing piles, twelve feet long, and eight inches diameter, driven down at intervals of twenty feet; and across the heads of these piles, and level with low water mark, cross pieces of elm planking twelve feet long three inches thick, and one foot wide, were fastened with trenails. On the top of these were laid longitudinal half timbers, one foot wide, and six inches deep, secured to the cross pieces and bearing piles by rag bolts, driven into each pile head.

The accompanying sketches, figs. 3 and 4, will amply illustrate the forms and disposition of the timber work in the foundation. In addition to the bearing piles, a row of timber slabs, of inferior quality, was also driven down a few inches into the bottom, at intervals of about ten or twelve inches; these had a spike driven through them, near their heads, and into the longitudinal logs of half timbers; there were merely to answer the purpose of guide timbers, to set the stones by, and to determine the guage or breadth of the work, and were afterwards removed.

The bottom on which the pier was to be founded being now made as level

Fig. 3.

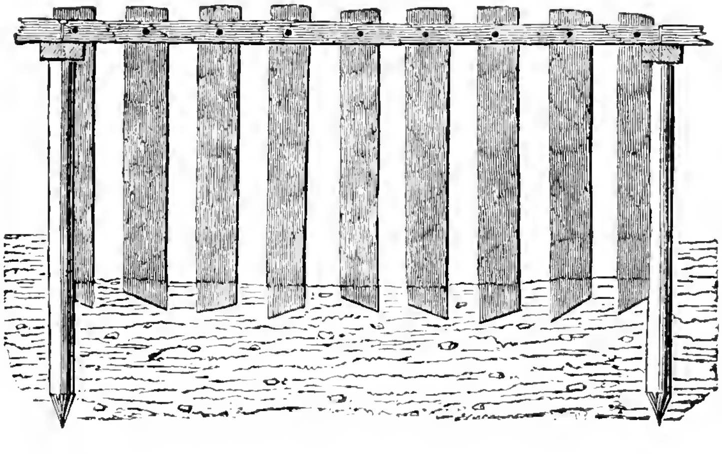


FIG. 4.

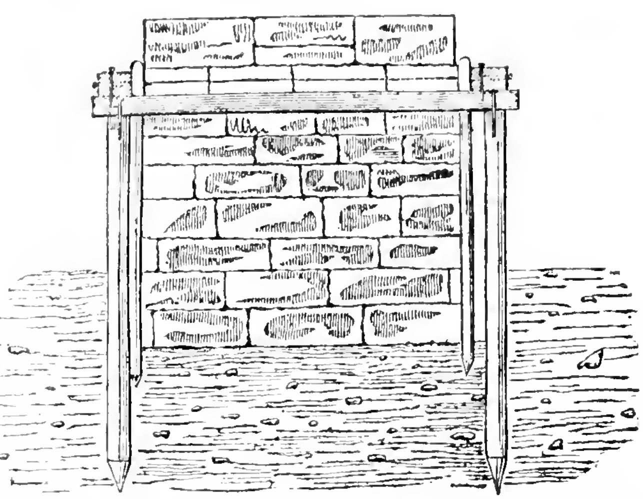

as possible by means of dredging with the common bag and spoon apparatus, the stones were brought to the place in boats, and lowered by a crane, in such a way that as soon as each stone was placed in its proper position the *lewis* could be withdrawn without difficulty.

This will be understood on referring to fig. 5, which represents the lewis fixed in a stone, ready prepared for being lowered through the water into the foundation. The lewis consisted of two pieces of iron B and D, and in order to use it a part of the stone must be cut out, sufficiently wide at top to receive the base of the part B, the base of the opening of the stone being equal to the united width of D and B; A is the chain suspended from the arm of the crane,* and E a small rope or string, of which the end is kept above water, to pull out the rectangular part D of the lewis.

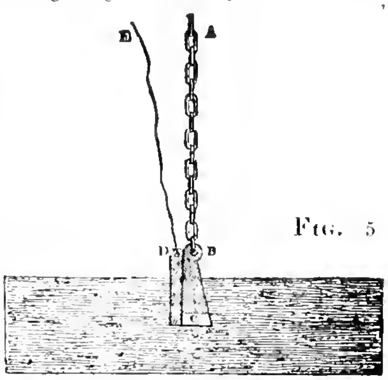

FIG. 5

It is easy to see the method of using this instrument: the piece B is first inserted, and D is then put in to secure it, when it is evident that the heavier the stone may be, provided it be strong enough, the more securely will it be held by the lewis when suspended from the crane. Conceive the stone now to have been lowered through the water, and carefully laid in its proper place in the foundation; the chain from the barrel of the crane is then loosened, and the part B of the lewis being slightly knocked with an iron rod from above, is easily made to drop down into the vacant space C. It is evident that the fastening piece D will then be loose, because between this and B there is a space left equal to the difference between the base of B, and the base of the opening in the stone. D may therefore be drawn out by means of the string E, and B will readily follow on pulling the chain A, and the lewis is again ready to be inserted in another stone.

All the front stones of the foundation were laid with a lewis of this kind, as well as the backing of squared stones, which were previously scapple-dressed at the quarry. The whole of the stones in any one course, for the length of the pier, were laid of equal thicknesses; they ranged from four to seven feet long, and from three to four feet wide. As soon as one course was complete another was laid, and the length of each stone being marked on the longitudinal beams above the piling, it was easy to set them so as to break bond, and the whole process of thus building under water was effected with the utmost regularity, and with less difficulty than could have been anticipated by the most sanguine advocates of the plan.

When all the building was carried up as high as the surface of the lowest water mark of a spring tide, any irregularity on the top was taken off, and the whole surface carefully levelled, and on it the ashlar masonry was commenced and carried up with a vertical batter. This work consisted of stones with picked fronts and chisel-draughts round the edges, the ends, beds, and face, properly squared. The backing was of good common rubble, and the whole being raised to three feet above the highest spring tides, was finished off with a heavy coping, properly dowelled, cramped, and secured with lead.

---

* It is quite evident that by any other mode of suspending the stones excepting that of the lewis, which could be disengaged under water, even an approximation to a close joint could never have been effected in the situation now described.

This work, from its situation, is called the Thorn Bush Pier; the date of its construction was 1815, and up to the present time no appearance of failure or imperfection has been observed.

Mr. Hughes then reverts to the consideration of coffer dams, and points out as good examples the coffer dams of the new Houses of Parliament, and the one constructed at St. Katharine's Dock, both of which, we are happy to say, have been described in the first and second volumes of our journal, accompanied by the specifications. We consider the latter ought at all times, if possible, to accompany the drawings, as they at once convey to the profession the minutiæ of the construction, and of the materials used. As we have so fully explained to our readers the construction of the above works, we shall not avail ourselves of any extracts from the able comments of the author in the paper now before us, but shall proceed at once to the other portion explaining the advantages of building inverted arches. The author recommends, where the bottom is unsound, to cover it entirely over with cross sleepers of Memel logs, and on them to lay a covering of planks closely jointed. In support of this method of construction he cites an example of the late Mr. Rennie, who introduced it for the foundation at the Albion Mills, close to Blackfriar's Bridge. We cannot give our consent to this mode of building, being decidedly averse to the introduction of planking and piling, excepting for hydraulic works when both are constantly under water; we would at all times risk a good bed of concrete over the whole surface as adopted at the Westminster Bridewell, or a broad foundation as adopted by Sir Robert Smirke at the Penitentiary, the latter example is alluded to by the author in a subsequent part of the paper. The marshy nature of the land on which both those buildings were erected, and their present appearance in point of stability clearly show that concrete may be used with safety in almost, if not all situations: we have seen such ill effects of planking for foundations of land buildings, that we dread the very name of it, not only is it liable to rot, but also to be crushed. We should think that the timber forming the bottom of the caisson upon which the piers of Westminster Bridge stand has been crushed full an inch in thickness; here it was of no consequence, as the timber was always under water, and remains to this day sound as on the day when laid down, but there are situations in which the crushing of an inch in thickness may be partial and cause considerable settlements in the building, particularly if there be many openings with arches in the superstructure. The following observations relative to Mr. Telford are well deserving the attention of the junior members of the profession.

Mr. Telford in his practice as an engineer was exceedingly cautious, and never allowed any but his most experienced and confidential assistants to have any thing to do with exploring the foundations of any buildings he was about to erect. This scrutiny into the qualifications of those employed about the foundations extended to the subordinate overseers, and even to the workmen, insomuch that men whose general habits had before passed unnoticed, and whose characters had never been inquired into, did not escape Mr. Telford's observations when set to work in operations connected with the foundations. He was accustomed to examine men so employed whom he thought unsteady, and, if necessary, would reprimand the overseers for employing such men about the foundations in any capacity. It is evident from these precautions that Mr. Telford was well convinced how dangerous it was even to receive a report of the strata from men of careless habits or inefficient knowledge, and that he also knew the consequences which might follow from careless pile-driving, and, in short, from the absence of proper care in all the operations connected with the commencement of an important structure.

In the third division of this paper the author makes some judicious remarks on foundations of sand. Mr. Hughes then proceeds to describe a very strong coffer dam for a river where there is a great depth of water, from this part of the paper containing some excellent instructions, we take the following extract relative to "puddle."

Considering only the two extremes of very hard and very soft plastic clay, it will be found that the former of these, when broken up and thrown in between the piles, will seldom or never form a perfect dam. On the contrary, vacuities will remain between the broken pieces, and it will be found exceedingly difficult to beat down clay of this kind into a body sufficiently firm, compact, and solid to resist the efforts of the water to penetrate through it. If, again, clay of a very soft plastic nature be introduced, it will partially dissolve and combine with the water when thrown into it, so that the space between the piles will be filled with a kind of mud puddle almost in a fluid state, of no greater consistency and no greater capability of keeping out water than mud itself. It is evident therefore that either kind of clay by itself would not answer the purpose intended of forming a solid water-tight puddle. All the clays, when used in a coffer-dam, require a mixture of gravel and sand, or a portion of pounded chalk will be found an excellent material to give solidity to the soft portion of the clay, and to fill the vacuities and interstices which may be expected to exist where the clay is of a hard and lumpy description. However general may be the opinion, it is certain that one more erroneous was never entertained than that clay alone is a proper material to make a good puddle-dam. Clay by itself is subject to great changes, according to the alternations of heat and cold, drought and moisture. In very dry weather, and when exposed for a time to the influence of the sun, all moisture will be extracted; and the clay will invariably crack and separate into a number of irregular fragments, which will never afterwards unite so as to form an adhesive water-tight substance. The difficulty of compressing clay, when placed in a dam of any considerable depth, into a solid mass without hollows has been already noticed. If in addition to this objection we consider the immense weight and pressure of clay so compressed against the piles forming the sides of the dam, and the consequent strain on the piles, which ought only to be employed in resisting the pressure of the water from without, we shall see sufficient reason to decide, on these as well as on other grounds, against the practice of puddling entirely with clay. From the very best information which can be brought to bear on this subject, namely, that derived from long and watchful experience, accompanied by the knowledge that he has himself, as a contractor, lost large sums of money on account of too great a faith in clay puddles, the writer is enabled to speak very positively on the nature of this material, and in addition to the objections already advanced begs to add his own personal observations of the fact that puddles composed entirely of clay have usually bulged, given way, and been found incapable of keeping out the water when of considerable depth, and that in any case a puddle with an admixture of gravel, chalk, and sand will make a safer water-tight dam than clay alone.

The fourth division treats on the value of concrete as a substitute for stone or timber in foundations, and describes the various qualities of lime and sand, and their proportions in which they ought to be used. The author has given some remarks on the defective construction of part of Gloucester Bridge, from the settlement of the wing wall on the Gloucester side which is fractured from its base to the top of the parapet, where, he states, there is an opening nearly three inches wide. We rather suspect that some other settlements have escaped the eye of Mr. Hughes, when we were at Gloucester about two years since, we observed some fractures over the arch which had been stopped up with cement, and instead of the wing walls only having gone down, we consider that the abutment on the Gloucester side has also gone down, or is forced a trifle from its perpendicular position in consequence of the giving way of the wing walls, and has caused the settlements we have named.

Mr. Hughes next explains the causes of settlements in the wing and abutment walls of bridges by using for the backing a puddle of clay; he observes, that the cracks and fissures which attend the drying of clay, when much exposed, are so exceedingly dangerous, as affording lodgement for water to press against the wall, that there is every reason to expect, at some time or other, fractures and dangerous settlements in walls which have been thus backed. We have heard of several instances of bridges constructed on railways, where the abutments and wing walls have been forced out of their places, although built with a considerable batter, to nearly perpendicular, owing to the backing of clay having swelled through additional moisture. Where it is requisite to build retaining walls in clay cuttings, it is necessary if the strata have any dip to build the upper retaining wall thicker than the lower one, and also to give the slopes of cuttings on the upper side a greater declivity than the lower one, as the clay is naturally inclined to slip on its bed.

In the concluding portion of the paper Mr. Hughes has made some very able comments on the principal clauses of a contract deed which the contractor is required to sign; but as we have already so copiously extracted from the paper, we must, in justice to the publisher, resist intruding any farther. With his remarks on the various clauses we fully concur, and we trust that it will not be long before a more equitable spirit breathes through the conditions of a contract. We feel convinced that it is the only way to obtain opulent and respectable contractors to undertake large works, the present stringent clauses throwing the whole onus of the construction on the contractor, and removing all responsibility from the engineer, is a premium for ignorant pretenders to enter the profession, many of whom, probably, have obtained a fine theoretical education, and are able to make very pretty drawings, which they fancy entitle them to the initials C. E. at the end of their names, but which are very far from assuring a sound knowledge of construction.

Before we close our remarks we must allude to the "getting up of the work," the first volume contains 110 engravings beautifully executed, and possessing considerable merit in point of construction, and as examples of bridge building. The letterpress contains 5 papers, No. I. Theory of Bridges, by Mr. Hann; II. Translations from Gauthey; III. Theoretical and Practical papers, by Professor Moseley; IV. A series of papers on the Foundations of Bridges, by Mr. T. Hughes; V. Account of Hutcheson Bridge at Glasgow, by Lawrence Hill, Esq., and the Specification by Mr. Robert Stevenson, of Edinburgh. Most of these papers, as they appeared in numbers, we had occasion to speak of with the highest praise, and we feel much pleasure in finding that the concluding part of the first volume is quite equal to the former. We have no hesitation in saying that it will be one of the most valuable publications which the profession can wish to possess.

Heath's Picturesque Annual for 1840: *Windsor Castle and its Environs*, by Leitch Ritchie, Esq., *with Fifteen Engravings*. London: Longman and Co.

We recommended the preceding volume of this annual, as containing among other illustrations of Versailles, several highly finished architectural interiors,—a class of subjects all the more welcome, because, although exceedingly interesting, they are very rarely treated by the pencil: and the two views of the kind here given, namely, of St. George's Hall and the Waterloo Gallery, only cause us to regret that there should be none of any of the other apartments: not even one of the corridor, or any portion of it, to convey some idea of its architectural character. It certainly was not owing to want of subjects that the choir of St. George's Chapel—the architecture of which, by the by, is sadly disfigured by the barbarous design of the pointed window over the altar, which looks just like Carpenter's Gothic;—was selected as one of the three interiors: while the subject is very well known, having been given in Pyne's Royal Residences, and other publications. We certainly would very gladly have exchanged it for something else. We pass over the other engravings, because although many are executed with great spirit and ability, they are chiefly of scenery in different parts of the Park, and are connected only *remotely* with the Castle, which is removed farther off than we could wish. Yet although architectural subjects generally may not be so popular as landscape scenery, we should imagine that like ourselves, most other persons would not have been displeased had there been a majority of the former class, on this occasion. We should have been grateful too, had the editor in some degree supplied this deficiency by treating at great length of Windsor Castle as it really is at the present day, and entered into some more exact description of the principal apartments, their architecture and decorations. However, as description of that kind does not appear to be by any means the editor's forte, there is less reason to regret that he has been so exceedingly sparing of it. It appears, however, from what is here said that we are likely to obtain a full architectural account of Windsor, it being stated—upon sufficient authority, we presume, that Sir Jeffery Wyattville himself is now preparing a series of drawings and other materials for the purpose.

The view of the Ruins at Virginia Water after a drawing by Harding, is one of the most attractive of the landscape subjects, quite a poetical scene in itself—and one of which we have never before met within any representation; and though the same cannot be said of the view of the Fishing Temple and Lake, that is a very charming composition by the same tasteful artist, and admirably engraved. Most undoubtedly we should have been better gratified had the illustrations been confined entirely to the Castle itself, and to the newer portions of the edifice; but we must also admit that the proprietor had to consult the taste of the purchasers of Annuals. We hope, however, that he will yet bring out some graphic publication expressly devoted to that class of subjects—namely, architectural interiors, of which Versailles and Windsor have furnished some specimens.

Memoir of a Mechanic, being a Sketch of the Life of Timothy Claxton, written by himself, together with Miscellaneous Papers. Boston, United States; G. W. Light, 1839.

This, although published at the same time by a different author, is a kind of American version of the Hints to Mechanics, by Mr. Claxton, but although derived from nearly the same sources, is not quite so interesting. Boston, like Edinburgh, has dubbed itself an Athens, has the same mania for lionizing, and the same want of philosophers for their academic groves. In this emergency they have laid hold of Mr. Claxton, and although they might find a more majestic lion, a more useful one they will not easily discover. Like the works of Franklin, it is a plain, practical manual of advice to the working classes, which instructs in the best way, that of example.

It says much for the literary appetite of Boston that they can devour such a work, and it says still more for them that, knowing how thin-skinned their countrymen generally are, that they should have allowed Mr. Claxton to give free vent to some of his old country prejudices, which we know go so greatly against the grain.

Companion to the Almanac for 1840. London: Knight & Co.

As usual this publication contains a great deal of highly interesting architectural matter, in the way both of descriptions of, and comments upon, new buildings and other improvements, illustrated with several clever wood engravings. Of these latter the subjects are, Mr. Wild's two churches at Blackheath and Southampton, the new church Park Street, Bankside, the Club-house Chambers, Regent Street, and plans, &c. of Mr. Cockerell's new buildings at Cambridge for the Public Libraries, &c. Among those buildings which, although not accompanied with any cuts, come in for a large share of notice and remarks are, Mr. Barry's Reform Club, and Mr. Tattersall's chapel at Dukinfield, as does likewise the new building in Wellington Street, for Bielefeld's Papier Maché Works.

The comments on the plan of the Cambridge Libraries are pertinent, — though, perhaps, the architect may be disposed to prefix an *im* to that epithet—and judicious; for it certainly does appear that the building will be more irregular than even the awkwardness of the site requires: nor that only externally but internally too, because many of the principal apartments will be thrown quite out of square, one of them sloping off instead of being parallel to the opposite one. It is therefore to be hoped that that part of the plan will be reconsidered before it shall be actually begun.

We shall quote only two of the minor paragraphs:

Keswick Church, lately erected by Mr. Salvin, is a stone edifice in the early pointed style, of about the time of Henry II, with a tower, surmounted by a low spire, and a small octagonal building, attached to the south side of the church, for a vestry room. This latter is covered by a very steep, or spire-shaped roof, and forms a very striking feature in the design, to which it imparts a great degree of picturesque variety. This church was commenced by the late John Marshall, Jun., Esq., and has been completed by his widow. It is not capable of containing more than 412 persons, viz., 48 in pews and 364 in free seats. Cost, £6,280.

Darlington Church, another work by the same architect, is very different in design, being a long and low but high-roofed structure, of rather primitive character, with small and plain pointed windows, at irregular intervals, and a square tower (in which is a porch) on the north side. It was built by subscriptions and donations for the sum of £3,254; yet, although the cost is little more than half that of the preceding building, it is capable of accommodating more than double the number of persons, viz., 1,010; 410 in pews and 600 in free sittings."

In a previous part of the volume is a section upon "Railways," containing much statistical information on that subject.

Manchester as it is, with numerous Steel Engravings and a Map. Manchester: Love and Barton.

This is a very useful and interesting little work, descriptive of all the public buildings, institutions, exhibitions, canals, warehouses and manufactories, in short it appears to contain all the information that a visitor may wish for as a guide to Manchester. We select the following extracts to show the nature of the work.

STEAM ENGINE MAKING, AND ENGINEERING.

One of the principal establishments in Manchester, in these departments, is that belonging to William Fairbairn, Esq., situate in Canal-street, Great Ancoats-street. To persons unacquainted with the nature of working in iron, an admission into these works affords, perhaps the most gratifying spectacle which the town can present of its manufactures in this metal. Consequently, almost every person of distinction visiting the town contrives to procure an introduction to the proprietor before leaving it. In this establishment the *heaviest* description of machinery is manufactured, including steam engines, water wheels, locomotive engines, and mill geering. There are from 550 to 600 hands employed in the various departments; and a walk through the extensive premises, in which this great number of men are busily at work, affords a specimen of industry, and an example of practical science, which can scarcely be surpassed. In every direction of the works the utmost *system* prevails, and each mechanic appears to have his peculiar description of work assigned, with the utmost economical subdivision of labour. All is activity, yet without confusion. Smiths, strikers, moulders, millwrights, mechanics, boiler makers, pattern makers, appear to attend to their respective employments with as much regularity as the working of the machinery they assist to construct.

In one department mechanics are employed in building those mighty machines which have augmented so immensely the manufacturing interests of Great Britain, namely, steam engines. All sizes and dimensions are frequently under hand, from the diminutive size of 8 horses power, to the enormous magnitude of 400 horses' power. One of this latter size contains the vast amount of 200 tons or upwards of metal, and is worth, in round numbers, from £5,000 to £6,000.

The process of casting metal is conducted here on a very large scale. Castings of twelve tons weight are by no means uncommon: the beam of a 300 horses' power steam engine weighs that amount. Fly-wheels for engines, and water-wheels, though not cast entire, are immense specimens of heavy castings. A fly-wheel, for an engine of 100 horses' power, measures in diameter twenty-six feet, and weighs about thirty-five tons. In this establishment some of the largest water-wheels ever manufactured, and the heaviest mill-geering have been constructed; one water-wheel, for instance, measuring sixty-two feet in diameter. The average weekly consumption of metal in these works in the process of manufacturing, owing to the quantity of wrought iron used, and the immense bulk of the castings, is 60 tons or upwards, or 3,120 tons annually.

The preparation of patterns,—wood fac-similes of the castings,—is a very costly process. Every piece of machinery, before it can be cast, must be constructed in wood; and these *patterns*, as they are termed, are made to form, in sand, the mould into which the liquid ore is poured. Fifty men are daily employed in making patterns. The patterns, which are part of the proprietor's *stock in trade*, are worth many thousand pounds. After being used, the most important are painted and varnished, and laid carefully aside, in a dry room, to be ready for use when machines may accidentally get broken, or to aid in the construction of new ones. The patterns are made frequently of mahogany.

A most curious machine is employed for the purpose of *planing iron*; and, by means of its aid, iron shavings are stripped off a solid mass of metal, with, apparently, as much ease as if it were wood, and with the greatest regularity and exactness. Not the least interesting department of these works is that appropriated to boiler making. Boilers, for steam engines, are composed of a number of plates of wrought-iron, about ⅜ of an inch in thickness. They are riveted together, with rivets about ¾ of an inch diameter, holes to receive which are punched through the plates, by a powerful, yet simple, machine, with as much facility as if the resistance was mere air. The process of riveting was, on the *old method*, an extremely noisy one; but a new plan, is adopted here, and by it the work is performed silently, and much more efficiently. Some time ago about 50 boiler makers were employed by Mr. Fairbairn. The "struck," as it is termed, because their employer infringed, as they considered, upon their privileges, by introducing a few labourers, not in "The Union," to perform the drudgery connected with the work. On this occurring, Mr. Fairbairn and Mr. Robert Smith invented a machine which superseded the labour of 45 out of the 50 of his boiler makers. The work is performed by the machine much quicker, more systematically, and, as before said, without noise.

LOCOMOTIVE ENGINE AND TOOL-MAKERS.

Under this head may be classed several extensive works, in and about Manchester.* One of the largest is that possessed by Messrs. Nasmyths, Gaskell & Co., situated at Patricroft, four and a half miles distant from Manchester, and immediately adjoining the Liverpool and Manchester Railroad, at that part where it crosses the Bridgewater Canal, which great national work forms the boundary or frontage of the ground on which the above establishment is erected, and which, in consequence, has been named, "The Bridgewater Foundry."

These works have a frontage to the railroad, as well as to the canal, to the extent of 1,050 feet; which circumstance supplies every possible facility for communication, either by land or by water carriage. One of the "stopping stations" of all the second class trains being opposite, persons desirous of visiting these works, can be set down at the entrance gate. The distance in *time*, from Manchester, is only from ten to fifteen minutes.

The above establishment is of very recent erection, having been in existence only about two and a half years. There are employed at present about 300 men: the greater part of whom, together with their families, live in cottages which the proprietors have erected for their accommodation. The situation of these works is not only most admirably adapted for the purposes for which they have been erected, but it also secures, in a great degree, good health to the men employed; for, being surrounded on all sides with green fields, and being, moreover, on the *west* side of Manchester, a very long lease of pure air is secured; a circumstance of no small importance, as regards the health and comfort of the workmen employed.

The whole of this establishment is divided into departments, over each of which a foreman, or a responsible person, is placed, whose duty is not only to see that the men under his superintendence produce good work, but also to endeavour to keep pace with the productive powers of all the other departments. The departments may be thus specified:—The drawing office, where the designs are made out; and the working drawings produced, from which the men are to receive the necessary information. Then come the pattern-makers, whose duty is to make the patterns, or models in wood, which are to be cast in iron or brass: next comes the foundry, and the iron and brass moulders; then the forgers or smiths. The chief part of the produce of these two last named pass on to the turners and planers, who, by means of most powerful and complete machinery, execute all such work on the various articles as require either of these operations; besides which, any holes that are required are at this stage bored, by a great variety of drilling machines, most of which are self-acting. Then come the fitters and filers, who, by means of chisels and files, execute all such work as requires manual labour, and per-

* Messrs. Sharp, Roberts, & Co.'s, Messrs. Peel, Williams, & Co.'s, are among the first in importance.

form such delicate adjustments as require the individual attention of the operative: in conjunction with this department is a class of men called erectors, that is, men who put together the frame-work, and larger parts of most machines, so that the two last departments, as it were, bring together and give the last touches to the objects produced by all the others. A machine having passed through these departments, is now ready for a coat of paint, which having received, it is taken to pieces (after all the parts are marked, so as to enable its being put together when it arrives at its destination), the bright parts are smeared with tallow, and, if required, placed in packing cases, which are then handed over to the foreman of the labourers, who, by means of the crane or railroad, place them in the canal boat or railway waggon.

With a view to secure the greatest amount of convenience for the removal of heavy machinery from one department to another, the entire establishment had been laid out with this object in view; and in order to attain it, what may be called the straight line system has been adopted, that is, the various workshops are all in a line, and so placed, that the greater part of the work, as it passes from one end of the foundry to the other, receives, in succession, each operation which ought to follow the preceding one, so that little carrying backward and forward, or lifting up and down, is required. In the case of heavy parts of machinery, this arrangement is found exceedingly useful. By means of a railroad, laid through, as well as all round the shops,* any casting, however ponderous or massy, may be removed with the greatest care, rapidity, and security. Thus nearly all risk of those frightful accidents, which sometimes occur to the men, is removed. The railroad system is now beginning to be as much attended to, and its advantages felt in concerns of this nature, as it is in the transit of goods and passengers.

Nearly one uniform width is preserved throughout all the workshops of this extensive concern, namely, 70 feet; and the height of each is twenty-one feet to the beam. The total length of shops on the ground floor, already built, amounts, in one line, to nearly 400 feet. There are, besides, four flats of the front building, each twelve feet high, 100 feet long, and 60 feet wide. Into these rooms a perfect flood of light is admitted by very large windows on the side walls, as well as through sky-lights in the roof.

The Foundry occupies one portion of this building, namely, 130 feet by 70 feet, in which great apartment or hall there is not a single dark corner: a point of vast importance where the operations are conducted with a black material, namely, the moulding sand. The iron is melted in one or more of four cupolas, according to the weight of the casting. The cupolas vary from three to six feet in diameter, and when all are in active operation, melt thirty-six tons of iron. The great cauldron, or pot, in which the metal is contained, is placed, during its transit from the furnace, on a carriage, which moves along a railroad in front of the four cupolas; and thus any portion of melted metal can be received and conveyed, with the most surprising rapidity and ease, to any point of the surface of this great hall. These great pots contain, at times, each six or seven tons of melted iron, and, by means of a crane, whose arms sweep every part of the foundry, are handed from place to place as if wholly devoid of weight. The crane posts are two great cast-iron columns, around which the crane arm swings. The columns serve at the same time as supports to the roof, and by proper ties, the strain of such great weights is diffused over the whole building, and each brick made to share the load. The *blast* of air for the furnaces is supplied by a fanner, five feet in diameter, made to revolve at the rate of 1,000 revolutions per minute, the air or blast being conveyed under ground in a brick tunnel, from which it is distributed to each furnace by sheet-iron pipes, varying from three to nine inches, according to the size of the furnace at work at the time.

There are at present fifty-six turning lathes, of all sizes, at work in this establishment, several of which are what is called self-acting,†—that is, the work has only to be placed in the lathe, and the tool set, and the machine does the remainder of the work with unerring accuracy and ease.

Planing machines are extensively used here. The immense power of one of these machines may be imagined, when it is considered that the amount of resistance against the edge of the knife which planes the iron is, in a large machine, as much as thirty tons. This fact leads to the consideration of the hardness of the instrument which has to encounter, for perhaps a day together without becoming inoperative, this immense resistance. By means of this admirable machine every variety of geometrical figure can be produced with the most absolute accuracy—such as the plane, the cylinder, the cone, and the sphere. And as all possible varieties of machinery consist merely of these figures in combination, there is now every facility for producing whatever may be required.

Besides the manufacture of every description of engineers' tools, another branch of business for which this establishment has been erected, is that of locomotive engines, a branch of business which is rapidly acquiring great importance, and which will have few rivals as to magnitude. Lancashire appears to be completely taking the lead in this manufacture, which, from its very nature, can be carried on only on a large scale.

The room occupied by the steam, in a locomotive boiler, is ordinarily equivalent to ten cubic feet. Ten cubic feet of water will produce in steam, when expanded to the density of the atmosphere, as much as would occupy 18,000 feet of space. The steam is confined in the boiler by a pressure three times that of the atmosphere, so that, escaping from its confinement, it expands to three times the space it there occupied.

* Abbreviation of "work-shops."

† "We may here with propriety say a word on the subject of self-acting tools, the more so because it is by means of these admirable adaptions of human skill and intelligence that we are giving to the present age its peculiar and wonderful characteristic, namely, the triumph of mind over matter.

"By whom or when the *slide* principle was first introduced we need not now enquire; suffice it to say that, by means of this principle, a most wonderful substitute has been found for the human hand in the fabrication of almost all parts of mechanism, whether the substance to be operated upon weighs tons or grains. The slide principle is that which enables a child, *or the machine itself*, to operate on masses of metal, and to cut shavings off iron, as it it was deprived of all hardness, and so mathematically correct that even Euclid himself might be the workman! It is by the slide principle that we are enabled to fix a steel cutter into an iron hand, and constrain or cause it to move or slide along the surface of a piece of metal in any required direction, and with the utmost precision. By means of this principle all the practical difficulties hitherto encountered in the extending and improving of machinery generally, were, at one blow, cleared away. By its means the formation of every geometrical figure became a matter of the greatest ease, and a principle of absolute and unerring exactness took the place of manual dexterity.

"The impulse given by the slide principle, to the manufactures of this country, in the construction of machines for forming other machines, can scarcely be imagined. On the application of an unerring principle to *machine-making machinery*—which *tools* may be defined to be—the mechanical energy of Great Britain, sprang forward at once to that supreme station which she now maintains, and which, if her artisans keep pace with the times, she will ever retain."—*Note by a Practical Engineer.*

Architectura Domestica, von Alexis des Chateauneuf. Large 4 London: Ackermann and Co.

Recent circumstances have given this volume additional interest and recommendation, its author having obtained the second premium in the competition for the Royal Exchange, owing to which his name is no longer a stranger to English ears; and it may, perhaps, be worth while to remark that it had actually appeared prior to that event, consequently it was not the distinction he had so obtained which induced M. de Chateauneuf to bring it out in this country. Whatever may have been his motive for publishing it here, we hope he will have no reason to repent having done so, although we dare not flatter him by saying that he could not have selected a better market; because, if the truth may be spoken, there is far less encouragement given to works of this class here in England than on the Continent. However, we hope that M. de C. will find that there are exceptions to the rule, and that his own case is one of them. Still, one inconvenience we suspect has been occasioned by the work having been got up here, namely, that the author has in consequence been obliged to trust too much to others; and although as far as correctness and intelligence of form go, he could not, perhaps, have employed a more able engraver than Mr. T. T. Bury, we must say that delicacy of outline has been carried by him somewhat to excess. The breadth and depth, or rather the fineness of the lines, is so uniform as to produce a general faintness of effect; whereas, variety of line would have given not only greater vigour but distinctness, also to many of the plates. Mr. Bury would have done well to have looked at some of the architectural subjects in Penier's work on decoration; which, independently of their intrinsic interest, captivate the eye at the first glance, by the union of firmness and delicacy, which gives adequate relief to every object. This tameness in the execution of the plates certainly does not affect the designs themselves, otherwise than it exhibits them somewhat to disadvantage, and sometimes is attended with a degree of insipidity that may unluckily chance to be attributed to the subject, instead of the engraver's treatment of it. These remarks, we think, are called for, even in justice to M. de Chateauneuf, for there are one or two designs, which, had they been better expressed, would have been considered of more importance than they are now likely to be.

To come now to matter of the plates, we scruple not to say that although the designs display great inequality, on account of the very great difference of their subjects, some of the designs being for very small and unpretending buildings, while others afforded more than usual scope for invention—they give evidence of real talent and originality. Yet, being nearly all those of buildings executed for private individuals, the author has, in all probability, been more or less checked or thwarted, if not directly by his employers, by circumstances he was obliged to keep in view, and which prevented him from giving free scope to his own taste and imagination. What is most important is, that many excellent ideas and suggestions may be obtained from them. One of the happiest is that shown in plate 5—namely, a perspective interior of a Holstein barn converted into a garden or rustic saloon, and retaining just enough of the original character to show what has been the architect's motive. It might, perhaps, be pursued still farther, and thereby be found to lead to very much more; especially as regards the form of the ceiling, which might either throughout or in the centre compartment of such a room, be carried up higher than the walls, in two inclined planes, following the slope of the large truss brackets supporting the horizontal beams of the ceiling. The style is both well imagined and well kept up, and the whole is exceedingly pleasing, consistent, and harmonious, though obnoxious to objection from those who would indiscriminately proscribe every thing that is not supported by actual precedent, although indulgent enough towards all which is so authorized, no matter how bad it may be in itself. Granting the merit to be equal, or nearly so, in other respects, we should say that a design which brings forward some novelty is the better suited for publication: particularly in works of which the object either is or ought to be to bring forward fresh ideas, and such *motives* of plan or decoration as may be turned to account, by being adopted as a hint, without being either copied or even so treated as to lead at once to the source of it. This has not always been so well attended to as it ought to have been, else we should not meet with so many published designs as we now do, which afford no other instruction than what might just as well be obtained from almost anything else of the same kind. Such, we apprehend, will be found to be the case with the subject following the one we have just been speaking of; which consists of the plan and perspective view of a villa erected near Lubeck, for Dr. Buckholtz; but which we are by no means disposed to receive as earnest of what the author would be capable of producing, if at liberty to abandon himself freely to the impulses of his own taste. Most certainly will not bear comparison with that of an English house of the same size: the arrangement is undoubtedly simple enough, but too simple for either convenience or effect, and would, therefore, have, perhaps, been all the better, had some positive difficulty occurred, which it would have been necessary to combat.

There is no doubt that such difficulty has mainly led to much of the beauty and variety of plan observable in Dr. Abendroth's house at Hamburg, built by the author between the years 1832-6, and which here forms the principal subject of his volume, being illustrated not only by four plans, and elevation, and a section, but by two perspective views, (one of the staircase, the other of a semicircular apartment), but also by several plates of details. The façade of this mansion or *palazzo* is in what may be called a Grecianized Italian style, much of the detail being evidently of the former character, though the composition and its general features stamp it as decidedly belonging to the latter. Although it is *astylar*, or columnless, it is greatly more decorated than almost any specimens of the class we have in London—much more so, in fact, than two which are likely to be quoted as among the very few that can be named at all, viz., Sutherland House, and that of the Duke of Wellington; since both of them are in an exceedingly cold and bald style of architecture, and with a remarkable poverty of feeling about them; and extreme meagerness and flatness of detail. It is, however, in the interior of this mansion that the architect has cheifly manifested his talent, by much happy invention, contrivance, and taste; and a careful study of the plans will show that there is a great deal of effect which is not very apparent upon a cursory inspection of them. So far from complaining that this single subject occupies too many of the plates, we could have wished one or two more had been devoted to it, either as additional sections, or exterior views, one of which ought, of course, to describe the small oblong hexagonal cabinet, with a semicircular alcove occupying the side facing the centre window; which unusual form—so pleasing in itself, and throwing so much variety into the suites of rooms, has been occasioned entirely by the awkwardness of the site, and the disagreeably sharp angle, the two fronts would else make at that corner of the building. The stair-case is exceedingly tasteful, and exhibits what we take to be altogether a novelty—having never before met with, nor heard of, any similar instance, namely, an internal pediment over the colonnade, produced by the ceiling being composed of two inclined planes, each half of which, where they unite at their ridge, is glazed to serve the purpose of a sky-light.

"The great saloon is adorned with casts of Thorwaldsen's frieze of the triumphal entry of Alexander into Babylon, the more valuable because the greater part of the casts were taken from the clay models of the master.

"The colossal busts of the divinities in the niches of the stair-case, are the work of Seigel. The images of the planets and fixed stars of the painted glass ceiling are from the designs of Edwin Specker. The corner cabinet of the principal story is decorated with arabesques, after designs by the same master, painted in encaustic, by Milde. Unhappily, it was too difficult to represent such sportive fancies in their forms and colours in these outline plates."

After making some of the remarks we have done, it would be preposterous in us now to say that the volume consists entirely of the author's best specimens; though it contains much that is of great interest, we are persuaded that M. de Cheteauneuf could render it more valuable; and we hope that either another edition, or anothe collection, will afford him the opportunity of profiting by our criticism; and if our praise has been somewhat qualified, where we have bestowed it has been sincere—and had there been less striking merit in some of the designs, we might, possibly, have thought better of others among them, than we now do.

Euclid's Elements of Plane Geometry, with Explanatory Appendix, and Supplementary Propositions. By W. D. COOLEY, A. B. London: Whittaker and Co., 1840.

Mr. Cooley, in producing this work, seems almost to wish to contradict his own motto, that "there is no royal road to geometry," for following in the steps of Playfair, he has considerably diminished both the volume of the work, as well as the labour of the student. He has carefully gone over the elements, and greatly reduced the amplications and reiterations, which made former editions prolix, and he has, wherever it was possible, substituted the ordinary arithmetical and algebraical signs. As he himself says, without in the slightest degree injuring the work he has reduced to 120 duodecimo pages the Six Books of the Elements.

Prefixed to the Elements are some remarks on the study of mathematics, as valuable for the elegance of their style, as for the correctness of their reasoning. The importance of departing from the ordinary school rate of teaching cannot be too strongly enforced.

At the end of the work are some notes and exercises on the several books, in which Mr. Cooley gives his reasons for inserting a few fanciful definitions of Playfair. To Playfair we are much indebted, but it must not be forgotten that he was often led away by his turn of mind into mere verbiage, making distinctions without a difference.

Outline of the Method of a Conducting Trigonmetrical Survey, by LIEUTENANT FROME, Royal Engineer, F.R.A.S., and A.I.C.E. London: Weale, 1840.

This is the production of one of the Professors in the Military College at Chatham, and supplies a great desideratum in professional literature. Lieutenant Frome is both practically and theoretrically qualified for this task, and has, therefore, produced a work valuable for its own original merits, and for its careful collation of the best authorities. It shows very strongly the mischief of a government system that a man of such experience and capabilities should be only a Lieutenant, waiting like his less talented and less employed brethren for the Procrustean reward of a rise by seniority.

The work is well arranged, and of a high character going into the practical details of the subject much more deeply than its modest title would induce the reader to believe. From a work of this nature it is difficult to make any selection, but we intend at some future period to extract two or three supplementary portions. We must leave it, therefore, to our readers to take our word for the valuable character of Lieutenant Frome's work.

Ornamental Gates, Lodges, Pallisading and Rails of the Royal Parks, &c. Part 1, containing 25 Plates, Edited and Published by JOHN WEALE.

The designs are principally the Park Lodges and Entrance Gates of Regent's Park and Hyde Park—the elaborately enriched gates to the royal entrance of the New Palace, and the gates and railing to the entrance of the Sultan's Palace, at Constantinople. There are also plans of St. James's Park, Kensington Gardens, and Regent's Park. The whole are very delicately and beautifully engraved in outline.

The Guide to Railway Masonry, by PETER NICHOLSON.

This work is a complete treatise on the Oblique Arch, and contains numerous engravings, illustrating the subject. The author has devoted considerable pains in giving every detail by which a working mason may be able to set out any part of the stone work of a bridge with facility.

The Comic Latin Gramar has been sent to us, a work most admirably illustrated. Whether the design be jest or earnest we do not know, but it is likly to be an equal favourite with the elder as well as the juvenile part of the community.

Voltaic Engraving.—Considerable interest has been lately excited in the scientific world by Mr. Spencer's new process of copying medals and other works of art in copper, by the agency of voltaic electricity. It is with great pleasure that we hear that this process is already beginning to be employed in certain of our manufactures, and that thus electricity will soon be numbered amongst the agents employed for practical and useful purposes. In our former account of Mr. Spencer's invention we spoke highly of the merit of the discovery, and the probable uses to which it might be applied: the result has borne out our anticipations. In the manufacture of plated articles and ornaments, it is often desirable to copy ornamental work, such as leaves, flowers, and arabesque mouldings; this is both difficult and expensive, and from these causes often impossible. Mr. Spencer's invention, however, affords a cheap and easy method of performing what is required, and thus, ornaments on rich ancient plate are copied with the greatest perfection and ease, and without injury to the original. The great advantage consisting of the means of obtaining, at very small expense, a fac-simile in copper, of the ornaments required to be copied, which may then be silvered or gilt. In another art, the voltaic process is, we are informed, being successfully introduced. The makers of buttons often require to have two or three of a particular pattern to complete a set of which they have not the die. To take a cast from the button is, for many reasons, inconvenient and objectionable; and the voltaic process, at the cost of a few hours and very little labour or expense, furnishes a perfect fac-simile of the button, which then only requires to be gilt. It has been said that there is a difficulty in obtaining perfect copies, and that the deposited copper is brittle, porous, and full of holes; but whoever will read attentively the process of Mr. Spencer and follow it, must succeed. The cast of medals transmitted to us by Mr. Spencer, and also those made by Mr. E. Solly and Mr. J. Newman, and exhibited lately at the meeting of the Society of Arts, were very pure and compact copper, and the surface was as brilliant and perfect as could be desired. The process, indeed, is simple, and so far from its requiring, as is generally supposed, either expensive and complicated apparatus, or deep scientific knowledge, nothing can be more easy, as the observance of a few rules renders the success of the process quite certain, and, as regards the expense of the apparatus, the whole of it may be easily procured for a few pence.—*Athenæum.*

LAW PROCEEDINGS.

THE CYCLOIDAL PADDLE-WHEEL.

Mr. Galloway's patent right, which has been disputed ever since the patent was granted, was brought on for trial in the Court of Common Pleas, on Friday and Saturday, November 29 and 30, before Lord Chief Justice Tindal, *and a Special Jury; it occupied the Court two days.*

GALLOWAY AND ANOTHER V. BLEADEN.

The case on the part of the plaintiffs was that Mr. Galloway had invented an improved paddle-wheel for propelling steam-vessels, for which he obtained a patent on the 18th of August, 1835. The invention consisted in a division of the floats into segments, and so arranged in a cycloidal curve as to cause all the five or six segments into which each float was divided to enter the water at the same time, and at such an angle as most diminished the shock occasioned to the vessel by each stroke of the paddle; whilst the segments, when the float reached a vertical position in the water, became joined together as it were, so as to present an undivided surface to the water, and so increase the power of propulsion; and lastly, the float, when passing out of a vertical position, by becoming again divided, offered less resistance to the back water, and, consequently, less retarded the speed of the vessel than if undivided. The action was brought against the defendant, as secretary to the Commercial Steam-packet Company, for an infringement of this patent; to which he pleaded, in addition to the general issue of not guilty, that the invention was not new, as it had already been discovered and used by Mr. Field in 1833; and that the specification was not sufficiently intelligible to render the invention of general utility to the public. Several models illustrative of the alleged invention, were produced, and a comparison made between them and models of the wheels of two of the defendant's vessels, the Grand Turk and the Chieftain, to show that the latter were made upon the principle of the plaintiff's specification. Witnesses were also produced to prove that workmen of competent skill could make the patent wheels from the information contained in the specification, and that the improvement in question was not known in the trade previously to the date of the plaintiff's patent.

The defendant's counsel relied mainly on the ground that the invention had been discovered and used long before the date of Mr. Galloway's patent by Mr. Field, of the firm of Maudslay and Field; and that gentleman, being called as a witness, stated that in 1833 he constructed a wheel on the improved principle now in question, which, upon application to the Lords of the Admiralty, he obtained a promise from them that he should have an opportunity of trying upon the first vessel that came to be prepared; that opportunity, however, was never afforded him, but he made an experiment upon a steam-boat, called "The Endeavour," plying between London and Richmond, by substituting one of his improved wheels (of which a model was produced in court) for one of the Endeavour's wheels. At the end of six weeks, however, the new wheel was removed and the old wheel replaced; because, according to the statement of the captain, the boiler was not large enough for the machinery to work it properly. In that same year he entered a *caveat* at the Patent-office; and in 1835 he made a great number of experiments on the subject at his manufactory; but it was not until the spring of 1836 that he fitted up a vessel called the Dover castle with wheels upon the improved principle, which were similar to the wheel tried upon the Endeavour in 1833.

The defendants, it was urged, had twice acknowledged the plaintiff's patent right, having on one occasion purchased their patent wheels for one of their vessels, and on another, in 1837, paid them 50*l.* for a licence to use their specification in constructing wheels for them.

The Lord Chief Justice summed up the case to the jury, and left three questions for their decision; namely, whether there had been any infringement of the plaintiff's patent by the defendants: whether the invention was new and unused at the date of the plaintiff's patent; and whether the specification was sufficient. With respect to the principal question, as to whether or not the invention was new, the mere fact of a series of experiments having been prosecuted previously to the attainment of the object to which they were directed, could not prevent another inventor from availing himself of the experiments, and then adding the final link which was necessary to bring them to a successful issue. If, therefore, the jury thought that up to the month of August, 1835, the date of the plaintiff's patent, all that Mr. Field had done rested in experiments, those experiments afforded no ground for disturbing the plaintiff's patent, and in that case their verdict should be for the plaintiffs.

One of the jury wished to ascertain whether the wheel tried on the Endeavour was on the principle of the cycloidal curve; or, if the model of it were not in evidence, whether it might not be examined and compared with the original by some competent person.

This question gave rise to some discussion between counsel: ultimately,

The learned Judge said that, as the person who had made the model was not present, he could not allow it to go before the jury.

The jury then returned a verdict in favour of the plaintiffs, with nominal damages.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ARCHITECTURAL SOCIETY.

INSTITUTED A.D. 1831—SESSION 1839-1840.

5th Nov., 1839.—William Tite, *Esq., President, in the Chair.*

This evening's meeting, the commencement of the session, was devoted to a conversazione. It was very fully attended. The Secretary read the report of the committee. The President read a highly interesting paper "on the sculptured writings found on the architecture of the Egyptians, with a notice of the discoveries which led to their being deciphered."

The attention of the meeting was directed to the several works of art which were about the room—noticing more particularly various models in terra-cotta, from Messrs. Sollin, Monton, and Co.'s establishment, of the Strand; also a model of an Egyptian obelisk in black marble, together with other models of buildings, &c. Some original sketches by Mr. George Moore; portfolios of prints, by Hawkins and others.

Report of the Committee.

Gentlemen—This evening being the opening conversazioné of the session, it may naturally be expected by the visitors and members who have kindly favoured us with their attendance, that the Committee should state the views they, on behalf of the Society, intend to adopt during the present session, and at the ensuing evening meetings; and they trust that the suggestions which have been offered, and which they propose to adopt for the further carrying out of the objects of the Society may produce an increased interest in their evening meetings, and may meet with the concurrence and personal exertions of the members generally for their fulfilment.

The Committee first remark that they have been successful in securing the assistance of Messrs. Addams and E. W. Braley, jun., (as Professors) to deliver lectures at the monthly meetings, and that on the intermediate evenings of meetings they have procured the promise, on the part of several of their own members, to deliver lectures, or otherwise to read papers having reference to matters of architectural practice and interest, the subjects of which, in all cases, it is proposed should be announced at the previous evening meeting.

Secondly—the Committee considering that this mode of instruction (by lectures) is provided, more particularly for their class of Student Members, propose, as a means whereby these advantages may be made the more available to the interest of that class, that the Student Members should take notes of the several Professors' lectures, and as a stimulus to a due attention to this portion of the benefits offered to them by this institution, have determined that the subject for the prize usually given for the best essay should be "The best fairly transcribed notes of the Professors' lectures."

And while on the subject of prizes, the Committee have the pleasure to announce that they have received the list of the subjects from the Sketching Committee, for which the premiums will be awarded to the class of Student Members, at the close of the present session.

The prizes to be awarded are—in the first class, design, a pair of silver compasses; second class, drawing, Chambers's Civil Architecture (Gwilt's edition); third class 5th volume of Britton's Antiquities. Beside these prizes, which are given by the Society, the Committee have the pleasure to announce that Mr. George Mair has signified his intention to award the usual prize, entitled George Mair's prize, to be given to that student who produces the greatest number of the most approved sketches from given subjects; the sketches to be made in accordance with the directions of the Sketching Committee.

FIRST PRIZE.

The subject for the design is a concert room, with the entrance, vestibule, and cloak rooms—the length of the concert room to be 80 feet, with a gallery at one end. The orchestra to consist of an isolated raised platform on the ground floor.

The style to be either the Greek or Roman architecture.

The drawings to consist of plan, longitudinal, and transverse sections, front and side elevations, to a scale of 1-6th of an inch to a foot; to be accompanied by a prespective view, and the drawings to be finished in Indian ink, or Sepia

SECOND PRIZE.

The subject for the measured drawings is the colonade to Burlington House.

The drawings to consist of the plan and elevation to the scale of 1-6th of an inch to a foot, with the plan and elevation of one compartment to the scale of ½ an inch to a foot, and details of the order ½ the real size.

The whole of the prizes will be inscribed.

The Committee, not unmindful of the advantages and encouragement the Society receive from the Amateur Members, beg to state they have determined to extend the privileges of that class of members, and that those gentlemen may henceforth, in addition to their former privileges, also have reference to, and the use of, the Society's library and documents at all times of the day, without any restriction; and the Committee trust that this arrangement, which places their privileges on a level with those of the members themselves, so far as the use of the Society's rooms is concerned, may meet the views and wishes of that portion of their members.

In conclusion, the Committee have the pleasure to remark that during the recess several additions have been made, both to the library and museum, and it is hoped that, under the able counsel of their excellent President, the united co-operation of the members themselves, and the flattering support elicited from the attendance of the visitors, that the Architectural Society may have the gratification of finding that the meetings of this session may be as advantageously and as satisfactorily concluded as those of its former sessions.

19*th Nov.*—WILLIAM TITE, *Esq., President in the Chair.*

Mr. BLYTH read a paper on commemorative monuments.

The President announced that Mr. John Blyth (Vice-President) had communicated his intention to give a prize of the value of five guineas for the best drawing of a plaster cast of the human figure, from some specimen in the possession of the Society. The prize to be awarded at the close of the session, and to be described accordingly.

At the solicitation of the student members, the President announced the subjects which had been selected for the prizes, and the resolutions passed last session, assigning the qualifications for the competitors for the prizes were referred to, and read as follows:—"That no student shall be allowed to compete for either of the prizes awarded by the society, who shall have completed his articles, and that the society only award the prizes to students under articles."

Also, "That the same regulation do apply to any private prize, which may be offered for the further encouragement of the class of student members."

3*rd December*, 1839.—WILLIAM TITE, *Esq., President, in the Chair.*

The President gave notice that the subject selected for Mr. Blyth's prize was the figure of "the Atlas." The figure to be drawn 18 inches high, and to be shaded in lines with pencil or ink.

The meeting was then favoured by a very interesting and instructive lecture by Mr. Hemming, the subject of which was "Iron."

17*th December*, 1839.—WILLIAM TITE, *Esq., President, in the chair.*

The President gave notice that the Hon. C. Cavendish had given his assent for the students to measure the colonnade of Burlington House; and that, by the obtaining of which the committee were enabled to complete the list of subjects for the prizes to be delivered at the close of the session.

The President read the list of subjects as prepared by the committee, together with the rules and regulations to be observed by the students competing for the same. The list of subjects, &c., was ordered to be hung up in the society's room.

The President announced a donation from the Architectural Society of Berlin of the third volume of the Architects' Album, published by that body.

Mr. Addams delivered a lecture "On the strength of beams to resist pressure and impact." He referred to iron as well as wood; and in the course of the lecture gave some excellent tables, whereby an easy calculation might be made as to the weight any iron beam would carry.

Mr. Pocock explained to the meeting a new material he had manufactured for the purpose of roofing in lieu of slating, &c., a specimen of which was lying upon the table.

STEAM NAVIGATION.

THE 'CYCLOPS' STEAM ENGINE.

ON Friday the 13th of December, this splendid vessel left her moorings at Blackwall, for a trial trip down the river, and to proceed to Sheerness to take in her guns and equipments. This being the largest steam frigate in the world excited much attention, and throughout her passage down the river, was an object of great curiosity and admiration.

The trial was made under the directions of the Lords of the Admiralty and their officers, several of whom were on board, viz., Sir C. Adam, the Secretary of the Admiralty Mr. Moore O'Ferrall, Sir E. Parry, Sir William Symonds, Captain Nott, Captain Austin, &c. &c.

Her performance was most excellent, the speed was found to be about 10 knots, or 11½ miles, her engines working 21 strokes; and it was universally remarked that there was an entire absence of the unpleasant tremulous motion so generally found in other steamers.

After proceeding close to the Nore Light, she turned and met the "Fearless" Admiralty steamer, which accompanied her down, and their Lordships embarked in that vessel to return to Woolwich, while the "Cyclops" proceeded up the Medway, and made fast to the buoy off Sheerness Dock-yard.

This vessel was planned by Sir William Symonds, and built under his immediate superintendance at Pembroke dock-yard; she combines in a most eminent degree the qualities of both sailing and steaming, together with such improvements as have suggested themselves to her designer from the experience of the "Gorgon."

She is propelled by two engines of 160 horse power each, made by Messrs. J. & S. Seaward and Capel, on the new principle adopted by them, by which they dispense with the large cast-iron side frames and sway beams, the cross heads, side rods, &c., &c., and thus bring the weights of these engines to 70 tons less than they would have been, had they been made on the common beam principle; and thereby also effect a very important saving of space in the length of the engine room. These engines are fitted with a contrivance (which is protected by patent) for warming the feed water on its passage to the boiler, by causing it to pass through a number of copper pipes around which the spent steam from the cylinder circulates, on its way to the condenser; by which means the temperature of the feed water is elevated about 60 degrees above the usual temperature, at which it enters a boiler, and a saving effected in the consumption of fuel of seven per cent.

There are four copper boilers for supplying the above with steam, made entirely of copper, and placed in pairs, back to back, with a fore and aft stoke hole; these boilers are clothed on the system first used by Messrs. J. and S. Seaward and Capel, and since introduced into the navy for Her Majesty's steam ships, for the prevention of the radiation of heat; the advantages of which were evident in the surprising coolness of the engine room. A barometer placed against the side of the boilers only rose to 68°, and another in the stoke-hole to only 72°.

The boilers are fitted with a patent apparatus for detecting and indicating the state of saltness of the water in the boiler; and also with a receiver and apparatus for blowing out, when the time for that operation has arrived; by means of which all danger from salting the boiler, or blowing out the water too low, is entirely obviated; and the boiler may be worked as long with salt water as with fresh.

There are coal-boxes placed on each side of the vessel the whole length of the engine room, and holding when full about 450 tons of coals. The consumption of fuel by actual weight (the coals being weighed during the trial) was 17 cwt. per hour, equal to 6 lbs. of coal per horse per hour.

The "Cyclops" is commissioned by Post Captain Austin, late of the Medea, being the only steam frigate in the navy besides the "Gorgon," of that rank. Her engine room crew will consist of four engineers, twelve stokers, and four coal trimmers.—The actual number of hands including officers and a lieutenant's party of marines, will be two hundred and ten men.

Her dimensions are as follows:—

	Feet.	In.
Extreme length - - - - - - -	217	9
Length of upper deck - - - - - -	195	2
Width across paddle-boxes - - - - -	57	0
Length of engine room - - - - - -	62	0
Width of beam - - - - - - -	38	0
Depth of hold - - - - - - -	23	0
Engines—Diameter of cylinder - - - - -	0	64
Length of stroke - - - - -	5	6
Diameter of paddle-wheel - - - -	26	0
Width of wheel - - - - -	8	0

Weight of engines, boilers and water 280 tons.

Weight of coals for 25 days consumption, 450 tons.

Draught of water with all her guns, ammunition, engines, coals and stores for six months, 16 feet 6 inches.

Tonnage, 1,200 tons.—Power of engines, 320 horses.

The armament of the "Cyclops" will consist of—on the upper deck two 98 pounders; one at the stem, and one at the stern.—Four 48 pounders.

On the gun-deck, sixteen long 32 pounders.

RUSSIAN WAR STEAMER, "PYLADES," AND "THE SONS OF THE THAMES."

This vessel is the last of three which were ordered for the Russian government, and of which the two others have already proceeded to their destination. She went down the river on Wednesday the 18th ultimo, on an experimental trip to Gravesend, accompanied by the Russian Consul and a large party invited by Messrs. Miller and Ravenhill, the engineers who manufactured her machinery, to witness this first trial of her engines. we repaired to Blackwall a little before 11 o'clock (the intended hour of departure), and found that the Pylades had not yet left the docks, and that some time would still elapse before she could be out into the river, in consequence of a large vessel being then on the point of entering the docks. This delay afforded us an opportunity of observing the form of the steamer's hull, which was built by Mr. Pitcher, from drawings by Mr. Ditchburn, to whose talent as a naval architect, the model, if we may judge from the part which appears above water, does great credit.

During this time our attention was directed to a small iron steam-boat, built by Mr. Ditchburn, and fitted with a pair of engines of 28 horse power each, by Messrs. Miller and Ravenhill. She was also going down to Gravesend on her first trial, and while waiting for the Pylades she made several trips in front of the dock entrance to the admiration of all present. She was evidently going at a great speed, but seemed at the same time to cleave the water with such ease as to cause no disturbance whatever in the fluid for there was neither spray nor any perceptible wave against her bows, which speaks strongly for the correctness of the principles followed by Mr. Ditchburn in laying off her lines.

As soon as the Pylades could be got out of the docks, which was not until about 12 o'clock, we proceeded down the river, but owing to some little adjustments which it was discovered were still required to be made in the engines, in order to allow them to work up to their power, the performance was not so good as could be wished, notwithstanding which the engines worked very smoothly, causing little or no vibration in the vessel. The time of running the measured mile at Long Reach was noted on our way down with the tide, but against a rather strong head wind: the distance was performed in 5 min. 47 sec., which gives a speed of nearly $10\frac{3}{4}$ miles an hour over the ground. To ascertain the rate through the water it would be necessary either to deduct or eliminate the velocity of the tide; but, as the engines were not working up to their speed, it was not considered worth while to make the experiment against the tide, so we went on to Gravesend, where we arrived a little before 2 o'clock, and found the "Sons of the Thames" waiting for us. As it had been arranged that the whole party should return to Blackwall on board that boat, she was brought along side of the Pylades, and took the company on board, by which time it was 20 minutes past 2 o'clock; we then started, the Planet, belonging to the Star Company, having left the pier a quarter of an hour before. In the course of one hour we overtook her, and, having gone a little farther, we put about and returned some distance to take a gentleman on board, and passed the Planet again before we arrived at Blackwall, having in the mean time gone completely round her. It is calculated that, in order to do this, we must have been going at the rate of $13\frac{1}{2}$ to 14 miles an hour through the water. This comparative speed with the Planet is the more astonishing as the "Sons of the Thames" has two engines of only 28 horse power each, whilst the Planet has two engines of 40 horse power each.

It may not perhaps be generally known that the iron steam boat, the Orwell, now running between London and Ipswich, which we believe equals, or even excels the "Sons of the Thames" in speed, was also fitted with engines by Messrs. Miller, Ravenhill and Co., and built by Messrs. Ditchburn and Co., so that we may confidently look forward to the time (which we believe not to be far distant), when the speed of our steamers on the Thames shall not only come up to, but even exceed that said to be attained in America, and that with a comparatively small expenditure of power; for if it is not notorious, it is at least known in this country, that the power put into the American steam boats is most gigantic.

New Iron Steamer.—On Saturday the 7th ult., the iron steamer "Enterprise," built and fitted out by Mr. Borrie, of the Tay Foundry, started on a trial trip to New burgh. The model of the hull is certainly beautiful, and at first sight any one must be of opinion that the elements of form calculated to promote rapid sailing are possessed by the "Enterprise" in a very eminent degree. The entrance and runs are very sharp, which, united with the great bearing in the floors render the vessel buoyant, and secure an easy passage through the water. The anticipations formed of her speed were fully realized. She sailed a measured distance of four miles marked on the shore in the space of 12 minutes. The tide was in her favour, and admitting it to have been running at the rate of four miles an hour (although it was under that rate) would make the actual distance performed by her over the ground at the rate of 16 miles an hour, a speed that has not hitherto been attained by any steamer. It may be remarked that this speed is not so much attributable to the great power of the engines as to the form of that part of the hull immersed in the water; and indeed Mr. Borrie states. that in making his calculation for procuring a given speed, he placed a greater reliance on lessening the resistance that would be experienced by the vessel in passing through the water for obtaining a high velocity, than by dependence on great propelling power. In this he has decidedly succeeded, as the result amply proves. The vessel measures 280 tons, and has two engines of 35 horse power each. which is a power much less in proportion to the tonnage than that of many steamers which would not sail 10 miles an hour, and at the same time having a sectional area of resistance not greater than that of the "Enterprise." A striking feature in the "Enterprise" is the consumption of smoke. This is effected by a plain and very simple contrivance in the interior of the furnace. The furnace bars instead of being straight are curved on the upper surface. and are so adjusted in the furnaces as to form a very acute angle with the front of the boiler at the furnace doors, whilst towards the posterior extremities they are horizontal, in other respects they are similar to those in general use The furnace covers deflect about 18 inches into the furnaces, within two feet of the inner end, which forms a water chamber. The distance between the upper surface of the coals when the furnaces are fully charged, and the under surface of the deflector, is about six inches. The coals for every new feed being deposited in the anterior part of the furnace, which is fully two-thirds longer than the posterior part or space behind the deflector, it follows that the coals before requiring to be pushed back into the space behind the deflector must have become very highly ignited and the component parts which cause the emission of smoke entirely disappear. Then the posterior fire chamber being always charged with fuel which only emits a pure and intense flame. the smoke arising from the coals in the anterior chamber having to pass underneath the deflector come immediately into contact with the flame in the posterior chamber, and having to pass through in its way to the flues is exposed to its most intense action, whereby it is immediately consumed. The dimensions of the "Enterprise" are,—Length of keel, 116 feet; breadth of beam, 21 feet; depth of hold, 8 feet.—*Dundee Courier.*

Steam Navigation across the Atlantic.—Early next spring, and during the year, there will be placed on the several lines three new steamers to ply between England and New York, and Mr. Cunard's steamers to Boston, by the way of Halifax, will go into operation. Two of the three, the *New York* and *President*—the former for the Transatlantic Company, and the latter for the British Queen Association—are nearly ready for launching: and the *New York* will probably leave England in April or May, and the *President* in Jun or July. The third is now building for the Great Western Company, and will be constructed of iron. She will not be ready before next September or October. These, together with Mr. Cunard's, which will commence running in May next, will keep open a free communication with Europe without the aid of "windy" vessels. Together, they will form a line so that there will be two departures from England and two from the United States every month. In addition to these, the keel of another steam ship, to be of 1,150 tons, and 450 horse-power, has already been laid for the Transatlantic Steam Company, to run in connection with Liverpool and New York. She will not be finished before the spring of 1841; and also by that time there will be two large and splendid steamers ready to start from the Clyde, and run across to New York. With steamers, as with sailing packets, the builders improve with every new vessels. It it said by those who have seen the plans of the new steamers, that the improvements adopted will place them on a par with our packet-ships in point of comfort, &c. The Atlantic will soon be as thickly dotted with steam-ships as with sailing vessels.—*New York paper.*

Port of Fleetwood.—The commissioners from the Court of Exchequer, sent down for the purpose of surveying and setting out the boundaries of the Port of Fleetwood, finished their task yesterday se'nnight. They commenced on the previous Monday to survey the coasts and creeks between Lancaster and Preston, and determined the limits of the port as follow:—To commence at a run of water called the Hundred End, about two miles to the west of Hesketh Bank, continuing up to Preston, thence along the coast on the north side of the river to Lytham, round the coast to Blackpool, and on to Fleetwood; thence to the river Broadfleet, four miles from Sea Dyke, including both sides of the Wyre, and the river Broadfleet.—*Preston Pilot.*

The British Queen is not intended to be started for New York on the first of January, as previously advertised, the proprietors being of opinion that one very serious impediment to the speed of the vessel is in the interior construction of the paddle-boxes; and, accordingly, a new description of paddle, called "The Reefing Paddle," is about to be substituted—this new paddle being the invention of the celebrated Mr. Samuel Hall.—*Midland Counties Herald.*

ENGINEERING WORKS.

The Hull Dock company are about applying to Parliament for making an extensive dock and entrance for the large class of steam boats, &c. on the east side of the river Hull.

Woolwich Dock-yard.—In the November number, we inserted a paragraph from the "Times," stating that the new dry dock, making at Woolwich, and other works, were under the charge of Lt. Dennison; upon enquiry, we find that the new dry dock now on hand at the east end of the yard, is being constructed under the direction and superintendance of Mr. Walker, by Messrs. Grissell and Peto.

New Pier at Margate.—This pier, which is intended to rival that of Ramsgate, as a refuge harbour for her Majesty's steam-vessels, &c., is, we hear, to commence at the Wayland and Fulsam rocks, from the facility arising from their receiving the piers on a foundation of solid chalk, extending 1000 feet from the gateway to the sea at Westbrook. The second point, opposite the fort, next the East Cliff, is intended to be 500 feet, leaving an opening for vessels to the extent of 400 feet.—*Advertiser.*

Cowes.—It is now expected that Sir John Rennie's plan for deepening the Medina will be carried into execution. A spacious town-quay will also be erected, and it is rumoured that the members of the Royal Yacht Squadron are about removing their rendezvous from this place to the anchorage off Norris, on which estate a splendid club-house is to be built for the accommodation of its members.—*Hampshire Telegraph.*

Proposed new road from Perth to Elgin.—A meeting was lately held at Elgin on this important subject, when a number of proprietors and gentlemen of the town attended, including the Duke of Richmond. Mr. A. Mitchell, civil engineer, Perth, attended with a report he had drawn up on the subject, as to the probable expense, &c. of the new line. The estimates, framed on a minute survey he calculated would not exceed £23,000. The probable revenue to be derived from tolls, Mr. Mitchell estimated in all at £1530. After Mr. Mitchell's statement and report, the meeting passed a series of resolutions, appointing a committee to prepare a memorial to Government soliciting pecuniary assistance, as also the aid of the members of Parliament connected with the northern counties and burghs.

Shoreham Harbour.—The new pier at the entrance of the harbour has been carried a considerable distance into the sea, and though it will doubtless improve the harbour, it checks the travelling on the beach between Brighton, and in case of high tides may occasion considerable inconvenience.—*Brighton Herald.*

Teignmouth Bridge, Devon.—It may be fresh in the recollection of our readers that a very considerable portion of this bridge suddenly fell in June 1838, caused by the destruction of the timber piles from the ravages of the worm. The restoration was only commenced in the early part of the autumn, by direction of Her Majesty's Commissioners for Exchequer Bill Loans, from the plans of Messrs. Walker and Burges. If we may judge from the progress already made, and the number of workmen employed, there is every prospect of the bridge being again made passable to the public in the course of a couple of months. We regret having omitted noticing this work before, as we attach greater interest to works of this description (after failure) than in the first construction. We hope again to refer to this subject with a more detailed account of the plans adopted.

PROGRESS OF RAILWAYS.

Grand Junction Railway.—A good deal of inconvenience and trouble were occasioned a few days ago to the passengers on the railway, and the servants of the company, by "a slip" or fall of a great portion of bank, about seven miles on this side Birmingham. At that point there is a very deep cutting, the bank on one side of which, having been loosened by the late incessant rains, was shaken down by the passing of the six o'clock train, on Saturday morning last. The engine was partially covered by the mass of earth, but providentially no injury was sustained by any of the passengers. Another engine was obtained to forward the train, which was, of course, delayed considerably beyond its usual time, as were also the other trains which followed; the passengers and luggage having to be transferred from one train to another before they could proceed, both lines of rails being entirely covered with a vast quantity of earth. We understand that the line was not cleared so as to allow of the passage of trains until Monday.

Great Western Railway.—The works of this railway, between Dudast and Farringdon, are so far advanced, that we understand the directors confidently expect to open the line nearly thirty miles beyond Reading, about the same time as to that town itself; in which case, upwards of sixty miles of the London division will be open for public use in the spring, and the line between Bristol and Bath at the same time.

North Midland Railway.—The contracts for the Eckington, Chesterfield, and South Wingfield stations have been let to the following parties:—Eckington, to Messrs. Smith and Brown, of Sheffield; Chesterfield, to Messrs. Leather and Waring; South Wingfield, to Mr. Radford, of Alfreton. Total amount, £7,000. The Belper contract is not yet let.—*Derby Reporter.*

Hull and Selby Railway.—On this line all the works continue to be prosecuted as rapidly as the very unfavourable weather allows. About two-thirds of the whole of the iron work of the superstructure of the bridge over the river Ouse, at Selby, are now on the spot, and the men are busily engaged in fixing it; the whole of the ironwork of the bridge over the river Derwent, near Wressel Castle, has arrived there, and two of the ribs are fixed across the river, the greatest portion of the entire length of the railway is ballasted, and the contractors are busily engaged in laying the permanent way. We understand that it is highly probable the railway will be completed by Midsummer next, and that in the course of the year, there will be a complete railway communication between Hull and London.—*Midland Counties Herald.*

Glasgow and Ayrshire Railway.—It is truly gratifying to find that the highest anticipations formed of the success of this railway, promise to be fully realized, as a traffic on the limited portion of the line already opened is being created, far more extensive than the most sanguine could have expected. Indeed, this undertaking affords a more than ordinary illustration of the fact, that facility of communication secures traffic for itself. Before the line was opened to Irvine, the intercourse between these places was so very limited, that public accommodation did not demand more than a one horse coach, thrice a week. Now, however, that railway coaches run to and from Irvine thrice a day, and there is a coach stationed at Irvine to carry forward passengers to Glasgow, this route has become quite a thoroughfare. And well do the shareholders of the Glasgow and Ayrshire Railway merit so flattering a prospect of the success of a speculation fraught with such inspeakable advantages to the west of Scotland. The recent return of the number of passengers that have travelled from Ayr to Irvine, during the three months ending the 5th current, (36,832) must give them great confidence, that when the entire line to Glasgow is opened, the traffic upon it will greatly exceed the estimate laid before parliament. Indeed, we believe that the parliamentary proof went no farther than to warrant the *annual* traffic in passengers of 32,000, 4,832 less than have already travelled in three months! The line from Irvine to Kilwinning being now on the eve of completion, will be opened in January next, when a large increase of traffic must necessarily follow, from the surrounding populous districts, including the towns of Dalry, Kilbirnie, Beith, Stevenson, Saltcoats, Ardrossan, &c. The entire line to Glasgow, as is now pretty well known, is expected to be opened in June, 1840.—*Ayr Advertiser.*

North Midland Railway.—The Leeds station, or terminus, we understand, is to be let by contract to-morrow. The Belper station, we hear, is to be built by Hugh M'Intosh, Esq. The bridge for the turnpike road, near Duffield, already known as Moscow-bridge, is nearly completed. Milford tunnel is completed, the last brick remaining only to be laid. The enormous mass of masonry at Belper is rapidly progressing, and the temporary bridge over the wide part of the Derwent, called Belper-pool, is taken up, and the permanent one, nearly 600 feet long, promises to be complete before New Year's Day. The new bed for the river, near Amber-gate, is proceeding with great activity; and the immense bridge of five arches, at the same place, promises completion soon, as we observe centres fixing for the arches, the greater part of two years having been spent, night and day, in getting in the foundations and piers. On the embankments in this neighbourhood, great portions of the permanent way are laid. The difficult undertaking at Bull-bridge, in passing over the turnpike road and under the bed of the canal at the same time, has been easily accomplished, and is all but finished. We observe here water and land piled four stories, one on the other, in a singular manner, thus:—there is first the river Amber, over which goes the turnpike road; over this goes the North Midland Railway; and over the railway flows the Cromford canal. Such a complication of bridges is seldom to be met with. At the station here (Derby) the greatest activity prevails; and there is every indication of an early opening of this line in the spring. A committee of directors, with R. Stephenson, Esq., arrived here by a special train on Monday last, to inspect the works.—*Derby Reporter of Thursday.*

Gloucester and Birmingham Railroad.—The works of this railway, in the neighbourhood of Cheltenham, continue to progress most satisfactorily. The extensive range of buildings near the offices and lodge, already erected, which are designed for the engine-houses, workshops, &c., of the depôt, are in a very forward state, and, unless retarded by the weather, will be all roofed over in the course of a few days. A powerful locomotive engine is now constantly employed in removing ballast, &c., along the line between Cheltenham and Tewkesbury, which portion is so far ready for use, that it is the intention of the directors to make their first experimental trip along it some day next week. The ultimate prospects of this company seem to be most promising.—*Bristol Mercury.*

Eastern Counties Railway Company.—The bridge built by this company over the brook leading from Brentwood to Warley is now finished, and persons travelling that way will find the hill considerably lessened.—*Chelmsford Chronicle.*

Croydon Railway.—The first six months from the opening of this line terminated on the 4th inst.; during that period 311,319 passengers have travelled on the railway, and the money received is £17 666 11*s.* 3*d.*—*Sun.*

Blackwall Railway.—We understand that the Directors have determined upon fitting up an electro-magnetic telegraph along their line, similar to that which we recently noticed as having been for some time in successful operation on the Great Western Railway. In addition to the facilities which such an arrangement will afford in the working of the railway, (an arrangement peculiarly adapted to this line, as we shall take a future opportunity of showing,) the public will be benefitted in no small degree by its application to other purposes. For instance, a vessel coming up the river can, before reaching Woolwich, easily communicate by signals with the railway terminus at Blackwall, and the information being instantaneously conveyed to the Fenchurch-street station, in the immediate vicinity of the great seat of business, parties who are expecting the arrival of friends will at once be prepared to meet them in town, without the necessity of waiting for hours about docks and wharfs; or, if so inclined, can join them at Blackwall, almost as soon as the vessel has reached that point. In the case of steam-boats especially, this will be of great advantage as there can be no doubt that the whole of the passengers by these vessels will at once avail themselves of the railway to avoid the always tedious, and sometimes dangerous, navigation of the Pool. We are glad to find that the works of this short but most important line are proceeding with much vigour, and that the prospects of the Company are in the highest degree satisfactory.—*Railway Times.*

London and Brighton Railway.—Since the opening of the tunnel on the Shoreham branch of the railway, the cutting on New England Farm has made rapid progress; and judging from the appearance of the works, we should suppose that two or three weeks would be sufficient to complete it. The remainder of the line, at the Shoreham end, will, we imagine, take even less time, as only a very few yards of embankment remain to be made, and the permanent rails are already laid on the level of the meadows immediately contiguous to Shoreham. A great number of spectators assemble at New England daily, to witness the ingress and egress of the engine to and from the tunnel. The viaduct over the New England Road, for the London line, is nearly completed; and the progress of the works there, is, we learn, equally rapid and satisfactory with that of the works on the Shoreham Branch, nearer home.—*Brighton Gazette.*

Great Western Railway.—The progress of this immense national undertaking is beginning now to be a work of admiration. Betwixt London and Bristol there are many points of observance showing the wonderful daring results of science which our forefathers never could have anticipated. The wonders of Egypt dwindle into nothing in the comparison. There are gigantic labours without use, the monuments of pride and folly; here use, ornament, and durability seem to try to surpass each other, and their several excellences are so adjusted as to show the foundation of future national prosperity beyond all power of calculation—not only the prosperity of trade by the rapid conveyance of merchandise, but intellectual prosperity, national progress as to mind, by bringing all parts of the empire into more frequent intercourse with large towns, and especially with the metropolis. The most costly portion of the line will be the tunnel at Box. This will ever be in itself a magnificent proof of the skill and enterprise of the age; but these can never be truly estimated, without a knowledge of the overwhelming difficulties encountered in its progress. Of these no evidences will be presented by the work itself, they will be matters only of history. The company deserve high approbation if not national gratitude for their liberal endeavour to make every point of observance an additional beauty to its locality. Even in Bath, the most beautiful city in England, where every thing seems to harmonise in splendour, even here we find the line of works adjacent adding to the general magnificence. The centerings of the arch over the Wells-road, at the bottom of Holloway, have been removed, and erected at the place where the railway will cross Claverton-street. The arch and the two gothic towers are pronounced to be excellent specimens of workmanship; and the entire viaduct, from the taste evinced in its design, will form, when completed, quite an ornament to the neighbourhood. The coffer dam in the Avon, in which the middle support of the proposed bridge will be erected, has not yet been cleared of water, but every effort is being made to effect that object. At the tunnel near Bathwick-terrace the workmen have commenced the formation of a permanent way; and near Hampton-row great advance has been made during the last five or six weeks. At Hampton and the fields beyond, the cuttings and embankments are in a forward state. Close by the stone bridge, between Hampton and Bathwick, the works are also beginning to alter the face of the landscape.—*Bath Journal.*

South Eastern Railway.—The rapid progress of the works is giving quite a lively aspect to Folkestone. The bridge across the Canterbury and Dover road is also completed; and the advancement of the line on either side is going on in a highly satisfactory manner.—*Dover Chronicle.*

Leeds and Manchester Railway.—Rapid progress is making in the construction of the tunnel at the summit between Littleborough and Sodmordon, and it is generally expected that the whole line will be completed in the autumn of the year 1840. The number of passengers now travelling in the railway carriages between Manchester and Littleborough is perfectly amazing and approaches nearly to 3,000 a day; nor is this to be wondered at, when it is considered that it is actually cheaper for a labouring man to ride upon the railroad than to walk upon the highway, as the journey of thirteen miles is performed in half an hour by steam, which would require four hours for a foot passenger, and the fare for travelling in the stand-up-carriages amounts only to one penny a mile.—*Derby Reporter.*

NEW CHURCHES, &c.

Warwickshire.—A new Church is about to be erected at Attleborough, in the parish of Nuneaton, on a site the gift of the Earl of Harrowby. There are upwards of three acres and a half of land, which it is his lordship's wish should be laid out advantageously for the benefit of the clergyman, and it is in contemplation, reserving sufficient for the church, burial ground, parsonage house, croft and schools to form a street of comfortable dwelling houses, the proceeds of which are to form part of the endowment. It is designed by Mr. Thomas L. Walker, in the early pointed style, with a handsome triple west window, and a small tower at the south west angle, containing a clock-room, belfry, ringer's floor, and a staircase leading to a west gallery. At the east end is a semicircular apsis, on each side of which, against the east wall of the church, the pulpit and reading-desk are placed. It is cruciform in plan, a robing-room and a porch forming the arms of the cross. The dimensions of the body, inside the walls, are 73 feet by 39 feet, and is calculated to accommodate 472 persons, viz. 112 in pews, and 360 on benches.

All Saint's Church, Spicer Street Mile End New Town.—On the 25th of November this church, erected and endowed at the expense of the Metropolis Churches Fund, was consecrated by the Bishop of London. It is designed in the Norman style by Mr. Thos. L. Walker, and has a tower, situate on the south side, tabled off and terminated in a neat square bell turret with an octagonal roof. The body of the church measures 74 ft. 6 in. by 54 ft. 6 in. in the clear inside; the roof is in one span, with a queen truss open to the straining piece, it is slightly ornamented, and the timbers are chamfered; the tie-beams are supported by brackets springing from ornamental stone corbels. The pulpit, designed it is presumed to imitate stone, by the details made use of, is rather inappropriately grained heart-of-oak; it is chaste in style, open underneath to admit of an entrance into the reading-desk. The altar piece is cleverly managed, at a small expense, by arched recesses being formed in the brickwork, wherein the Commandments, the Lord's Prayer, and the Belief, are written in appropriate but perfectly legible characters, the initial letters in red and blue, the rest in black on a stone-coloured ground. The chancel is lighted, not from the east as usual, but from the north and south; by this means the glare, which often proves distressing to the congregation, while regarding the preacher, is avoided, while the rays of light, falling upon the altar table from the south, during the greater part of the day, must tend to produce a pleasing effect. Attached to the Church is a spacious vestry, 24 feet by 16 feet, with a neat Norman fire-place executed in Bath stone, and is provided with coal-cellars, &c. There is accommodation for 1110 persons; the church and vestry were contracted for by Mr. West, of Cannon Street Road, at £4095.

New Churches in Wolverhampton.—On Friday, 22 Nov., the plans for a new church in Horsley Fields, one of the intended three new churches in Wolverhampton, were submitted to a meeting of subscribers, in the large room in the Swan Hotel. The plans were 21 in number, and many of them very elegant designs: they were all in the Gothic style. Five of them were selected for further consideration, and were exhibited to the subscribers at large, at the same place.—*Staffordshire Advertiser.*

PUBLIC BUILDINGS, &c.

Warwickshire.—An extensive Hospital, or range of almshouses, is in course of erection at Bedworth, near Coventry, from the designs and under the superintendence of Mr. Thomas L. Walker. The main building forms three sides of a cloistered quadrangle, which sets back 90 feet from the street; towards the street, on the right hand is a porter's lodge, and on the left a tenement to correspond, each with a neat oriel window, leaving the quadrangle open to view, and an iron palisade, with ornamental brick piers and stone caps, complete the street frontage. It is calculated to lodge 40 pensioners, 20 male and 20 female, each having a separate bedroom and pantry; a sitting-room is provided for every two. In the centre of the quadrangle is a spacious dining-room for the governors of the charity, a committee-room, a steward's office, and a kitchen, with accommodation for a nurse. The dining-room is in the form of the ancient halls, and has four bays attached to it; the porch occupies one, the butler's pantry another, and the two others are open to the room: an ornamental screen at the lower end parts off the passage leading from the porch to the committee-room, &c.; over the two front bays are strong-rooms for deeds, one opening into the steward's office, the other is ascended by a circular stone staircase from the hall itself. From the roof of the hall rises an ornamental bell turret, and clock-room in the form of an ancient Louvre. The whole is designed in the late Gothic style, the windows being square-headed, with mullions and transoms, except those of the hall, which are four-centre-pointed, with mullions and tracery. The whole is to be faced with red bricks, and to have stone dressings to the doors and windows and stone motings. Mr. John Toone, of Leamington, is the contractor for all the works, except the hall roof and clock turret, at £8,500.

Llankovery, Carmarthenshire.—The committee appointed to examine and report upon the designs for a market, met in accordance to an advertisement offering a premium for the best design, have adopted the design of G. Clinton, architect of Cardiff.

MISCELLANEA.

EFFECTS OF LARGE FIRES IN PREVENTING STORMS.

(Translated from the French.)

M. Matteucci had pointed out the practice recently introduced into a parish of Romagna of lighting large fires for the purpose of preventing the formation of storms, and remarked that during three years that this practice had been adopted, the parish, which until then had every summer been ravaged with hail, had been spared, while the neighbouring parishes had not escaped.

M. Arago, when quoting this fact in his notice upon thunder, (*Annuaire du Bureau des Longitudes*, 1839), remarked that such short experience would not allow us to consider the result conclusive, and added that more exact data would doubtless be obtained on this subject, by comparing with those of the neighbouring agricultural districts, the meterological observations of certain districts in which high chimneys and large factory fires are used are very numerous. This comparison, said he, had been already made in England, but the results although in favour of the preservative influence of large fires, did not show this influence free from doubt. In fact high furnaces in England are particularly numerous, where there are many mines; the rarity of storms therefore in these places may just as well be attributed to the nature of the soil as to the action of the large fires, which are required for the reduction of the minerals.

M. Matteucci has now pointed out another locality in which this influence of metallic veins is not mixed up with that of large fires. While travelling in the Apennines, he found that those districts in which charcoal and sulphur are prepared, are not much subject to storms, and are free from hail. He was told that about five years ago a hail storm burst over the parish where the sulphur furnaces are, but the place where they are established was preserved. The place mentioned here is Perticaja, near Rimino, where there is a number of these furnaces.

Mr. Cockerill's Manufactory.—Advices from Liege state that Mr. John Cockerill has set out for St. Petersburgh, taking with him one of the chief persons employed at his works, and three engineers. The Emperor Nicholas, it is added, has advanced Mr. Cockerill 10,000,000f. at 5 per cent. secured on all his establishments in Belgium, Russia engaging to purchase annually, to a certain amount, machinery to be manufactured in them, which is to diminish annually, as the Emperor, assisted by Mr. Cockerill, shall have created similar establishments in his own dominions.—*Midland Counties Herald.*

Rouen.—A design for a tomb to receive the heart and statue of Richard Cœur de Lion, in the style of the 12th century, has been prepared by M. Deville, conservator of monuments in the Cathedral of Rouen. It is proposed to place it in the Chapel of the Virgin in the cathedral, near the tomb of Cardinal d'Amboise; and it is supposed that the execution of it will begin before the end of the present year.—*French paper.*

Encroachment of the Sea.—The sea, it is said, is encroaching upon every part of the Cornish coast. In the memory of many persons still living, or but lately dead, the cricketers were unable to throw a ball across the Western Green between Penzance and Newly, which is now not many feet in breadth, and the grandfather of the late vicar of Madron is known to have received tithes from the land under the cliff of Penzance. At a very remote period, we are assured by tradition, that a considerable part of the present bay especially that comprehended within a line drawn from near Cuddon Point, on the east side, to Mousehole on the west, was land covered with wood, but which, by an awful convulsion and irruption of the sea, was suddenly swept away. There is a letter extant, written in the reign of Charles II., to the then proprietor of an estate, which included part of the Western Green, and that part is there estimated at 36 acres of pasturage.—*Penzance Gazette.*

Egypt.—Machines have been brought from England to drain the marshes at Alexandretta, where the stagnant waters fill the country with malaria. The same cause propagates fever in the Egyptian army at Marasch, Adana, and other places. The hospital service is very badly arranged.

Royal Belgian Steamers.—The Belgian Government, in the budget of the Minister of Public Works, alluding to the marine, notifies that "a separate project will be submitted to the Chambers to meet this expense, whether by means of a transfer, or by means of a special credit, destined to complete the system of the railroad by some steam-boats." This measure of M. Nothomb, which is considered, even by the leaders of the Opposition, to be the ablest one projected since the settlement of the country, is the favourite of M. de Theux, and said to be impressively sanctioned in the highest quarter.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 2ND DECEMBER TO 24TH DECEMBER, 1839.

George Davey, of Llandudno, County of Carnarvon, Mining Agent, for "*an improved mode of applying water-power.*"—Sealed December 2; six months for enrolment.

Luke Hebert, of Birmingham, Patent Agent, for "*improvements in the mechanism and process of packing and pressing various articles of commerce.*" Communicated by a foreigner residing abroad.—December 2; six months.

Miles Berry, of Chancery Lane, Patent Agent, for "*certain improvements in machinery or apparatus for making or manufacturing pins and sticking them in paper.*" Communicated by a foreigner residing abroad.—December 2; six months.

Godfrey Anthony Ermen, of Manchester, Cotton Spinner, for "*certain improvements in machinery or apparatus for spinning, doubling, or twisting cotton, flax, wool, silk, or other fibrous materials, part of which improvements are applicable to machinery in general.*"—December 2; six months.

John Evans, of Birmingham, Paper Maker, for "*improvements for chemically preparing and cleansing of felts used by paper manufacturers.*"—December 2; six months.

Henry Dunington, of Nottingham, Lace Manufacturer, for "*improvements in machinery employed in making frame work knit, or stocking fabrics.*"—December 2; six months.

James Guest, Junior, of Birmingham, Merchant, for "*improvements in locks and other fastenings.*"—December 2; six months.

George Saunders, of Hooknorton, Clerk, Oxford, and James Wilmot Newbery, of the same place, Farmer, for "*improvements in machinery for dibbling or setting wheat and other grain or seed.*"—December 2; six months.

Henry Trewhitt, of Newcastle-on-Tyne, Esq., for "*certain improvements in the fabrication of china and earthenware, and in the apparatus or machinery applicable thereto.*" Communicated by a foreigner residing abroad. December 4; six months.

Christopher Nickels, of York Road, Lambeth, Gentlemen, for "*improvements in propelling carriages.*" Communicated by a foreigner residing abroad.—December 4; six months.

Pierre Narcisse Cronier, of Fricourt's Hotel, Saint Martin's Lane, for "*improvements in filters, and in the means of cleansing the same, and for separating, colouring, and tanning matters for filteration, and for improvements in employing such tanning matters by filtration.*" Partly communicated by a foreigner residing abroad.—December 4; six months.

James Mayer, of Ashley Crescent, Saint Luke, Gentlemen, for "*an improved machine for cutting splints for matches.*"—December 4; six months.

George Lowe, Engineer to the Chartered Gas Company, and John Kirkham, Engineer to the Imperial Gas Company, both of London, for "*improvements in the manufacture of gas for purposes of illumination.*"—December 4; six months.

James Nasmyth, of Patricroft, near Manchester, Engineer, for "*certain improvements applicable to railway carriages.*"—December 4; six months.

John Heaton Hall, of Doncaster, Chemist, for "*improvements in preserving and rendering woollen, and other fabrics, and leather waterproof.*"—December 5; six months.

Harrold Potter, of Manchester, Esquire, for "*certain improvements in printing calicoes, muslins, and other fabrics.*"—December 9; six months.

Samuel White, of Charlton, Marshatts, Dorset, Esquire, for "*improvements in preventing persons from being drowned.*"—December 9; six months.

Moses Poole, of Lincoln's Inn, Gentleman, for "*improvements in the manufacture of caustic, soda, and carbonate of soda.*" Communicated by a foreigner residing abroad.—December 9; six months.

Thomas Richardson, of Newcastle, Chemist, for "*a preparation of sulphate of lead, applicable to some of the purposes for which carbonate of lead is now applied.*"—December 9; six months.

John Leslie, of Conduit Street, Hanover Square, Tailor, for "*improvements in measuring the human figure.*" Communicated by a foreigner residing abroad.—December 9; six months.

John Juckes, of Shropshire, Gentleman, for "*improvements in furnaces or fire-places for the better consuming of fuel.*"—December 9; six months.

Pierre Frederick Gongy, of Tavistock Street, Westminster, Watch Maker, for "*an improvement in clocks, watches, and other time-keepers.*"—December 11; six months.

Robert Hervey, of Manchester, Drysalter, for "*certain improvements in the mode of preparing and purifying alum, alumina, aluminous mordants, and other aluminous combinations and solutions, and the application of such improvements to the purposes of manufacture.*"—December 13; six months.

Robert Gill Ransom, of Ipswich, Paper Maker, and Samuel Millbourn, foreman to the said R. G. Ransom, for "*improvements in the manufacture of paper.*"—December 13; six months.

Angier March Perkins, of Great Coram Street, Civil Engineer, for "*improvements in apparatus for transmitting heat by circulating water.*"—December 13; six months.

Jacob Brazill, Governor of Trinity Ground, Deptford, for "*improvements in obtaining motive power.*"—December 16; six months.

Henry Seymour Moore Vandeleur, of Kilrush, Ireland, for "*improvements in paving or covering roads, and other ways.*"—December 16; six months.

Samuel Walton Faxton, of Park Village East, Regent's Park, Surgeon for "*an apparatus to be applied to the chimneys of gas and other burners, or lamps to improve combustion.*"—December 16; six months.

Monnin Japy, and Constant Jouffroy Dumery, of George Yard, Lombard Street, Gentlemen, for "*improvements in rotatory engines, to be actuated by steam or water.*"—December 16; six months.

David Morison, of Wilson Street, Finsbury, Ink Maker, for "*improvements in printing.*"—December 16; six months.

David Naylor, of Copley Mill, Halifax, Manufacturer, and John Crighton, Junior, of Manchester, Machine Maker, for "*certain improvements in machinery for weaving single, double, and treble cloths, by hand or power.*"—December 16; six months.

George Wilson, of Salford, Machinist and Engineer, for "*certain improvements in steam-whistles adapted for locomotive engines and boilers, and other purposes.*"—December 16; six months.

John Robinson, of North Shields, Engineer, for "*an improved steering apparatus.*"—December 16; six months.

John Wood, of Burslem, Stafford, Manufacturer of Mineral Colours, for "*a new method or process in the application and laying on of the substances used in the printing, colouring, tinting, and ornamenting of china, porcelain, earthenware, and other wares of the same description, by which such wares can be printed and ornamented with flowers and other devices in a much cheaper and more simple and expeditious manner than by any process now in use, and colours of all or any variety may be printed, shaded, mixed, and blended together in one of and the same design or pattern, and hardened or burnt into the substance of the aforesaid wares by a single process of firing or hardening in the enameling kiln.*"—December 16; two months.

James William Thompson, of Turnstile Alley, Long Acre, Upholsterer, for "*improvements in the construction of bedsteads, which improvements are particularly applicable to the use of invalids.*"—December 16; six months.

William Newman, of Birmingham, Brass Founder, for "*certain improved mechanism for roller blinds, which it is intended to denominate Simcox and Company's patent blind furniture.*"—December 16; six months.

Joseph Gibbs, of Kennington, Surrey, Engineer, for "*an improvement or improvements in the machinery for preparing fibrous substances for spinning and in the mode of spinning certain fibrous substances.*"—December 21; six months.

George Lindsay Young, of Hackney, in the county of Middlesex, Gentleman, for "*an improved surface for paper, mill or card board, vellum and parchment.*"—December 21; six months.

Henry Francis Richardson, of Ironmonger Lane, Gentleman, for "*improvements in omnibuses.*"—December 21; six months.

John Cutts, of Manchester, Machine Maker, and Thomas Spencer, of the same place, Mechanic, for "*certain improvements in the machinery or apparatus for making wire cards for carding cotton, silk, wool, and other fibrous substances.*"—December 21; six months.

Laurence Wood Fletcher, of Chorlton-upon-Medlock, Manchester, Machinist, for "*an improvement or improvements in the manufacture of woollen and other cloths, fabrics, and in the application of such cloths or fabrics to various useful purposes.*"—December 23; six months.

Thomas Firmstone, of Newcastle, Coal Master, for "*improvements in the manufacture of salt.*"—December 24; six months.

Alexander Mac'Rae, of the London Coffee House, Ludgate Hill, London, for "*improvements in machinery for ploughing, harrowing and other agricultural purposes, to be worked by steam or other power.*"—December 24; six months.

Thomas Hardeman Clarke, of Birmingham, Cabinet Maker, for "*certain improved fastenings for window sashes, tables, and such like purposes.*"—December 24; six months.

TO CORRESPONDENTS.

R. H.—*The Marquis of Tweeddale's brick and tile-making machine is patented, and licences are granted for using it in various parts of the kingdom.*

The communication of M. N. O. *will appear next month.*

A Catholic must excuse us for not publishing his last communication.

The Epycycloidal Motion for a Steam Engine is not new.

A lithographic drawing of a Church was received from Norwich by our publisher, but unfortunately it has been mislaid, we were charged 2s. 8d. *for carriage and porterage for it, we trust that our correspondent will not in future put us to that expence.*

We have been obliged to postpone some important Engravings, which we could not get ready in time, until next month.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No.* 11, *Parliament Street, Westminster, or to Mr. Groombridge, Panyer Alley, Paternoster Row; if by post, to be directed to the former place; if by parcel, to be directed to the nearest of the two places where the coach arrives at in London, as we are frequently put to the expence of one or two shillings for the* porterage only, *of a very small parcel.*

Books for review must be sent early in the month, communications on or before the 20th (if with wood-cuts, earlier), and advertisements on or before the 25th instant.

The First Volume may be had, bound in cloth and lettered in gold Price 17*s*.

*** The Second Volume may also be had, Price 20*s*.

HARVEY AND WEST'S PATENT IMPROVED VALVE *for Machines for Raising Water and other Liquids.*

SPECIFICATION.

Now know ye, that our improved valve resembles, in appearance, a valve known by the name of the "double beat valve," used in certain steam engines; our improvement consists in making the same self-acting, so that it can work without the aid of machinery for opening and shutting it, and thereby is applicable to machines for raising water and other liquids.

In our improved valves the area of the upper part of the seat, on which the top of the valve beats, is made less than the area of the lower part of the seat, on which the bottom of the valve beats, the valve being made of course to correspond, and the difference in area between the two must be such that, when the valve is used in the place of the lower valve in a pump through which the water passes into the pump barrel, the pressure of the atmosphere upon the under side of the valve (brought into action by creating a partial vacuum upon the upper side of the valve when motion is given to the piston, bucket, or plunger-pole of the pump,) shall be sufficient to overcome the weight of the valve, and cause it to rise, and when the valve is used in place of the upper valve, through which the water is forced out of the pump barrel, or when used in lieu of the valves upon the pump bucket, the difference in area must be such that the pressure upon the under side of the valve, (caused by the motion of the piston, bucket, or plunger-pole forcing the liquid through it,) shall be sufficient to overcome the weight of the valve, and cause it to rise; the opening in the top will be less than the opening in the bottom of the valve, and the surface of the ring upon the top of the valve, which will be equal to the difference between the area of the two openings, must be made proportionate to the weight of the valve itself, the action will be more fully understood by reference to the drawings and explanation thereof hereinafter given.

The advantages to be obtained by the use of our improved valve, are 1st, That as the area of the valve exposed to the pressure of the column of water, or action of the piston upon its return stroke, is considerably less than in the ordinary circular, hanging or butterfly valves, the blow and consequent vibration caused by the shutting of the valves, is considerably diminished, and less costly foundations are therefore required. 2d. The loss of water upon the shutting down of the valve is considerably diminished. Our improved valves may be used for the upper and lower valves of all varieties of pumps.

In order to explain more clearly the construction and action of our improved valve, we will now refer to and describe the drawings, representing plans, elevations, and sections of it. The same letters of reference are marked upon all the figures.

Figure 1 is an elevation of the valve and its seat, the valve being shut. Figure 2, a top view thereof, the valve being open or shut. Figure 3, a vertical section through the valve and seat, the valve being shut. Figure 4, a vertical section through the valve and seat, the valve being open. Figure 5, an elevation. Figure 6, a plan. Figure 7, a vertical section of the valve detached from its seat. Figure 8, an elevation. Figure 9, a plan. Figure 10, a vertical section of the seat. Figure 11, a horizontal section of the ribs through the line *a b*, in fig. 10, and plan of the bottom or lower beat; *c c c c* the seat made of cast iron or other metal, upon which the valve *d d* works. The valve may be made of cast or wrought iron, gun-metal, brass, copper, or other metal, according to the size, the quality of the water, or other circumstances. The rings *e' e' e e* are faced, that is are turned true, and when shut, fit accurately to the beats *f' f'* and *f f* upon the seat *c' c c c*; *f f* is the lower beat, and *f' f'* is the upper beat. In fig. 7 *e' e'* is the top opening of the valve, and *e e* the bottom; the beats may either be formed by a raised ridge cast, or wrought upon the seat, and faced or turned true, or by introducing into circular grooves, cast in the seat, a ring of wooden wedges, or of soft metal; the top surface in either case to be faced or turned true, to receive the valve—we prefer wood or soft metal; *g g* represents a circular groove cast or wrought, on the under side of the seat, into which leather is introduced, so as to prevent leakage when the seat is bolted down in its place. *h h* is a cylinder cast upon the seat and turned true, so as to form a guide for the valve to work upon, and to keep it in its right place. *i i* is a metallic feather attached to the cylinder, and projecting into a groove formed in the valve, to prevent any circular motion in the valve; and *k k* is a cap bolted upon the cylinder to prevent the valve rising beyond a given height, or being displaced. The dotted lines *l l l*, *l l l*, fig. 4, represent the direction that the water takes when the valve is opened. *m m* represent the surface of the valve that is exposed to the pressure of the atmosphere, or force created by the motion of the piston, and which when proportioned as hereinbefore described, by making the difference in area between the space by the rings circumscribing the top and bottom openings of the valve, sufficiently great to allow the force applied to overcome the weight of the valve, will cause it to rise.

Having now described our improved valve, and in doing so, having also described certain contrivance and constructions, which we do not claim as our improvement, but the description of which was necessary to elucidate our improvement: we hereby declare that we claim as our improvement that part of the contrivance only which makes the valve self-acting, by making the area of the top opening of the valve less than the bottom, and making the seat to correspond thereto, which area must be varied according to the size and weight of the valve, and must be proportioned thereto.

IRON TIES THROUGH PARTY WALLS.

Experiments tried at Chatham on the 6th of December 1839, in respect to iron ties passing through party walls to form a continued bond for the floors of adjacent houses.

In the course of practical architecture taught to the junior officers of the Royal Engineers of Chatham, the floors of two adjoining houses are connected by ties, each consisting of a strap of iron passing through a party wall, and bolted to the sides of two girders, in the same allinement, which sort of tie-bond may be supposed to be continued through the whole extent of a range of barracks, or of a row of houses, as was done by Messrs. Baker in their new houses on the north side of the Strand, near Exeter Hall.

The utility of this sort of continued bond could scarcely be doubted, but a query having often suggested itself, whether the destruction of the floors of one house by fire, might not heat the iron-ties passing through the party walls, on each side, so far as to endanger the floors of the two adjacent houses; Colonel Pasley directed Captain Williams to try the following experiment, which must be considered conclusive.

In the accompanying figures, *w* is a 9 inch brick wall, 6 courses high, representing a portion of a party wall between two adjoining houses. For the convenience of applying the fire, it was built upon the hearth of a smith's forge. The 4 inch wall *c*, *c*, were added merely to enclose the fuel, and to increase its heat. These walls were built the day previous to that on which the experiment was made; and as common lime mortar would have required considerable time to dry, cement

Fig. 1, Plan.

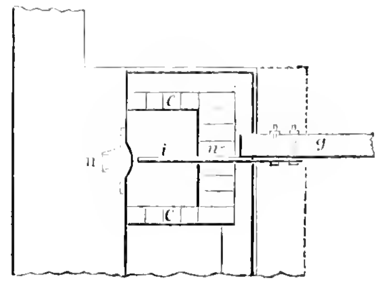

Fig. 2. Section.

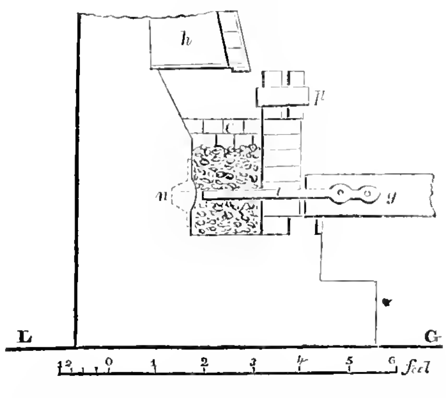


p six pigs of iron ballast, each 56 lbs. to prevent the brickwork separating by the heat. *h* Hood. G, L, Ground Line.

mixed with sand was used instead of lime; *g* is a piece of Memel timber, 3 feet long, 6 inches wide, and 11 inches deep, representing part of a girder, having an interval of one inch between the end of it and the party wall: *i* is the iron strap, 3½ feet long, 2½ inches wide, and ½ inch thick, bolted to the girder *g*, and passing through, and extending beyond the wall to within one inch of the nozzle *n*, of the tew iron of the bellows. One foot four inches of its length was exposed to the fire, which was lighted at ten o'clock A.M.

By eleven o'clock the fire was in good action throughout: the coals were well heaped over and about the iron strap to within 5 or 6 inches of the top of the wall, and the heat was kept up to the greatest practicable intensity, by the uninterrupted action of the bellows, till four o'clock P.M.

It was one o'clock before that part of the iron strap in contact with the girder became too warm, even close to the wall, to render it necessary to withdraw the hand from it, and even at four o'clock, by which time 5 inches of the end nearest the tew iron were burnt completely away, there was not sufficient heat in any part of it outside the party wall, either to discolour dry wood shavings or paper, or to ignite naptha. At 6 inches from the wall the hand could be continued on the iron without inconvenience during the whole period the experiment occupied, and at no time was the party wall red hot.

There can be no doubt but that the fire might have been kept up long enough to consume the whole of the iron surrounded by it, without sufficient heat being communicated to the girder to set fire to it.

The bulb of a thermometer that happened to be at hand, was applied to the iron, where it entered the party wall, but the degree of heat could not be determined, as the tube extending only to 118 degrees of Fahrenheit, was very soon filled by the quicksilver, and was then withdrawn to prevent it from bursting.

The cement mortar in the joints of the brickwork nearest to the fire was reduced to dust. In this state, Colonel Pasley ordered some balls of it to be mixed up with water, into the consistency of a stiffish paste, which set rather slowly, but in the course of a few days became extremely hard, in consequence of the cement having been calcined by the fire, and thereby restored to the same state, in which it had been received from the manufacturer.

BALANCE GATES.

Erected at the Works of the East London Water Works Company, Old Ford. Engineer, Thomas Wicksteed, Esq., M. Inst. C.E. *With two Engravings, Plates* II. & III.

In the year 1833, the East London Water Works Company made very considerable alterations and additions to their works, by cutting a canal for the purpose of bringing the water from a higher part of the river Lea, near the Lea Bridge Mills, to their works at Old Ford, and to guard against any deficiency of water for the working the mills on the river Lea, and to satisfy the owners of the mills, the Company agreed, in the Act of Parliament authorizing them to make the alterations, to form a large compensating reservoir covering about 14 to 15 acres of land, with two entrances, one at the south-east corner of the reservoir, near to Old Ford Lock, where there is erected a pair of tide or flood-gates, for the *admission* of water only as the tide rises, and another entrance at the eastern corner of the said reservoir upon the banks of the river Lea, above the City Mill Point, consisting of three openings with six balance gates, for the *admission* of water from the river, and for *discharging* the water out of the reservoir into the river for the use of the millers. As the tide flows up the river it fills the reservoir, and when the tide ebbs, if required by the millers, the water is allowed to run out into the river, and thus compensate them for any quantity of water that might be abstracted from the upper part of the river for the purposes of the company.

It is our present object to confine ourselves to the description of the Balance Gates, which are well deserving of notice by the profession, and to point out where they differ from the Dutch system of construction.

As the neap tides at the point of delivery rise only, on some occasions, a few inches, and as consequently a very large quantity of water might have to be delivered in a very short space of time, with so low a head or pressure, a great width of outlet became requisite; if the ordinary sluice gates had been erected, the time required to open them would have been above an hour and a half, and consequently the whole of the water might not have been returned into the river before the preceding low water; whereas the balance gates, as we can bear witness to, are easily opened or closed in ten minutes, *against* a pressure of water.

The essential difference between the gates designed by Mr. Wicksteed, and the old Dutch balance gates as described in Belidor's Architecture Hydraulique, is this—the old gate is larger in area on one side of the centre than the other, on the largest side a sluice gate is introduced, which when opened reduces the area of the largest side, so that it becomes less than the other, which was before the sluice was opened, largest; by this arrangement when the sluice gate is shut the pressure of the water upon the largest area causes the gate to remain closed, but when the sluice is opened the greatest pressure is upon the other side (or *half*) of the gate, and causes it to open *but not completely*, and tackle must be made to open it *wide*. In Mr. Wicksteed's gates the sides are of equal area, and they are made to open at once by a toothed quadrant and pinion: two gates are also introduced in each opening, and set at an angle which gives strength to their construction and saves masonry. When the gates are closed, by the application of a very ingenious contrivance, consisting of a vertical iron shaft fixed in the hollow quoins, with three eccentrics or cams upon it, they are made to close against each other, and against the cills and recesses in the side walls, so that no leakage whatever takes place.

These gates are, we believe, the only ones of the kind erected in the kingdom, and when we were favoured with a view of them, they had been in use for six years and in excellent working order, they had not been repaired since they were first erected by Messrs. Hunter and English, of Bow, whose reputation as millwrights is so well known, that they needed not this accession to their fame.

The cost of the gates we could not ascertain, as they were done in conjunction with other works by contract, but we can easily give credit to Mr. Wicksteed's statement that the expence was not more, if so much, as common sluice gates with their elevating machinery, foundation, &c., when it is considered how many sluices there must have been to insure the same width of opening.

These gates are different in construction, and are used for a different purpose to those erected some years since at Lowestoff; with the exception of these two instances, we are not aware of any other gates erected upon the Dutch principle in England, but we think there are many cases in engineering where their introduction might be advantageous.

The following additional particulars we select from the contract and specification of the work, which will together with the engravings give an accurate view of their construction.

"They (the Balance Gates) are different in construction to the common flood-gates; a description of one gate will answer for the whole: the gate is made to work upon a vertical shaft as a centre, and is equal on each side thereof. One gate, when closed, shuts against another gate on one side, while the opposite sides close against a recess in the piers or side walls. It will appear evident, upon an inspection of the plans, that the gates being equal on each side of the vertical shaft, which is the centre of motion, whatever pressure of water may be against them, that there is as great a tendency to keep the gate closed as there is to open it, and that being, under any circumstances, equally balanced, a very slight exertion of power (sufficient to overcome the friction of the working parts) will either open or close them. When the gates are closed, and it is desirable to retain the water in the reservoir, to destroy the effect that any vibration might have upon them to cause a leakage, a shaft is introduced upon which three eccentrics are cast, which, when applied to the gates, pinches them against their abutments, and thus prevents any leakage that might by possibility occur. When it is desired to open the gates to discharge the water of the reservoir into the river, the eccentric is first to be worked so as to take off its effect upon the gate, and then the quadrant and pinion must be worked to open the gate, which, as the pressure of water is equal in its action upon both sides of the centre, will be a matter requiring but a small exertion of power.

Description of the Work.—The framing of the balance gates is to be of good English oak timber; the planking to be the best Memel plank. All the joints are to be made sound and good; the mortices to be cut out square their whole depth, and the tenons to be made so that they shall fit equally over every surface; the butting joints to be squared so as to touch and bear equally over the butting surface. Wherever the timbers are framed into the iron-work, the iron-work shall be made true and good to receive it, so that it shall bear equally on all the surfaces; and wherever wrought iron straps are let into the timbers, they shall be fitted accurately; no packing will be permitted, but the iron must fit fairly and strictly to the wood. All keys and bolts for straps, and cast iron work must be made to fit accurately, so that the bolts fill up the holes made for their reception, without shaking or depending, upon the friction of the head and nut.

The timbers are to be rebated for the reception of the ends of the 2-inch fir planking, so that when the planking is introduced, the surfaces of the planking and timbers shall be flush—the planks are to be 2 inches thick and 9 inches wide, to be laid diagonally, as described in the drawings; at the two ends, and wherever there is a cross or diagonal timber, the plank shall be fastened thereunto by means of 2 screw bolts at every bearing, and wherever iron intervenes between the planking and timber, it shall be drilled, and the bolt shall fit accurately, iron to iron—the screw bolts are to be 5-8ths of an inch diameter, and 5 inches long, with square heads, and a neat iron collar under each head and nut, excepting where iron intervenes, when the bolt shall be as much longer as the thickness of the iron, so that every bolt shall have a screw of 3 inches deep in the timber. The joints of the planking shall be shot straight, fitted close, and caulked, so as to render every joint perfectly water-tight.

The pivots on which the gates revolve are to be cast hard, and fitted accurately to the hollow bearing in the vertical shaft.

The gates are to be made accurately at the meeting posts. At the sides which abut against the piers and walls, and at the cills and wherever iron intervenes, it shall be chipped and filed so as to fit flush with the timber, so that no water shall escape at the joints—the pivot and step are to be so made that the least possible leakage shall take place.

All the cast iron bearings are to be accurately turned, so as to work truly and easily, and in every case where iron works in iron, *either* the shaft *or* bearing is to be cast hard, as may be deemed advisable by the Company's engineer—the upper bearings to have set screws and keys for adjustment, as described in the drawings. All the wheel work is to be fitted accurately, and if required by the Company's engineer, the teeth are to be chipped and filed.

The same directions that are given hereinbefore for the joints in the timber and connecting straps and bolts, are to be observed in the construction of the trussed foot-bridge, which is to be wholly of the best Memel fir.

Reference to Engravings.—Plate II.

Fig. 1.—Plan of the Balance Gates, Sills, Inverts, and Piers. In "Invert No. 1," the sill pieces are shown, and the iron pivots upon which the gates are to turn. In "Invert No. 2," the gates are shown at an horizontal section through the timbers and planking, and vertical shaft; the eccentric shafts are also shown. In "Invert No. 3," the top view of the gates is exhibited with the quadrant and pinion for working the gates, and the wheel upon the top of the eccentric shaft.

Fig. 2 is an elevation of the work described in Fig. 1. The gates, however, are shewn in *projection*, or as they will appear when closed; the trussed foot-bridge for the support of the upper bearings of the shafts upon which the gates turn, is also shown in elevation and section.

Fig. 3.—A transverse section through C D (Fig. 1) of the gate and trussed foot-bridge, and an elevation of one of the piers and section of the invert, sill, and apron.

Fig. 4.—Transverse section through A B (Fig. 1).

Fig. 5 is a plan of the trussed foot-bridge, a portion of it planked as it will appear when finished, and another portion as it will appear before the planking is laid down, exhibiting the trussing and cast iron frames for the support of the upper bearing of the vertical shafts.

Plate III—contains enlarged views of the gates described in Plate II, which may be sufficiently understood by reference to the drawings.

LONDON SHOPS.

[A very able and interesting article on "London Shops and Gin Palaces," by Candidus, appeared in the December Number of *Fraser's Magazine*, from which we select the following extracts.]

We need not speak of the very superior mode in which shop-windows are now fitted up, not merely as regards the large squares of glass, and the more than atlas folio sheets of plate-glass, which have of late become almost so common as to cease to excite astonishment, but also in respect to the framework of the windows, the polished brass-work which covers the window-sill. One contrivance, however, which has been but very lately introduced, will, when it comes to be more generally adopted, greatly enhance the appearance of the shops after dark,—we mean that of throwing a very powerful light upon the goods at the window, the first experiment of which was made, we believe, on the east side of Temple Bar, viz. at the splendid new shop opened in St. Paul's Churchyard by Hitchcock and Rogers; which, in point of extent, has scarcely a rival in any other part of the town. The proprietors appear to have spared no cost to render their establishment as attractive as possible even to the very labels or tickets attached to the goods, which, instead of being merely written, are tastefully emblazoned on large card-boards, in gold, azure, and other brilliant colours. Still, when we come to consider this, and some other shop fronts of the same class, architecturally, we cannot help being offended at a defect which is here carried *à l'outrance*, to a much greater degree than any where else. In fact, the whole of this unusually extensive shop front presents to the eye nothing but glass set in very slender upright brass styles, or bars, without any apparent support whatever — without even jambs to the doors — so that the house itself, over the shop, has the look of being miraculously suspended in the air, after the fashion of Mahomet's coffin: and this not particularly agreeable appearance is strikingly increased by its returning on the west side, without any indication of prop or stay of any kind beneath the superincumbent angle of the upper part of the structure, which is actually suspended over that corner. There is no doubt that sufficient precaution has been taken to ensure security; and so far we are at liberty to admire the skill shewn by the builder in achieving what is certainly a *monsterpiece*, if not a masterpiece, in construction. His task may have been exceedingly difficult; yet we are tempted to say, with Dr. Johnson, that we wish it had been impossible. It will, perhaps, be argued, that what we here behold is, after all, not a whit more contrary to sound architectural taste than a geometrical staircase, where the steps are attached to the wall only at one end. The two cases, however, are not perfectly similar; because, in the second instance, each step is no more than either a balcony or large bracket inserted into the wall, whereas, in the other, the bressumers of the floor, above the shop, have to support all the upper part of the front, while they themselves seem to rest upon nothing except the slight frame in which the glass of the shop window is fixed. As far, therefore, as the general aspect of such front is concerned, the effect is disagreeable; while, as regards the lower part, or shop itself, taken distinct from the rest, it is exceedingly insipid and poor—very little better than what would be produced by the same space of unglazed opening for the display of goods; the chief difference being, that instead of being exposed to injury, the articles so exhibited are protected by the glass.

No doubt, every tradesman is anxious to make as attractive a display as possible of the articles he deals in; but it is, nevertheless, a great error to suppose that this is best accomplished by making the shop-window as large as the width of frontage will permit, and then to put up at it as much as it will contain. In fact, this mode—the one now almost invariably resorted to, and in many cases carried to an extent quite preposterous—rather defeats the object aimed at, because it utterly excludes all variety of design, or rather excludes design itself—reducing the whole front of each shop to only so many feet superficial of glass. Hence there is nothing to distinguish any one shop from the rest—nothing to mark it out to the eye from any distance. If strikingness of character be at all an object worth attending to, it might be far more easily and more satisfactorily accomplished by adopting a contrary system to that now in vogue, dividing what is now a single window into distinct compartments, the spaces between which would afford room for decoration, together with ample scope for invention. It is true that, as far as mere quantity goes, the display would be less than at present; but then the show of goods might frequently be rendered more striking, and might be every day made a fresh one, by some of the articles being changed. The great desideratum, it may be presumed, is to render the shop itself a conspicuous object—one that cannot fail to arrest the attention of every one who passes; and this, we conceive, would, in most cases, be better accomplished by making it a catching architectural "frontispiece"—no matter how much the space now allotted to a window might be trenched upon for such purpose. * *

Even at present we have one or two things, which, although they do not exactly exemplify the mode of design we could wish to see adopted, may be quoted as instances of very superior taste, and withal, of more originality and study than are to be discovered in buildings of far greater importance. Among these, we do not hesitate to say that the *facile princeps* for *recherché* elegance of design, for purity of taste, for happiness of invention, in the whole composition, together with admirable beauty of finish, is a small shop front, or, rather, a small façade, in Tavistock Place. It is an exquisite architectural gem—at least every professional man and real connoisseur must at once recognize it as such—although its beauties and merits are of that kind which are not likely to ensure it particular attention from persons in general; because in such matters the million are apt to form their estimate according either to size or to gaudy showiness. No man who understands architecture can look at it without feeling that the worthy George Maddox here worked up his ideas *con amore*, with the relish of one enthusiastically devoted to his art for his art's sake. The whole of this front—for we ought to observe that the design is not confined to the lower part or shop alone—is in perfect keeping: we do not find merely a very good bit in this place, a very nice piece of ornament in another; something happy there, and something not amiss here, but the *ensemble* is complete; the same taste pervades every part: nothing can either be added or taken away without detriment to the whole. What simplicity in the general character of this little façade! yet so very far is it from partaking of any thing like poverty, that it is particularly remarkable for the unusual care bestowed upon all its details. Indeed, there are only one or two buildings in the whole metropolis that can stand the test of comparison with it in that respect. Examine the capitals and entablature of the order that forms the shop front itself, and you must allow them to be no less beautiful than novel, that is, supposing you are competent to appreciate the originality and taste there manifested. After all, it must be allowed to have one unpardonable fault: how great soever may be its merits in point of design, it wants magnitude—at least to give it sufficient consequence and importance in the eyes of ordinary beholders. Truly it does; and so, also, does that beautiful little architectural gem of antiquity, the monument of Lysicrates, which, in regard to size, is little better than a mere model, or toy. To be sure, the one example is at London, the other at Athens; and that, it must be acknowledged, does make a vast difference in the opinion of the vulgar, both learned and unlearned. Most certainly, there is no denying that Tavistock Place is not Athens, any more than that Saffron Hill is not Mount Hymettus.

The only thing that can fairly enter the lists with the façade we have been speaking of, is the one No. 22, Old Bond Street, which is likewise singularly beautiful, and treated throughout with true artistical feeling. It is the production of the Messrs. Inwood, or of one of the brothers, and it certainly displays more invention and taste than all their other designs put together, if we except the columns and doors in the portico of St. Pancras Church; the former of which, however, are merely copies from those of the triple temple on the Athenian Acropolis. These two are almost the only instances in which the whole of such a front is consistently designed and decorated throughout, so as to be altogether of a piece from bottom to top; for the shop and the house above it are, we may say, invariably treated as distinct from each other, instead of being combined, as far as their inevitable difference of character will permit, into one uniform composition. This is more or less the case, even where architectural embellishment is liberally bestowed on the upper part of the front, the superstructure having so little architectural connexion with the basement on which it stands, that the effect is quite incongruous. Of this we have notable proof in a shop in St. Paul's Churchyard, already spoken of; since, so far from there being an apparent connexion between one part and another, we might fancy that the upper portion, with its Corinthian pilasters, had been taken off from a rusticated basement, and suspended upon the huge glass case beneath it, which it threatens to crush. A greater architectural antithesis than the one thus produced can hardly be imagined, the whole of the lower portion presenting the very minimum of strength, an appearance of unusual weakness and fragility, while the upper has a more than usual character of solidity, owing, among other circumstances, to the breadth of the piers between the windows; that is, however, of solidity when it is considered apart from its baseless position, because that exceedingly false position gives it the appearance of being particularly insecure, and in imminent peril of performing an *aplomb*.

Perhaps, of the two inconsistencies, it is the lesser one where, as is almost the general rule, architectural expression is confined to the shop-front itself, all the rest being left quite unpretending and plain, even to nakedness. It must be admitted, that the other method is greatly preferable, as far as the general appearance of a street is concerned, inasmuch as it conduces to its architectural dignity; yet, as regards the houses individually, it is better that the shop-front itself should be made exclusively the feature on which architectural design is bestowed, unless, indeed, it can be consistently carried on upwards.

Although frequently no other economy than that of space seems to be regarded, it cannot be affirmed that much either of invention or taste is displayed in our London shop-fronts, of which carpenters seem, for the most part, to be the designers; yet here and there one may meet with a clever bit,—good both in regard to ornament and composition. These, however, form merely the exceptions: for the taste usually displayed is most flimsy and frippery, and full of inconsistencies. At the best, things of this kind can be little more than mere bits; because, owing to their want of size, they can hardly produce any effect in a general view, or until approached and examined; yet that is no reason wherefore they should be undeserving of examination, and bits of tawdry trumpery in themselves. On the contrary, if they do not afford much latitude for the display of design and invention in any other respect—an opinion, however, to which we ourselves are strongly opposed—they most incontestably offer ample scope for experimentalising in the way of columns and entablatures. Nevertheless, so far from any advantage being taken of this, we scarcely ever find any novelty whatever of decoration attempted in regard to such features, which are no other than copies from Stuart's plates. However anti-classical, gimcrack, Cockney, every other part of such design may be, we behold Grecian Doric and Grecian Ionic copied with most superstitious exactness, and repeated *usque ad nauseam*. The Athenian Doric of the Parthenon, and the Pæstan example of the same order, are most ridiculously *minified*, and applied when they are most offensively out of place, putting us out of conceit both with them and with what but for them would have been honest, unsophisticated, Cockney carpenters' work. Away with the worse than schoolboy—the dull schoolmaster vapouring, about the intrinsic beauty of form and proportions belonging to the ancient orders, as if they possessed an indefeasible charm adhering to them under any circumstances. At that rate, it would be excellent taste to convert the legs of a table into four pigmy columns, Doric or Ionic; or if the mere models of such things possess in themselves a magic charm for the eye, neither could they fail to please were they dragged in any where else for the nonce, even should it be into a Gothic building. The truth is, no such kind of beauty exists either in them or any thing else: a fine arm and hand are very beautiful in a fine woman, or, for the matter of that, even in a plain one; yet how they could be made to add to the beauty of a horse, we certainly do not see. Of all the styles, the one least suitable for purposes which require it to abandon more or less of its original character, is the Grecian Doric, whose sternness and severity, apart from the imposing grandeur attending magnitude of dimensions, are apt to degenerate into frigidity and hardness when the order is exhibited upon a trivial scale. Instead of attempting to counteract this defect, which predominates in most modern imitations of that style, we increase it by omitting all sculpture and other decoration, as not included in the idea of the architecture itself, although it is essentially indispensable to its effect. By the chilling bareness thus occasioned, a style naturally stern in itself becomes aggravated into disagreeable harshness; more particularly when reduced to more than ordinary insignificance of size; for all dignity of expression is lost, and in lieu of it we obtain poverty of style, with an affected heaviness of form,—something nearly as grotesque as a little Cupid proportioned after the brawny form of the Farnese Hercules.

Yet such is the style upon which, at least, one-half of our modern shop-fronts are modelled. As far as the columns alone go, they are tolerably accurate, and intolerably dull fac-similes of the different examples measured by Stuart and others; but there all resemblance ends. The frieze—should there happen to be any such member in the entablature—is as plain as the architrave; nevertheless, such disregard of authorities is a trivial fault, in comparison with the wholesale disregard of the genius of the style itself. Yet so it is: over-exactness as to certain particulars goes hand in hand with the most fantastical licentiousness—if that can be called fantastical which manifests not the slightest aim at fancy. It is, however, not so much the deviation from precedent that we censure in such cases, as the awkward and absurd adherence to it, or rather the affectation of adhering to what it is impossible to follow consistently as a model. Even supposing that, in regard to the architecture itself, the style could be sufficiently well kept up, still it would very ill assort with the display which it is intended to accompany. Fancy goods and Pæstan columns—plumes, velvets, artificial flowers, and Doric pillars—do not harmonise well together, nor seem to be suitable company for each other. A striking instance of such disparity between the richness of the stock it contains and the shop itself is Holmes's shawl warehouse, in Regent Street; where, notwithstanding the splendour of the *coup d'œil* of its interior, the exceedingly massive, not to say rude, Doric columns supporting the ceiling look most uncouthly lumpish amidst all the costly finery around them. Surely, a lighter style would have been far more in character; or, if pillars of that bulk were absolutely required, they might easily have been enriched. It is true, they might then have lost all resemblance to Doric columns; yet of what consequence would that have been, or rather it would have been so much the better, supposing them to be appropriate and pleasing in themselves—that is, successful inventions; and if we dare not venture upon any experiments in architectural design on such occasions, we are not likely ever to make them, when the question is to erect a building of magnitude, where every thing is expected to be perfectly *secundem artem*, and where, of course, nothing can be admitted that might possibly be sneered at as a rash innovation—a startling new idea.

Perhaps it would be some step towards improvement, were such style of design adopted for the decoration of shops as would in a certain degree accord with the stock itself and the particular business carried on. Attention to congruity of this sort would, doubtless, have suggested for the one just referred to above, a style altogether different from what we actually behold—something light, fanciful, luxuriant; and, if not professedly in the Oriental taste, that is, after an express pattern of it, yet more or less approaching to it. Characteristic peculiarity of this kind, however, would of necessity be chiefly limited to those cases—at present exceedingly rare ones—where the interior of the shop itself is fitted up, like some of the Parisian ones, with regard to effect as an architectural *ensemble*, so as to have more the air of an apartment furnished with certain articles there displayed, than of a mere warehouse where they are stowed away on shelves that entirely line the walls. The same diversity could not very well be extended to the exteriors, or shop-fronts themselves; because that would be apt to occasion a very disagreeable medley of all sorts of styles in our streets, and give them a most motley appearance. To be convinced of this, we need but look at Saunders and Woolley's shop-front in Regent Street. Whatever may be thought of the particular taste of embellishment—the so-called *Louis Quatorze*—there displayed, it is sufficiently significant; and we have no doubt that, as a design upon paper, shewn quite by itself, without any accompaniment, it made a striking and alluring appearance; yet, as actually beheld, it is as much of a blemish as a beauty,—no improvement to the street, except as affording a very showy display of window and costly articles of upholstery; and decidedly injurious to the façade where it has been introduced. The style itself is, moreover, by far too exotic and anomalous to be at all adapted for exterior architecture, even were an entire front to be designed in it so as to form a consistent composition. The Gothic style, however, that is, some varieties of it, might occasionlly be resorted to both with propriety and effect; although we are not aware of its having been hitherto applied to such purpose, except at Fairs's, in Mortimer Street, an exceedingly small, at least very narrow, upright strip of Elizabethan architecture, clever, and not a little picturesque. That the pale bronze hue given to that pretty architectural façade is attended with other advantage than that of rendering it more conspicuous, is what we will not undertake to decide; since greater variety, and quite as much propriety in regard to colouring, might have been obtained, imitating the weather-stained tints of stone and brick, with, perhaps, some of the mere ornamental parts in imitation of bronze, or other metal.

Our catalogue of *shops*, would be longer than Homer's catalogue of *ships*; and, we venture to say on our part, not very much more interesting, were we to note all that aim at being remarkable as well as fascinating. There is hardly a street of them at the west end of the town, in which one or more will not be found affording evidence of a desire to attract observation by something more than the show of goods behind the glass; but we cannot say that many of the designers have displayed much fancy or taste, or greatly taxed their invention for the benefit of their employers. In almost all of them we perceive some little, and but very little, aim at originality—a mere beginning towards it—in scarcely one instance a complete developement of a novel idea; consequently, there invariably seems to be more pretension than actual performance. Colnaghi and Puckle's new shop-front, in Cockspur Street, presents some novelty of style and detail, and is remarkable for the great projection of the cornice, which is brought forward as much as the half-octagon bay in the upper part of the house. The style itself partakes of both the *Renaissance* and the Elizabethan; and, independently of the panels with which they are embellished, the extreme piers assist the design very much, both by giving an air of stability to the *ensemble*, and a suitable termination to it. Cowie's, in Holles Street, is singular, chiefly on account of the window shewing itself somewhat like a glass-case inserted in the front, and being dark brown relieved with gilding; while the door, which is detached from it, has enormous white consoles, enriched with gilt mouldings, though all the rest are of very dark hues; a contrast of colours more *tranchant* and striking than tasteful. In the adjoining street, viz. Henrietta—Marshall and Stinton's makes a quiet sort of display with its four three-quarter Ionic columns, between which are three arches, of which the two forming the windows are each filled in with a single sheet of plate glass; which species of luxury is not rendered less singular by the extreme plainness of the windows themselves. We should recommend some liberal decoration in the spaces between them and the columns.

The new front of No. 76 in the Strand, now the "Foreign Marble Warehouse," may be cited as almost the very reverse of the preceding, being as studiously embellished as the other is studiedly kept plain. What little design there is in the shop itself, has neither much novelty nor much taste; it is the elevation above, and in a manner distinct from it, which presents a sample of an unusual mode of embellishment, it being liberally, yet not too liberally, decorated with medallions and figures in relief between the windows; and but for the disagreeable heaviness of the odd-looking cornices to the windows of the first floor, would be an agreeable composition, though susceptible of improvement in other respects besides the defect just pointed out. Had the exterior of the adjoining house been added to the design, so as to give greater width to the elevation, the effect would have been increased in more than arithmetical progression.

ON THE SUPPLY OF WATER TO THE METROPOLIS.

Observations on the past and present supply of Water to the Metropolis. By Thomas Wicksteed, *Civil Engineer. Read before the Society of Arts, May 24, 1835.*

(Continued from page 12.)

During the next two centuries, namely, from A.D. 1600 to A.D. 1800, were established several water-works of minor importance, as follow:

To the Merchant Water-works belonged three engines for raising water; one a windmill in Tottenham Court Road Fields; and two overshot water-wheels, worked by the water of a common sewer in St. Martin's and Hartshorn Lanes in the Strand; there were three mains of 6 and 7 inch bores to supply the respective neighbourhoods.

The Shadwell Water-works, erected about 1660, had first a horse-wheel, and afterwards two atmospheric engines, which supplied the neighbourhood with Thames water through two mains of 6 or 7 inch bores.

In 1694 these works, which had previously belonged to the family of Thomas Neale, Esq., were vested in a company of proprietors, who were incorporated by an act of Parliament 3rd and 4th of William and Mary. Two engines, of Boulton and Watt's manufacture, were afterwards erected; the first was one of the earliest engines made by them. When the London Docks were made, the district was much reduced in consequence, and the works were purchased by the Dock Company; and afterwards an act was obtained in 1808 by the East London Water-works Company to enable them to purchase these works, which they did. The works were in play for a short time afterwards, but were eventually given up, the supply from the Company's new works being superior.

The York Buildings Water-works, in Villiers Street, Strand, were established in 1691. The Thames water was raised for the supply of the neighbourhood, first by a horse-wheel; afterwards previous to the year 1710, they had one of Savery's engines; and a few years afterwards one of Newcomen's. Maitland says in his work, published 1756, that "the directors of this Company, by purchasing estates in England and Scotland, erecting new water-works and other pernicious projects, have almost ruined the company. However, their chargeable engine for raising water by fire being laid aside, they continue to work that of horses, which may in time restore the Company's affairs." This was true for a time, as it appears that from 1789 to 1801 this Company paid good dividends, but afterwards, in consequence of the ruinous competition that arose at that time, and for some years subsequently, a new engine was erected of 70 horses power, iron pipes laid down instead of wood, and no more dividends were paid, excepting 1*l*. per share for two years, out of the *capital;* and in 1818 the Company was ruined, the establishment broken up, and the district was supplied by the New River.

In 1775 Mr. Watt mentions an engine of Newcomen's at the York Buildings, and Mr. Farey calculated its power at about 26 horses, working 7 hours per diem, and raising during that time about 356,000 gallons to a height of 102 feet, or 3,137,000 barrels per annum. In 1810 the quantity raised at these works was only equal to 178,200 gallons per diem, or 1,511,100 barrels per annum. In 1818, before the breaking up of the establishment, the quantity raised was 762,588 gallons per diem, or 6,609,252 barrels per annum; which supplied about 2636 tenants.

The Chelsea Water-works were established in 1722 by an act of Parliament, in the 8th of George I., for the better supplying the city and liberties of Westminster, and parts adjacent, with water.

The Thames water was raised from settling-ponds, in the first instance, by a water-wheel, which was worked by the water collected in large ponds as the tide rose, and kept in until the water in the river lowered, when it was let out and worked the wheel: afterwards two of Newcomen's engines were erected, and in 1782 one of Boulton and Watt's engines,—one of the earliest erected in London.

The West Ham Water-works were set on foot in 1743, and a company was established by act of Parliament the 21st of George II., in 1747. The water was raised out of one of the branches of the River Lee by a fire-engine of about 6 horses power; these works were afterwards purchased by the East London Water-works Company, at the same time that they purchased the Shadwell works; and the power now used is a water-wheel of about 16 horses power.

Previous to the year 1756 there was a horse-machine for raising Thames water through a 7-inch pipe in Southwark, called the Bank End Water-works. A company was formed in 1758, under the name of the Old Borough Water-works Company, which, together with the London Bridge works, supplied Southwark. A steam-engine was erected afterwards; and in 1823, upon the removal of the London

Bridge water-wheels, the two works were consolidated, under the name of the Southwark Water-works, and became the property of John Edwards, Esq.

Previous to 1756 works were established at Rotherhithe. The water was raised by a water-wheel, which was worked by tide water, collected in the ditches and ponds in the neighbourhood, and kept in until the falling of the tide, when it was let out again into the river, and in its course turned the water-wheel: it supplied the neighbourhood plentifully through two 6-inch mains.

Previous to the year 1767 works were established at Lee Bridge, upon the river Lee, worked by a water-wheel, for the supply of Hackney and Clapton: they were called the Hackney Water-works, and in 1829, after which period they became the property of the East London Water-works Company, they raised about 600,000 barrels per annum for the supply of about 600 families.

In 1785 the Lambeth Water-works were established by act of Parliament 2'th of George III., to supply the district upon the south side of the Thames, exclusive of the parishes of St. George's and St. Saviour's Southwark. The water was raised from the Thames near Waterloo Bridge by steam-engines.

From the year 1800 to the present date, the following works have been established:

In 1805 the South London Water-works were established by act of Parliament 45th of George III., to supply the district on the south side of the Thames not already supplied by the Lambeth and Southwark Water-works. The works are at Vauxhall.

In 1806 the West Middlesex Water-works were established by act of Parliament 46th of George III. The works are at Hammersmith, and they supply Hammersmith, Kensington, Paddington, and Marylebone.

In 1807 the East London Water-works were established by act of Parliament 47th of George III.; they have works at Old Ford, which is their chief station for the supply of the eastern parts of the metropolis. They have purchased the Shadwell, West Ham, and Hackney Water-works, and have works and machinery for raising water at Stratford and Lee Bridge. Objections having been made in 1828 to the source from whence they raised their water, it being asserted that as the tide affected the river Lee in that part, the water "partook of the nature of Thames water," the Company, to remove all doubts, obtained parliamentary powers in 1829 to change the source of supply, and, according to the powers granted, they have, at an expense of nearly 80,000*l*., constructed reservoirs and a canal for the purpose of bringing water from a part of the river Lee which is far above the influence of the tide; so that now the water raised at Old Ford is *Lee Water only*. I mention this more particularly because it has been erroneously asserted that *Thames water* is supplied by this Company.

In 1810 the Grand Junction Water-works Company was established by act of Parliament the 51st of George III. This Company first supplied water from the Grand Junction Canal; this supply was not only limited, but was also objected to by some of the tenantry, who preferred Thames water: the works were accordingly removed to the banks of the Thames at Chelsea. This Company together with the West Middlesex and Chelsea Water-works Companies supply the western parts of the metropolis.

It appears that, in the *first* instance, when it was necessary to bring water from a distance, the Corporation were the chief promoters of all schemes for better supplying London; and never more so, than when they granted a lease of the London Bridge arches to Peter Maurice at a nominal rent; but it is probable that this supply never exceeded six millions of imperial barrels per annum—not 2 per cent. of the present supply.

Afterwards Sir Hugh Myddleton executed the plan for bringing the greatest supply to London; he was, however, ruined, the undertaking being too extensive for an individual.

And at last several wealthy men joined together, and subscribed money sufficient to execute large plans for efficiently supplying every portion of the metropolis, which is now most abundantly supplied with good water at the rate of ⅜ths of a farthing for an imperial barrel, or 36 gallons, which is the amount received by the Water Companies for every barrel they distribute, according to the parliamentary returns. This abundant supply is continued through the night, to be used in case of fires happening.

In some of the suburbs of London water is still supplied by carriers. Where it is carried in buckets from wells, it is sold at the rate of 8*d*. per barrel, or 42 times as much as when supplied by machinery; and when it is carted from the river, at 4*d*. per barrel, or 21 times more than machinery. As it is more than probable that it could not be sold at a cheaper rate in ancient times, the advantages obtained by the introduction of machinery will appear very great.

In addition to the works before mentioned, there are the Kent and the Hampstead Water-works. The Kent Water-works are situated upon the River Ravensbourne at Deptford. The machinery consists of a water-wheel and two steam-engines. The water from this river is supplied chiefly to Deptford, Greenwich, Woolwich and Rotherhithe; these works are scarcely considered metropolitan.

The Hampstead Works are small; they are the same that have been mentioned before, and are the most ancient of any of the existing works. In 1803 the New River Company supplied the tenantry.

Present Supply of Water to the Metropolis.

According to the report of the Select Committee of the House of Commons in 1831, the quantity of water raised by the eight metropolitan water-works in the year 1833 was equal to 357,288,897 imperial barrels; the number of houses supplied was 191,066, and the average daily supply was above 35 millions of gallons, or 183 gallons per house upon the average.

The following detailed account is taken from the Parliamentary Reports:

The New River Water-works supplied in 1833, 171,975,000 imperial barrels of water, 21 millions of which were raised by machinery 60 feet above the level of the New River Head, the remainder supplied by the river, which is 81 feet above the level of the Thames, a sufficient elevation to supply ⅞ths of the New River district without the aid of steam or other power. The number of houses supplied was 70,115; the capital expended from the commencement of the works has been 1,116,964*l*.; the rental received from the houses supplied with water amounted to 98,307*l*., and from lands and houses 6601*l*., or a total income of 104,909*l*.; the expenditure was 61,163*l*., leaving 43,746*l*. to be divided, or not quite 4 per cent. upon the capital. These works supply the greatest number of houses.

The East London Water-works rank next to the New River Water-works; the quantity of water supplied by them in 1833 was equal to 56,715,890 imperial barrels, all raised by machinery, under an average pressure of about 110 feet: the number of houses supplied was 46,421; the capital expended from the commencement of the works has been 594,988*l*.; the gross rental was 53,061*l*.; 22,166*l*. was divided, not 3⅞ per cent. upon the capital.

The Lambeth Water-works supplied 17,997,903 imperial barrels in 1833, all raised by machinery; the number of houses supplied was 16,682; the capital expended from the commencement of the works has been 182,553*l*.; the gross rental was 11,808*l*.; and 3,810*l*. was divided, not 2½ per cent. upon the capital.

The West Middlesex Water-works supplied in 1833, 30,000,000 imperial barrels, all raised by machinery; the number of houses supplied was 16,000; the capital expended from the commencement of the works has been 404,263*l*.; the gross rental was 45,500*l*.; their shares are valued at 68*l*. 8*s*. 9*d*., and 3*l*. per share was divided, less than 4½ per cent. upon the shares, but more than 6 per cent. upon the capital expended.

The Chelsea Water-works supplied in 1833, 23,629,500 imperial barrels, all raised by machinery; the number of houses supplied was 13,892; the capital expended from the commencement of the works has been 271,311*l*.; the gross rental was 22,906*l*.; 4,800*l*. was divided, or 1¾ per cent. upon the capital.

The South London Water-works supplied about 12,166,666 imperial barrels in 1833; the number of houses supplied was 12,046; the capital expended from the commencement of the works has been 245,306*l*.; the average per share was about 215*l*., and they were last sold at 85*l*. per share; the gross rental was 8,839*l*.

The Grand Junction Water-works supplied 32,553,850 imperial barrels in 1833; the number of houses supplied was 8,780; the capital expended from the commencement of the works has been 331,174*l*.; the gross rental was 26,151*l*.; dividend rather more than 4 per cent.

The Southwark Water-works supplied 12,250,000 barrels in 1833; the number of houses supplied was 7,100; the capital expended since 1823, when the Old Borough and London Bridge works were consolidated, has been 25,000*l*.; the works belong to private individuals, who state that the Borough Water-works did not pay 1 per cent, and the London Bridge never more than 3 per cent.

The whole capital expended since the establishment of these water-works has been 3,171,559*l*.; and the amount of dividend upon this capital in 1833 was between 3 and 4 per cent. All of these were for many years without any dividend, and frequently much lower than that before named,—seldom higher.

I think the foregoing statement will prove that the profits of the public Water Companies have not generally been very exorbitant; and that, whatever objections may be made in particular cases, great credit is due to the enterprise of those who have, for a trifling gain, risked their property for the public good.

I cannot proceed further without remarking, that in the observations

I have made, and am about to make, I am not advocating any particular interests, but merely expressing my individual opinion of a great public good; nor do I think the circumstance of my being at present connected professionally with one of the largest of the Water-works Companies should be any bar to the expression of an independent opinion. In the following observations, I can only regret that others more competent have not taken the task in hand, knowing, as I do, how many there are connected with this Society infinitely better able, from age and experience, to do justice to the subject.

That Great Britain stands pre-eminent amongst nations is not only on account of the valuable minerals in which she abounds, and which is accidental, but also on account of the industry and perseverance of her subjects enabling them to overcome the greatest difficulties, and to avail themselves to the fullest extent of the resources Nature has blessed the islands with.

The chief reason that there are larger and nobler establishments for the public good is, that in England, instead of the Government executing and controlling the large public works, enterprising individuals join together, and, each subscribing a portion of his property, execute the largest and grandest works. The only inducement is the fair expectation that the money subscribed will yield an equitable return for the risk incurred. This return is made by that portion of the community who derive advantages from the undertaking,—advantages which could not be obtained excepting by joint subscription. If any work is undertaken which, although beneficial to some portions of the community, is not to others, that only which derives the benefit pays for it; whereas, if it were undertaken by Government, in many instances the *whole* would have to pay for the *part* enjoying the benefit, or no works upon a similar plan to those which, until of late years, were peculiar to Great Britain, would be undertaken, as the acquiescence of the majority must be obtained before a wise Government would embark in any large undertaking.

This system, as every other, may be abused; but I am speaking of the system when it is properly worked, not otherwise.

The case of Sir Hugh Myddleton is one showing directly the necessity of many individuals joining together; the undertaking was too large, and the risk too great for one man, to ensure a safe return; he therefore was ruined. If in the first instance others had joined with him, a portion only of his fortune would have been lost. It is not to be expected that Companies can be formed without a fair chance of a return for the money risked: and as the benefit derived from great public works cannot be obtained otherwise, the nation, while it is doing right to guard against abuse, must, on the other hand, be cautious that, by requiring too much, it does not render the article too costly, and thus put a stop to the system. Every Company, as every individual, expects and ought to be remunerated, otherwise there is an end to companies.

There have been many abuses of the system, and a consequent suspicion of it; individuals not unfrequently most honestly undertake to expose these abuses,—it is a difficult task; care must be taken that in attempting to cure a limb the whole body is not, through ignorance, destroyed.

In determining upon the supply of water to a large district, the chief points to be attended to are, first, whether it is to be obtained at such a cost that those who risk their money to obtain it can supply it at an unobjectionable price, and at the same time be fairly remunerated; second, that the quality be good; and third, that the quantity be abundant.

On the first I have to observe, that in London, with the exception of the greatest portion of the New River supply, the water has to be raised by the power of steam to dwelling-houses situated *above* the source; and by the same power it must be forced through pipes, so that each inhabitant shall have a supply: to preserve and continue this power is the greatest source of expenditure in water-works. *If* water cannot be obtained in the *neighbourhood* at a sufficient elevation to run into the houses of the inhabitants, recourse must be had to mechanical power, or the plan of carrying water from a distance by human labour must be readopted. The power necessary is in proportion to the quantity of water required and the height to which it has to be raised. If the elevation is 100 feet, it will require double the power that it would if it were only 50 feet; if, therefore, the rivers near London are discarded, and deep springs are resorted to, the height to which the water will have to be raised will be at least 100 feet greater than the height from the rivers, and the expense will be proportionately increased, which must be met by increased payment for the water. To raise the present supply of London 100 feet high, without considering friction, a power equal to about 1480 horses will be required, working 12 hours per diem.

In addition to this, as the water supplied by the New River Company is now delivered by their river at 84 feet above the water of the Thames, taking the average pressure at 60 feet, an additional power of 130 horses, working 12 hours per diem, would be required, or a total increase of power equal to more than 1900 horses. To establish and maintain this power would require an investment of capital equal to about 1,500,000*l*. The same reasoning will apply to *filtering* the *whole* supply.

This fact must be borne in mind, that if more capital is laid out in what is, often erroneously, termed *improving* the supply, higher rates must be paid; and if those who pay for the water are not satisfied, and are willing to pay higher rates, they can have a more costly article; and that if any alteration is made in the general supply of water, which leads to increased expenditure, whether this is made by the Companies already established, or by new Companies, the case is the same,—higher rates must *eventually* be paid, whatever is done in the *first* instance; and this appears to me a statement which no unprejudiced individual can gainsay;—I am speaking of the *general* supply, not of any particular cases.

And this brings me to the second point, namely, quality. From the parliamentary inquiries lately made, it appears that owing to the improved drainage in London consequent upon the abundant supply of water which has of late years flowed into the sewers, the water of the river Thames had in that portion in which the drainage took place become inferior in quality to what it had been before. The strongest evidence upon this subject was that of Dr. Bostock, a gentleman of well known experience in the analysation of waters; he stated distinctly that the impurities of the water were mechanical, and might be separated by filtration. It would also be well to notice what proportion of the supply of London comes from this objectionable source: about 65 per cent. of the whole supply is *not* Thames water; about 22 per cent. is either taken above Hammersmith Bridge, beyond the influence of the London drainage, or is filtered; and as to the remaining 13 per cent., powers are, or are about to be obtained forthwith to change the source of supply. In the latter case delay has been occasioned by a belief, justly founded, that Parliament would have proposed a plan for their supply; and in fact, powers were refused the parties until it was determined whether this would be the case or not.

For drinking, spring water is the pleasantest; and although it may contain certain salts, which render it hard and unfit for domestic purposes, it is not in the slightest degree injurious to health. Few would prefer river water to drink, if they could obtain spring water, as the very quality of softness which renders river water so valuable for general purposes, is that which renders it flat and unpalatable, namely, the absence of salts, which causes the water to be hard.

Thirdly, as to quantity; that this is a point of very great importance may easily be proved. In 1833, 191,066 houses were supplied with water; the quantity of water raised was 35 millions of gallons daily. Supposing each house required 9 gallons per diem for drinking in the simple form, or otherwise, this would amount to $\frac{1}{20}$th of the whole quantity, or 5 per cent.; and the remaining $\frac{19}{20}$ths, or 95 per cent., is required for washing, cleaning sewers, watering gardens, and running down the channels in the public streets, and a portion for manufacturing purposes, and for fires.

The Water Companies are bound to give an abundant supply in case of fire; and during the time that the cholera morbus raged, a gratuitous supply was given, and the water was allowed to run out of the mains down the streets, alleys, and courts whenever required;—in the first instance insuring the lives and property of the public against fire; and in the second, preventing the spread of disease by rendering the whole, but especially the thickly populated parts, of the Metropolis healthy.

If, therefore, so small a quantity is required for drinking, and so large a quantity for other purposes, it would be a very imperfect scheme which sacrificed the latter for the former.

If a purer water *can* be obtained, and *is required*, either from deep springs or by universal filtration, as this cannot be done excepting by an enormous outlay of capital, and a proportionate increase of rates, which is preferable,—that the whole 35 millions used for all purposes should be filtered; or that for a short season every year, when the rivers are discoloured, each inhabitant should have a portable filter, which may be obtained for 20s., and filter the twentieth part? That the latter would be the cheapest to the consumer I am quite satisfied. I am of course speaking now of that portion of the supply out of the influence of the London drainage, and which is only mechanically affected in rainy seasons, at all other times being clear and free from mechanical impurity. I say mechanical impurity, in contradistinction to chemical impurity: the first may be got rid of by deposition or filtration; the second cannot be got rid of but by changing the source. The evidence, however, given before Parliament shows that none of the water supplied to London is so *chemically* impure, as to be in the least degree injurious to health.

That all inquiries into abuses are good and desirable there is no denying, but it appears to me that exaggerated statements have been made of the abuses in Water Companies, and that it is not generally borne in mind that if any increased outlay is necessary it may be effected at much less cost, eventually, to the tenantry, by those whose works are established and whose experience is great, than by others; and the fact that great works have lately been executed by some Companies, and that more are about to be undertaken by others, without increasing the rates, shows a disposition on the part of those engaged in them to make the good of the public their first object. That some are obliged to increase their rates, upon a greatly increased expenditure, arises from the difficulties being so great that the Company could not be carried on without it, and unless other parties will undertake, and *be bound under sufficient securities*, (to be determined by Parliament,) to supply such districts at lower rates, an increase should not be objected to.

I am fearful I have too long occupied the time of the Society in observations which, as they are those of an individual only, cannot be of much importance; but thanking them for their kind intention, I will conclude by an explanation of the mode in which a town is supplied with water according to the present system.

If any town be so fortunately situated that a supply of water may be had from springs in the *neighbourhood*, of good quality, abundant in quantity, and at a sufficient elevation to overcome the friction created by the passage of the water through the pipes, and to allow it to run into the upper stories of the dwelling-houses, the arrangement for the supply will be simple, and the annual expense beyond the interest of the capital expended will be trifling. It is, however, but seldom that such is the case.

In general the water has either to be raised from the rivers in the immediate neighbourhood at a great and continual expense of power; or, where there are no fresh-water rivers within a practicable distance, from deep wells; in which case the necessary power will be doubled; or, lastly, should there be a river in the neighbourhood, and it should be desirable to avoid the continual expense of steam power, it may be effected by bringing a cut from such part of the river that the elevation obtained by going a considerable distance up the stream produces a sufficient head without the aid of machinery, as in the case of the New River. The head is obtained thus: the natural fall of the river from whence the water is taken is so much greater than is necessary to produce the required velocity for the water through the canal, that the difference in levels makes the required head.

If an opportunity is afforded of adopting either the mode of bringing it from a distance by means of a canal, or by pumping from the river by steam power, the choice will be determined by the result of the estimate of the cost. The canal will cost more than the steam power in the first instance; and to determine which is the least expensive, the interest of the capital expended added to the annual expense of keeping the canal in repair must be compared with the interest of capital expended for the steam power added to the annual amount for repairs, *and the cost of fuel and wear and tear of the steam power.*

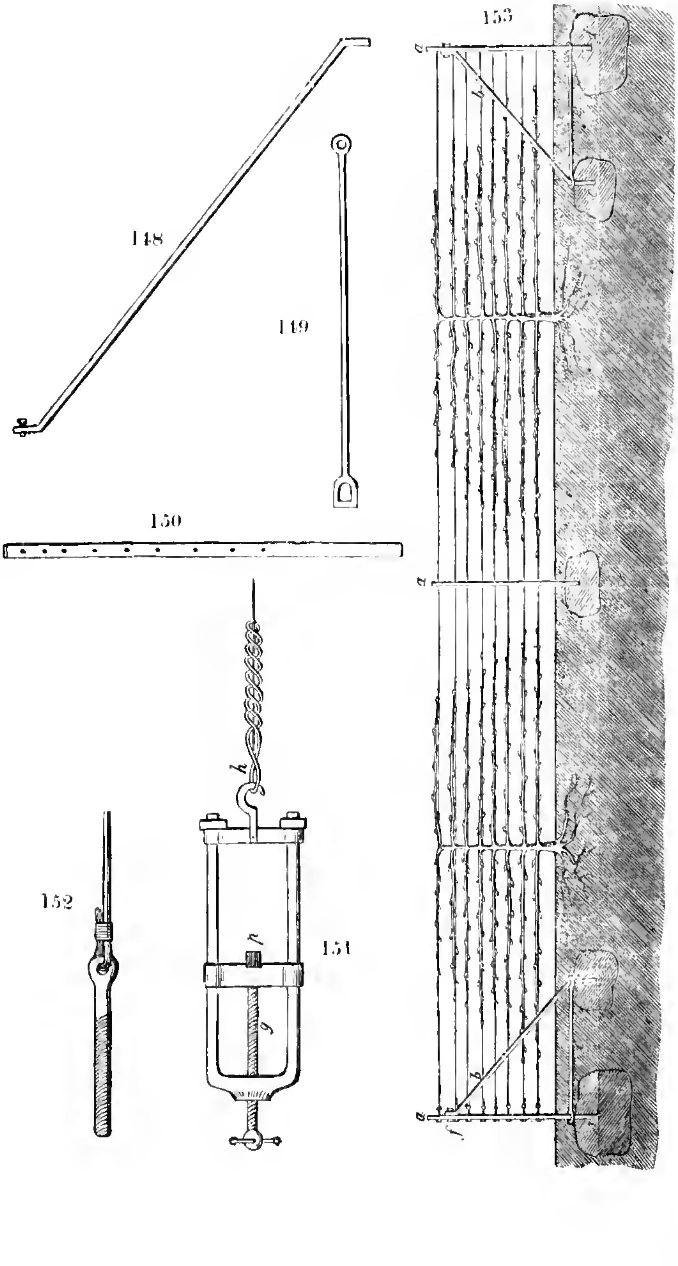
In small towns one line of pipes communicating with the source passes through the streets, and each inhabitant is supplied at the same time. In larger towns, where the number of houses to be supplied is great, and the distance that the water has to travel is also great, recourse is had to the following contrivance: in the principal streets mains are laid, which convey the water from the source; and branching from these mains, other smaller-sized pipes are laid, called services; at every point where the services branch from the mains a cock is attached, by means of which the communication with the main is either opened or shut off; from the services small lead pipes branch to each dwelling-house, and whenever the communication is opened with the mains, which *are always charged*, the houses whose lead pipes are joined on to the service receive a supply of water.

The necessity for such an arrangement will be made obvious by the following statement:

When water is forced through pipes either by a natural or artificial head, or by steam or other power, friction is created in proportion to the velocity of the water and length of the line of pipes. As the distance increases, the power must either be increased or the velocity reduced; the shorter the distance, the less the power required to overcome the friction; if, therefore, it is necessary to exert a great power to force the water to the extremities of an extensive district, that they may be properly supplied, it is very evident that the power which is exerted near to the source, not being required to overcome so great an amount of friction as at the extremities, must be applied to increase the velocity of the water through the orifices near the source; and if, therefore, such an arrangement as the one herein before mentioned were not adopted, the effect would be that those houses which were near the source would have a superabundant supply, while those at a distance would have a very small supply, if any; but, by means of the system mentioned, when the inhabitants near the source have received their supply the cocks on the services are shut down, and the water in the mains passes on to supply the services at the extremities, which will have a sufficient supply, because the water, not being used before, must pass on to the extremities. That each may have an *equal* supply, those that are near the source have the communication opened with the main for a shorter time than those at a distance, in proportion to the velocity with which the water is delivered.

In addition to this, on every line of mains and services orifices of about 2 inches diameter are made at certain distances, which are filled up with what are termed "fire plugs," being nothing more than wooden spigots made to fit the orifices; these are easily fitted and as easily removed, and in case of a fire they are started, and a supply is given directly. The strength of this supply is regulated by means of the system before mentioned; thus, by closing the service cocks in the other parts of the district, the whole force of the water may be concentrated in that part where the fire has occurred.

WIRE FENCES.



WIRE FENCES.

(From the Gardener's Magazine.)

At an ordinary meeting of the Horticultural Society of London, the following letter to the secretary from Mr. W. B. Booth, was read, upon the mode of constructing wire fences for training espalier fruit trees upon, and for other purposes.

"*Carclew, January* 29, 1839.

"Sir, I beg to hand you the following particulars respecting some wire trellises lately erected here, which you may, probably, not deem unworthy of submitting to the notice of the Horticultural Society.

"The object for which they are intended is the training of espalier fruit trees; and it occurred to me, in the course of erecting some wire fencing to divide a portion of the park, that a similar kind of erection might be advantageously introduced into the kitchen-garden, which would answer the same purpose as the expensive wooden or cast-iron trellises usually met with in those places where the espalier mode of training is adopted. I accordingly submitted the plan to Sir Charles Lemon, who has since had it carried into execution to a considerable extent.

"Wire erections of the kind I am about to describe are not uncommon, I believe, as fences, in some parts of the kingdom; but in Cornwall it is only within the last few years they have been introduced. Mr. Gilpin, in his excellent *Hints on Landscape-Gardening*, p. 217, has noticed the wire fence as being best suited for those parts near to the house, or to the approach, but he has not shown the manner in which it may be erected. The accompanying sketches and details will, I trust, supply this deficiency, and enable any one who may be desirous of erecting a wire fence or trellis to do so, with the assistance of a mason and blacksmith, at a very moderate expense. The wire used is known as No. 32. It is about a quarter of an inch in diameter, and is put up in large coils. Each wire measures from 115 ft. to 120 ft. in length. The main upright posts fig. 153 *a a* are of iron, 1¼ in. square, and from 5½ ft. to 6 ft. high, with holes 6 or 7 inches apart for receiving the small screws and nuts, to which the wires are attached in the way shown at fig. 152. At the opposite end the wire is secured by being bent a little at the point, and having a small wedge driven over it in each of the holes of the upright. Both these main posts are 4½ ft. above the level of the ground, and are fixed beneath the surface in large rough blocks of stone *d e*, with iron wedges, which are more convenient, and answer the purpose quite as well as if they were run in with lead. The stay-bar is round, and 1¼ in. in diameter. It varies in length according to the inclination of the ground, but when the latter is nearly level it is about 7 ft. long. The upper end is flattened, and beveled, so as to square with the upright, to which it is fixed by means of a screw at *f*. The lower end is only a little bent, that it may fit into a somewhat smaller block of stone *e* than the one at *d*. The connecting bar *c* is square or round, and need not exceed an inch in either case. It will also vary in length, according to circumstances. On a nearly level surface it must be about 5 ft. long, and have an eye at each end large enough for the end of the post and stay to go through. In addition to this, there are uprights of one-inch flat bar by half an inch in thickness fixed in stone, at 30 or 40 ft. apart, or even nearer if necessary, for the purpose of stiffening the trellis.

"In the erection of this kind of trellis, it is requisite to have an instrument for drawing the wires like the one represented at fig. 151 to the scale of an inch to a foot, which may be made without much difficulty. The one I have sketched was constructed by our own blacksmith, and is a very efficient contrivance for the purpose. After the stones are bored and set in their places, with the earth firmly rammed around them, the next thing to be done is to fix the main post *a*, and wedge it tight. It ought to lean about an inch back from the perpendicular, to allow for its giving a little when the whole strain of the wires comes upon it, which will bring it upright. The connecting bar *c* is then slipped down over it, while the lower end of the stay-bar *b* is put through the other eye and into the stone *e*, and the upper end screwed to the main post at *f*. The triangle from which the wires are to be stretched is then complete. A similar triangle must be made at the opposite end, and against the main post of which *p* the instrument above noticed is to be placed for the purpose of drawing the wire. This is done with great facility by means of a double piece of rope-yarn twisted several times round the end of each, and hooked, as shown at *h*. The screw *g* is then worked until the wire enters its proper hole in the post *p*, when it is bent and secured by a wedge, as already stated. The nuts on the bolts fig. 152, at the end from which the wires were drawn, are then screwed up a little, so as to make all the wires as tight as possible. The cost of the whole averages from 1*s*. 6*d*. to 2*s*. per yard.

"I have been thus minute with the details of the trellis and the mode of erecting it, in order that those who approve of it may be able to have others erected on the same plan, for either of the purposes to which it has been successfully applied at Carclew.

"I am, Sir, your very obedient servant,

"Wm. B. Booth."

STEAM BOAT PROPELLERS.

Sir—Whatever effect the experiments of Geo. Rennie, Esq., on steam-boat propellers, may have on the public generally, allow me to say, that I consider conclusions more erroneous were never before formed from any experiments, and with your permission I will attempt to prove, that the assertions relative to the superiority of the spear-shaped paddles are utterly without foundation. And what are these assertions, and what are we called on to believe? Why, that the floats of a paddle-wheel, when made in the shape of a trapezium, (with the acute ends down,) present double the resistance to the common rectangular floats with three times the width and equal area! A most important discovery certainly; and pray how is it that all our writers and experimenters on practical hydraulics have neglected to make known to us this peculiar but important property of the trapezium? Is it not for this simple reason, and this only, that they never could have discovered that such a property belonged to it? Indeed, it is a most glaring inconsistency to imagine that a flat surface, fashioned into a trapezium, can present double the resistance to a rectangular surface of equal area: we say that there is no authority whatever for the assertion, and happily for us Mr. Rennie has placed the proof within our reach.

We find, in the second table of experiments, (p. 25 of the Journal,) that a paddle-wheel of 3 ft. 3 in. diameter, with rectangular floats $9\frac{1}{2}\times4$ in., the total area of floats immersed being 228·8 sq. in., propelled the boat at the rate of 2·8 miles per hour, with 41·8 revolutions of the winch per minute. Also, that with trapezium-shaped floats, $9\frac{1}{2}\times4$ in. (the acute ends down,) and immersed area 107 sq. in., with a wheel 3 ft. 10¾ diameter, and 47·5 revolutions per minute, the same boat was propelled at the rate of 2·9 miles per hour.

In the first case, *i. e.* with rectangular floats, we shall find on calculation, that the centre of pressure, (assuming it in each case to be the centre of the floats,) travels at the rate of 382·9 ft. per minute, or 4·35 miles per hour, and the velocity of the boat is stated to be 2·8 miles per hour; the difference between these two quantities $(4{\cdot}35-2{\cdot}8)=1{\cdot}55$ miles per hour: this is the rate at which the floats, with an area of 228·8 sq. in. recede in the water, to obtain resistance sufficient to propel the boat at the rate of 2·8 miles per hour.

In the other case, *i. e.* with trapezium-shaped floats, we shall find, in the same way, that the centre of pressure travels at the rate of 466·3 ft. per minute, or 5·3 miles per hour, and the velocity of the boat being only 2·9 miles per hour, shows that the floats, having an area of 107 sq. in., recede at the rate of 2·4 miles per hour, to produce an equal resistance, (or nearly so) to the rectangular floats.

A writer in that excellent and useful publication, the Mechanic's Magazine, states the propeller to be "an important modification of the old paddle, being an ingenious application of a most simple and beautiful principle in nature," and mentions also the observation of the talented inventor, Mr. Rennie, "that nature never attains her ends but by the best and most efficacious means," meaning, of course, that the propeller in question is "the best and most efficacious." As Mr. Rennie seems to have followed *nature* so closely in his invention, it seems passing strange that he should have overlooked another of her principles, equally simple and important, viz. that of *the resistance opposed to the motion of a body through water being as the square of the velocity*: had he tested the performance of his floats by this simple law, he would have seen at once on which side the efficiency rested.

With the rectangular floats, we have seen that the recession, or the velocity of the floats through the water, is 1·55 miles per hour; the square of this is $1{\cdot}55\times1{\cdot}55=2{\cdot}4025$.

The recession of the trapezium-shaped floats is also shown to be 2·4 miles per hour, the square of which is $2{\cdot}4\times2{\cdot}4=5{\cdot}76$.

The *area* of the immersed floats necessary to produce an equal resistance in each case, is of course inversely as their velocity; and taking the area of the rectangular floats moving through the water at the rate of 1·55 miles per hour, at 229 sq. in., we find, by simple proportion, the area of the *same sort of float*, necessary to produce an equal resistance when moving through the water at the rate of 2·4 miles per hour, to be only 95·5 sq. in. for 5·76 : 2·4025 : : 229 : 95·5. Hence we see plainly, that had the *rectangular* floats been of equal area *only* with the trapezium-shaped floats, and *travelled at the same velocity*, the resistance would have been quite as great, if not greater; for the area of the immersed trapezium floats is stated to be 107, and the calculation shows that 95·5 sq. in. would have been sufficient with rectangular floats.

But we have no occasion to stop here; Mr. Rennie has tried the merits of the two kinds of floats on a larger scale, (viz. with the "Pink" steamer,) and we shall be able to show, that instead of being superior, the trapezium-shaped floats prove themselves to be infinitely inferior to the rectangular, as the experiments are made on a larger and fairer scale.

Pursuing the same method of calculation, we find that in the wheel with rectangular floats, the centre of pressure travelled at the rate of 754·8 ft. per minute, or 8·56 miles per hour, whilst the boat only travelled at the rate of 6·7 miles; then 8·56 — 6·7 = 1·86, for the recession of the rectangular floats with 635·6 sq. in. surface. The centre of pressure of the trapezium-shaped floats travelled at the rate of 829 ft. per minute, or 9·41 miles per hour, and the boat 6·34; then 9·41 — 6·34 = 3·07 for the recession of the trapezium floats per hour, having a surface of 432·25 sq. in. The square of 1·86 = 3·4596, and the square of 3·07 = 9·5249, then 9·5249 : 3·4596 : : 636 : 231 sq. in. Here we again see, that had the *rectangular* floats had an area of only 231 sq. in., and *travelled at the same velocity as the trapezium*, the resistance would have been equal! Whereas it appears by the experiment, that the area of the immersed trapezium-floats, was 432 sq. in., or (432 — 231 =) 201 sq. in. *greater* than would have been necessary with *rectangular* floats.

Thus far, then, we think we have proved all that we attempted, and now let us ask, what are the other advantages besides a reduced area, which are said to be derived for the use of the trapezium-shaped floats? A reduction of two-thirds in the width of the paddle-wheels and boxes. Having clearly shown that no advantage whatever is gained as far as the *area* of the immersed floats is concerned, but rather loss of power incurred; what authority is there for asserting that placing the floats endwise is advantageous? On the contrary, do not the experiments prove this modification to be as good as disadvantageous? for we see that when the obtuse angle was down, a surface of only 403 sq. in. was sufficient to propel the boat at the rate of 2·8 miles per hour, with only 16·5 turns of the winch, and a 3 ft. 6½ in. wheel; but when the acute angle was down, the velocity was only 2·9 miles, with 17·5 turns of the winch per minute, and a 3 ft. 10¾ in. wheel. In fact, there is just as much authority for stating, and I make bold to say, that the results would be found equally as favourable, were the common rectangular floats also placed endwise, as the trapezium floats are when in that position.

The disadvantages of the common paddle-wheel are universally acknowledged, and it would therefore have been much fairer, had Mr. Rennie compared the effects of the trapezium floats with the cycloidal or the vertically-acting paddle.

Above all, it may not perhaps be rude to ask, who are the competent judges and witnesses who are said to "have seen the experiments repeated again and again and *tested* them?" I think I may venture to say that Professor Barlow was *not* one of them, though he is said to approve of the plan *theoretically*.

In sending you my views on the subject, I trust I shall not be accused of any motive unworthy of the subject, or of endeavouring to cast a slur over the efforts of the talented inventor; but Mr. Rennie should recollect, that assertions coming from so high a quarter, are much more likely to mislead than when made by an obscure individual. If I am wrong in my views and calculations, it will be easy to discover the seat of error and thus elicit truth, and I shall then be the first to acknowledge it; but should this letter be the means of preventing a needless expenditure of money, I trust that those interested will consider that, instead of inflicting an injury, I have conferred on them a benefit.

I am, Sir,
Your obedient servant,
J. L.

Yewsley,
Jan. 9th, 1840.

TRAVERSING SCREW-JACK.

Fig. 1.—Side view.

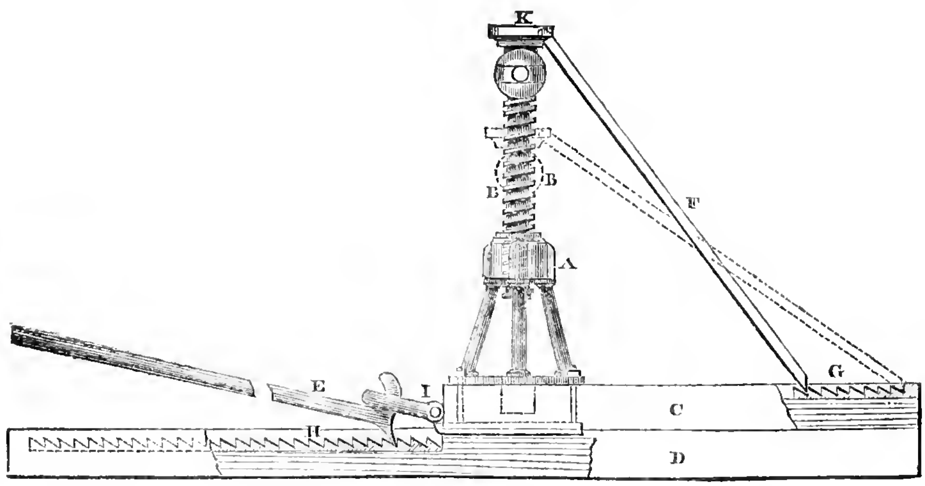


Fig. 2.—Plan.

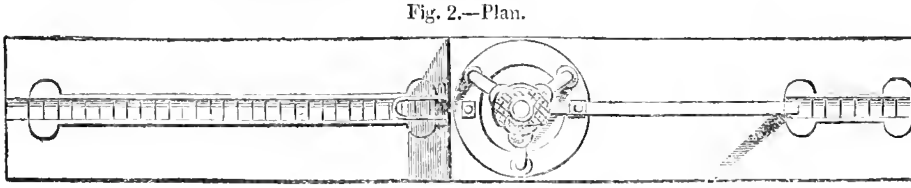
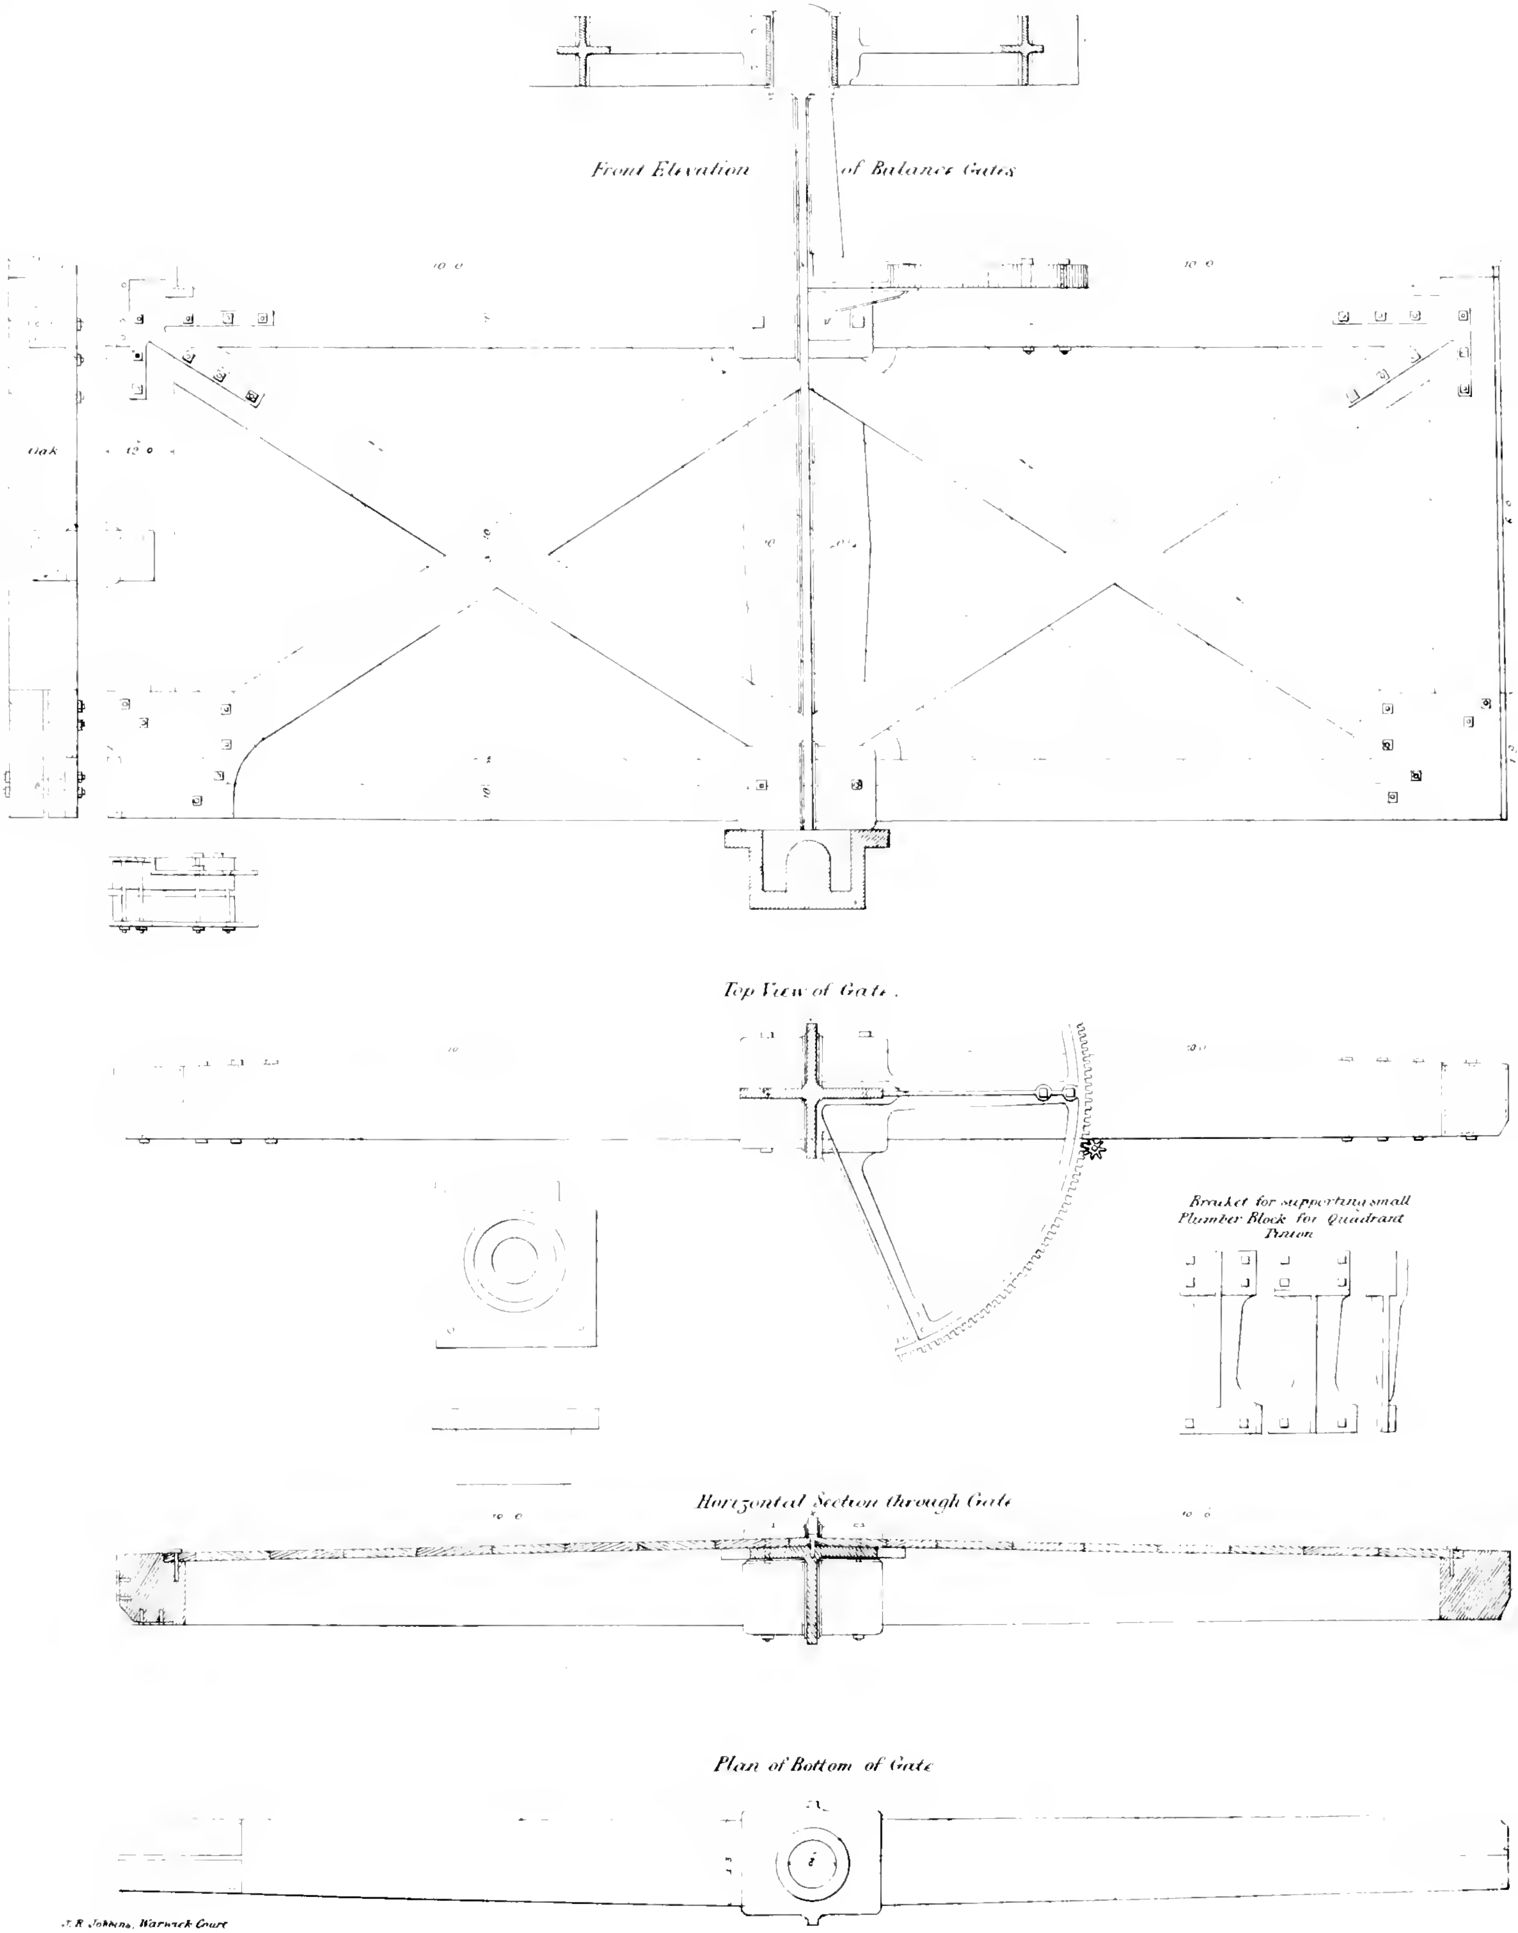


TRAVERSING SCREW-JACK.

FIGURES 1 and 2 exhibit the screw modification. The screw-jack *a* is bolted to the plank *c*; at the other end of the plank is fixed the rack *g*, in which the toe of the strut *f* advances as the screw *b* is elevated; the strut works in a joint in the follower *k*: the position of the strut when the screw is depressed is shown by the dotted lines. The object of this strut is to relieve the screw of the violent cross strain to which the apparatus is subject, when the engine or carriage is pulled over by the lever; which strain is entirely transferred to the strut, and the screw has merely to carry the load.

The operation of traversing the jack is as follows: by hooking the link *i* upon the hook of the lever *e*, the toe of the lever being inserted into a ratch of the rack *h* of the lower plank, when a man, bearing down the end of the lever, drags the apparatus and engine or carriage towards him with great facility; the same lever is used to turn the screw, and to produce the traverse motion. By this apparatus an engine of 16 tons weight has been replaced upon the rails in five minutes by the engineer and stoker alone; thus those delays which are the subject of so much annoyance and loss to railway proprietors and the public, need not happen in future; the apparatus is exceedingly portable and cheap, and no train ought to be allowed to go out without its being sent along with it; it may be carried either upon the tender, or upon some other place which may be selected for it.

EAST LONDON WATER WORKS.



J. R. Jobbins, Warwick Court

APPARATUS FOR RAISING WATER.

Patented by M. De L'Osier.

ACCOMPANIED BY AN ENGRAVING, PLATE II.

Extract from Specification.

Figure 1, plate 2 is a vertical section of the apparatus, figure 2 is a plan of figure 1. A is the tube leading from the steam boiler, B is the stop cock to shut off the steam when not required. C the tube which I call the vacuum tube. D and E tubes through which the air flows. F the tube into which the steam passes in its escape to the chimney or into the open air, it is also through this tube that the air passes; *a* represents the openings for the steam in the pipe. F, shewn in section at figure 3, two of these openings a e circular, parallel and concentric; the two others are plain, and their direction tends to the common centre of the circles, generating from the two others. The sectional form of the tubes may be varied to any form required. The interior diameter of the tube D is equal to from 14 to 15 of that of E, and the diameter of E of 15 to 18 of the tube F.

The size of the opening at *a* is about one-tenth of the size of tube F, these proportions may be varied, but I have found them produce good results in working with a pressure of steam equal to five atmospheres. The pressure may be increased or decreased by the regulation of the opening *a*, X X are the cylinders containing the principal parts used in the apparatus. K is a vacuum chamber, I I pipes communicating between the receiver K and the cylinder X X; M the cock in the pipe C, S T are gauges to ascertain the state of the rarefied air.

Having described the parts, I will now show the manner of putting it into operation. Steam being generated at a pressure of five atmospheres, the two cocks B and M being closed, on opening the cock B the steam will flow through the opening *a*, its continued passage through the tube F carries away the air in the cylinder X X, and produces a partial vacuum in K, the mercury of the gauge T will rise to the height of 50 or 55 centimetres above the cup, then on opening the cock M, the air in the pipe C will rush through the pipes D E without materially altering the state of the partial vacuum in the cylinder X X, and of the chamber K with which it is in communication, and the mercury in the gauge T instead of being depressed will rise some centimetres higher, the state of the vacuum will be indicated by the mercury at 30 centimetres above the cup. With this apparatus you can maintain a constant partial vacuum or removing of air in any recipient. I will now proceed to describe another modification of the apparatus, there being two vacuum vessels used in place of one.

Figure 4 is a vertical section, and figure 5 a plan of the same. A the tube leading to the steam boiler, B the cock to shut off the steam when not required, C the pipe communicating with the apparatus from which atmospheric air is to be withdrawn, D and E tubes through which the air flows, F tube into which the steam flows, and it is also through this tube that the air from the tubes D and E flows with the steam, *a* is the opening for the escape of the steam shown full size at figure B, G tube into which the steam and the air come from the part of the apparatus to be now described; R R is a tube leading to the vacuum chamber O, Q conical tube communicating with the chamber O, through which the air passes into the tube G by the pipe R, H is the escape pipe for the steam and air into the atmosphere, K and L are the air vessels or receivers, I I and Y are pipes connecting the receivers K and L to the cylinders X and P, S T and U are the gauges indicating the different states of the rarefied air, X X and P are the cylinders.

The operation of this apparatus is as follows:—The steam being generated to a pressure of five atmospheres, and the three cocks B M and N being closed, on opening B the steam will flow through the orifice *a*, by the continued action of the steam through the tube the air withdrawn from the cylinder X and the chamber K, and the mercury will rise in the gauge to 50 or 55 degrees above the cup, and there remain. On opening the cock M a constant withdrawing of air will take place with considerable velocity, at the same time the state of vacuum in K X will not be materially altered, and the mercury in the guage T will be raised higher, the continued action of the steam and air through the tube G rarefies the air in the receiver L, and in the cylinder P, and the mercury in the gauge U rises to 40 centimetres above that of its cup, and is kept there on opening the cock N, the air issuing from the chamber in connection with the tube R will flow through the conical tube Q into the tube G, the state of the air in the receiver L and the cylinder P is not at all changed, but the mercury in the gauge S will rise 30 centimetres, fresh supplies of air can be admitted as explained in the description of figures 1 and 2. A third air vessel may be used in a similar manner to the second when required, by admitting the atmospheric air through the pipes R R.

Figure 6 is a plan of the apparatus suitable for raising water from one level to another when worked by either of the apparatus shown in figures 1 to 5. Figure 7 is an elevation of the same, these having been previously described in the preceding drawings, I have not thought it necessary to repeat the description. Figure 8 is a vertical section of the exhausting or draining machine, from a line drawn from P to Q shown at figure 9. Figure 9 is a plan of the stage No. 1, as shown at figure 8, from a line drawn from N to O; S S S are the receivers placed one above the other at equal distances. T T T are the ascending tubes terminating in the receiver S; the lower part of the tube T of the stage No. 1 is placed on the well or other source of water Y Y, and the lower parts of the other tubes are placed in the receivers S. The number of these stages may be increased or decreased according to the height that the water is required to be raised. At the top of each of the ascending tubes T there is a valve Y; Z is the tube through which the air is withdrawn, the lower end of the tube is open and plunged in the water of the well Y Y, it is connected with the pneumatic apparatus by the tube K, and with the recipients S S S, by the small tubes U U U; X X X are the floats, and V V V are the air valves. In the top of the upper receiver S is attached a bent discharge tube W, closed by a valve W'; R is the reservoir for the water when raised, Æ shows where a pipe may be fixed to conduct the water to any place required.

To put this machine into operation, the cock E, figures 6 and 7 of the apparatus, is to be opened, the air and steam flowing into the atmosphere by the tubes F F, and the mercury of the gauge I will rise to 50 or 55 centimetres above its cup. The cock L is then opened, and the air contained in the interior of the exhausting machine will flow through the tube K across the pneumatic apparatus with great speed, at least 200 centimetres per second, and will flow into the atmosphere with the steam. The discharge of the air across the apparatus does not in any way affect the state of the vacuum, as may be ascertained by the mercury in the gauge I always remaining at the same height. The height of the mercury in the gauge M will always indicate the state of the air contained in the exhausting machine when it is about 31 or 32 centimetres; the receiver S of the stage No. 1 is full of water drawn from the well Y Y, the float X will then raise the small valves V V, and close the orifice U for the discharge of the air against which it will be held fast, the atmospheric air being admitted through the small openings of the valves V, the valve Y closes, and the pressure on the water in the receiver forces it up into the receiver S of the stage No. 2. The same operation is performed in the stages No. 2 and 3 as that described with regard to No. 1, it is not therefore necessary to repeat the description. The air valves of the stages No. 1 and 3 are opened by their floats at the same time that they are closed in the stage No. 2, they will then be restored to their original position. The water when raised to the upper receiver at the stage No. 3, flows through the tube W into the large reservoir R, and the valve W' is raised to allow it to pass freely, during this time the water again flows into the receiver of the stage No. 1. Besides this tube W in the receiver S of the stage No. 3, there is another which is not shown in the drawing, the object of it is to regulate the opening of the valve by means of a screw, in order to regulate the flow of the water in such manner that the float X shall press against the air escape pipe, at the same time that the float of the stage No. 2 raises its air valves, and the float of the stage No. 1 presses against the opening of the air escape pipe. In order that the floats should properly perform the functions that are assigned to them, they must be so constructed that the power which they require by the quantity of water displaced, will be sufficient to raise its proper weight, and to overcome the resistance which the pressure of the air exercises upon the air valves, and the weights of these same valves, and also that when the receivers are empty, their weight allowing for the part which is sustained by the water in the tube in which they are placed, will be sufficient to overcome the resistance of the pressure of the air, which keeps it pressed against the opening of the air escape pipe. The air escape pipe Z Z is placed in the water of the well Y Y, in order that if the water in the receiver (S S S) should flow into it through the tube U U, it may fall down into the well. This machine may also be worked by using any number of air vessels that may be required.

Artesian Well.—The boring instrument now at work for the Artesian well in the abattoir at Grenelle has reached the depth of 508 metres, or 1,666½ feet. The earth brought up is still a greenish clay. It requires 4 horses and 12 men to keep the apparatus in action; and it is daily hoped to see water burst up. The temperature increases a degree in warmth for every 30 yards penetrated downwards.

REVIEWS.

Repton's Landscape Gardening and Landscape Architecture, a New Edition. By J. C. LOUDON, F.L.S. London: Longman and Co., 1840.

HUMPHRY REPTON.

Humphry Repton was born at Bury St. Edmond's, May 2d, 1752, of a respectable family, and was originally intended for trade. At an early period he was thrown into contact with the Hopes of Amsterdam, a circumstance which perhaps decided the natural bent of his mind, and confirmed that love for the arts which forbade any other pursuit. After a long contest against his favourite studies, about 1788 he decided upon adopting the profession of a Landscape Gardener, a title which he created and maintained against those who decried its novelty. What was his success in this career it is unnecessary for us to mention, England abounds with his works, and he has left behind him a name which will live when the traces of his labours have vanished. His personal character powerfully influenced him in his artistical career, mild and amiable in his disposition, the same feelings seemed to influence his designs. Grandeur perhaps he rarely attained, but in producing scenes of cultivated and placid beauty, speaking at once of comfort and of wealth, he stood without a rival. He seemed as it were the genius born for cultivating the gentle slopes, and verdant meads of the sea-girt island, ever inspired with that love of the beautiful in nature, which marks the English character, fertile in expedient, he waged perpetual battle against the rude and unpicturesque, and powerfully contributed towards promoting that taste in landscape which has rendered this country the model of surrounding nations.

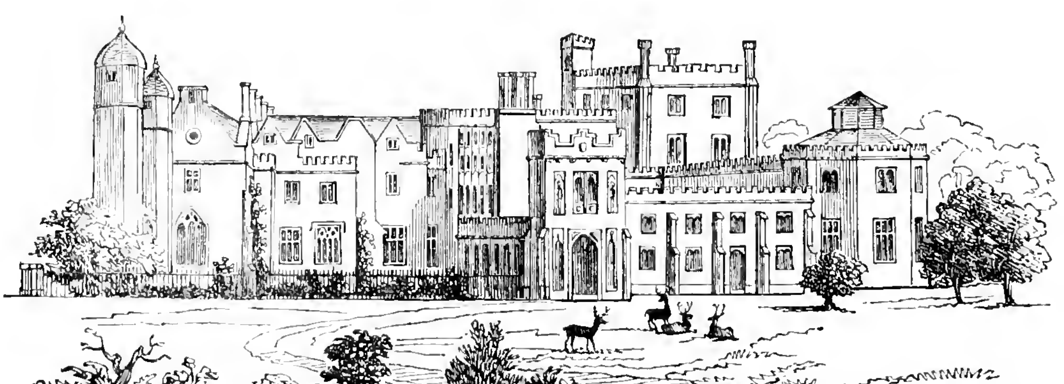
Repton's works consist of an agglomeration of fragments dispersed over one folio and three quarto volumes, now, however, collected by Mr. Loudon into one volume octavo. The service which Mr. Loudon has rendered by this task, cannot be too highly appreciated by the public, for he thus codified (as Bentham would have called it) the most valuable materials on the theory and practice of the art. Throughout these works a continual flow of originality of thought and beauty of idea seems to run from the pencil and pen of Mr. Repton, while the manner in which he exhibits its own personal interest in the subject give such a tone of identity as to resemble rather the warm breathing words of a professor than the cool notes of a closet writer. Repton is always present before us, and yet, instead of charging him with egotism, we receive him as a kindly guide and instructor. There are few portions of Milton more interesting than that where alluding to his blindness, we are personally introduced to an author whom we admire. Thus Repton alludes to some of his grievances.

"I cannot help mentioning, that, from the obstinacy and bad taste of the Bristol mason who executed the design, I was mortified to find that Gothic entrance built of a dark blue stone, with dressings of white Bath stone; and in another place, the intention of the design was totally destroyed, by painting all the wood-work of this cottage of a bright pea-green. Such, alas! is the mortifying difference betwixt the design of the artist, and the execution of the artificer."

"Such is the horror of seeing any building belonging to the offices, that, in one instance, I was desired by the architect to plant a wood of trees on the earth which had been laid over the copper roofs of the kitchen offices, and which extended 300 feet in length from the house."

To show the judicious observations of Mr. Repton relative to the architecture and alterations of old buildings, we select the following extracts from different parts of the work before us, and through the liberality of Mr. Loudon, we are enabled to give a few of the valuable illustrations.

FIG. 2.—ASHTON COURT.



The old part built in the reign of Henry VI. The new part added in the reign of George III.

"The annexed engraving of Ashton Court, fig. 2, furnishes an example of making considerable additions to a very ancient mansion, without neglecting the comforts of modern life, and without mutilating its original style and character.

"This house was built about the reign of Henry VI., and originally consisted of many different courts, surrounded by buildings, of which three are still remaining; in all these the Gothic windows, battlements, and projecting buttresses, have been preserved; but the front towards the south, 150 feet in length, was built by Inigo Jones, in a heavy Grecian style; this front was designed to form one side of a large quadrangle, but, from the unsettled state of public affairs, the other three sides were never added, and the present long front was never intended to be seen from a distance: this building consists of a very fine gallery, which has been shortened to make such rooms as modern habits require; but it is now proposed to restore this gallery to its original character, and to add in the new part, a library, drawing-room, eating-room, billiard-room, with bed-rooms, dressing-rooms, and a family apartment, for which there is no provision in the old part of the mansion. It is also proposed to take down all the ruinous offices, and rebuild them with the appearance of antiquity, and the conveniences of modern improvement.

"A general idea prevails, that, in most cases, it is better to rebuild than repair a very old house; and the architect often finds less difficulty in making an entire new plan, than in adapting judicious alterations: but if a single fragment remains of the grandeur of former times, whether of a castle, an abbey, or even a house, of the date of Queen Elizabeth, I cannot too strongly enforce the propriety of preserving the original character of such antiquity, lest every hereditary mansion in the kingdom should dwindle into the insignificance of a modern villa."

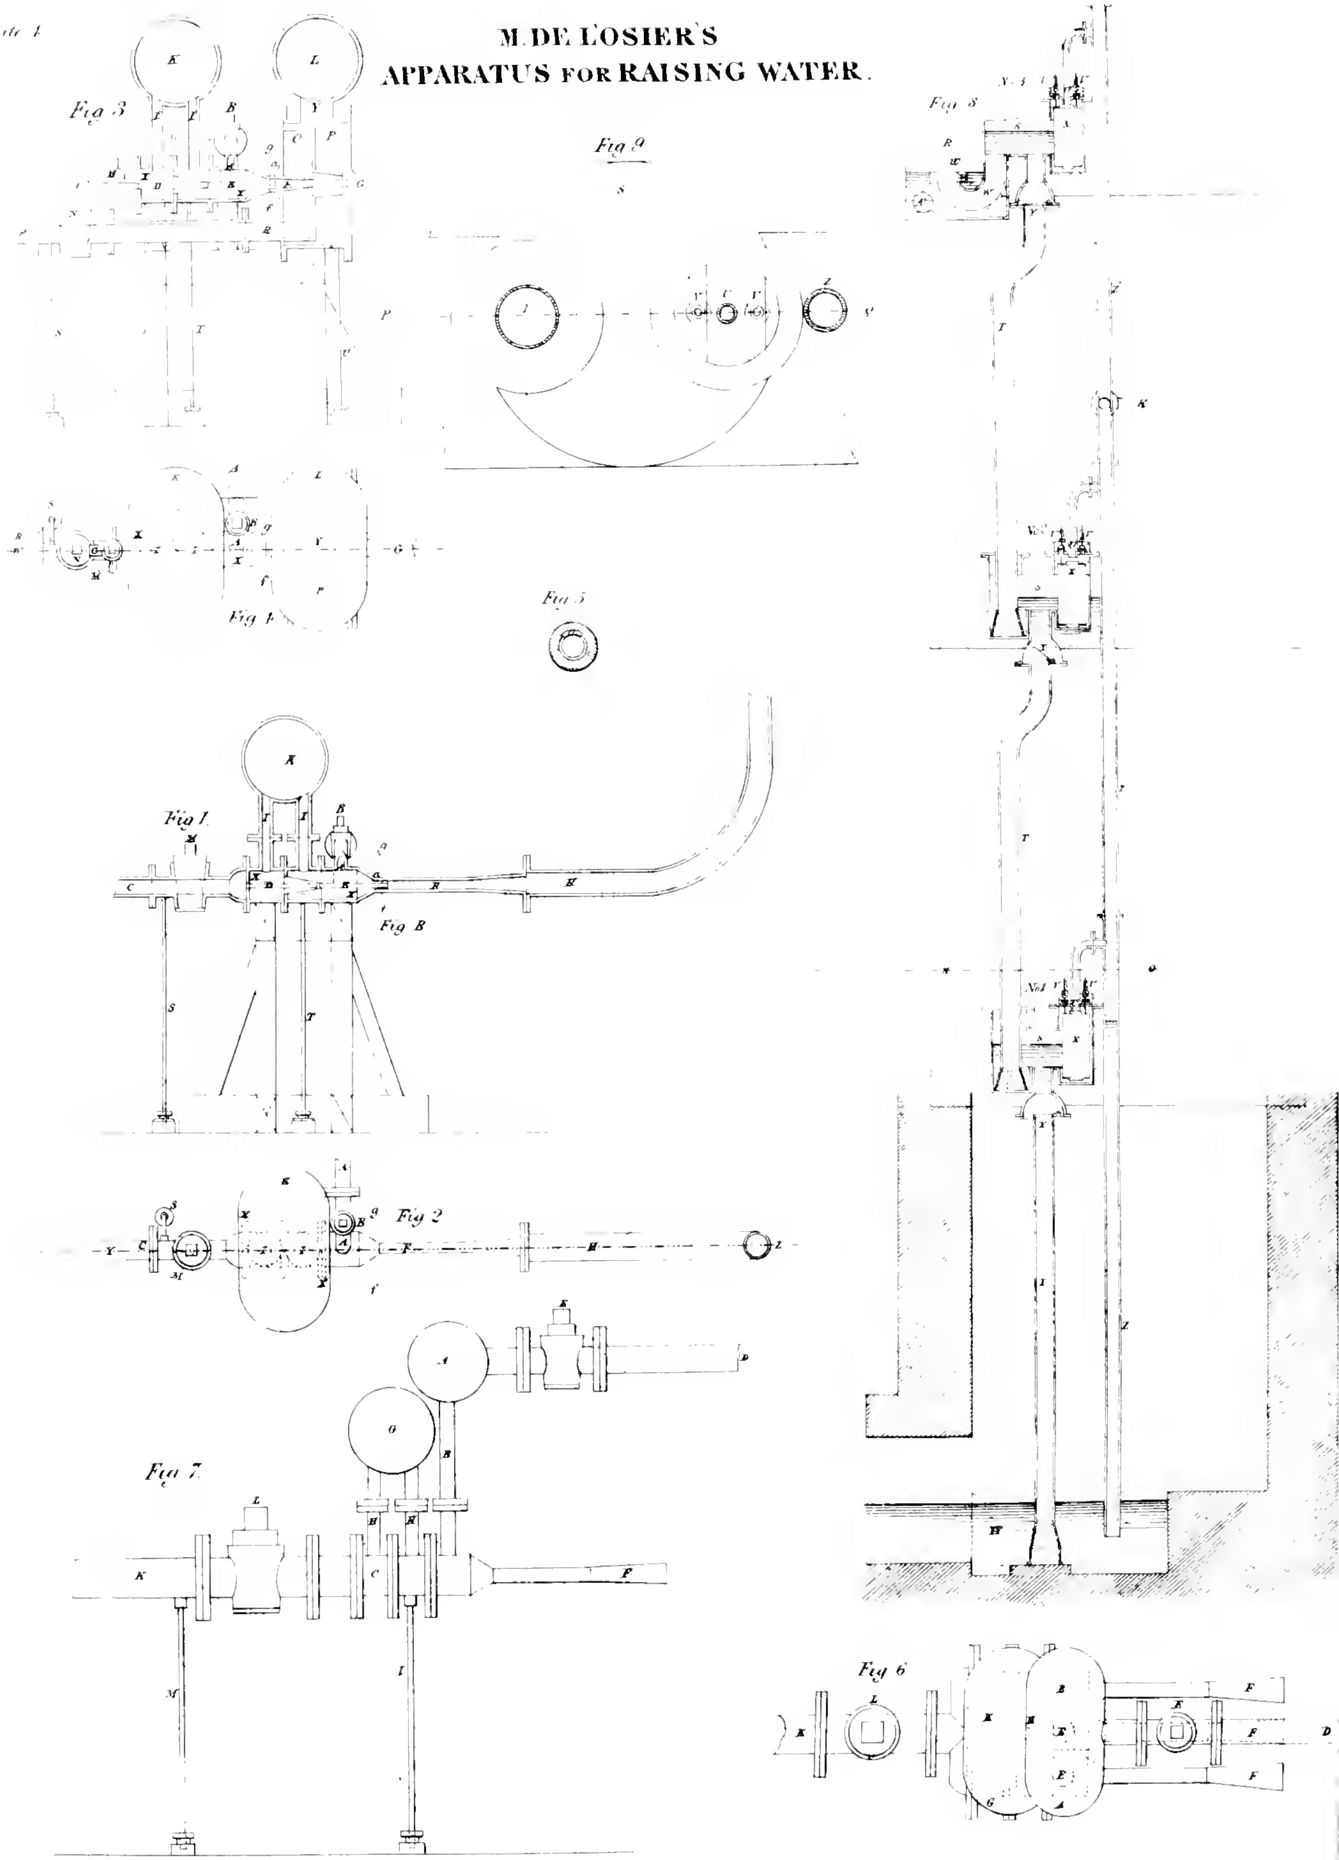
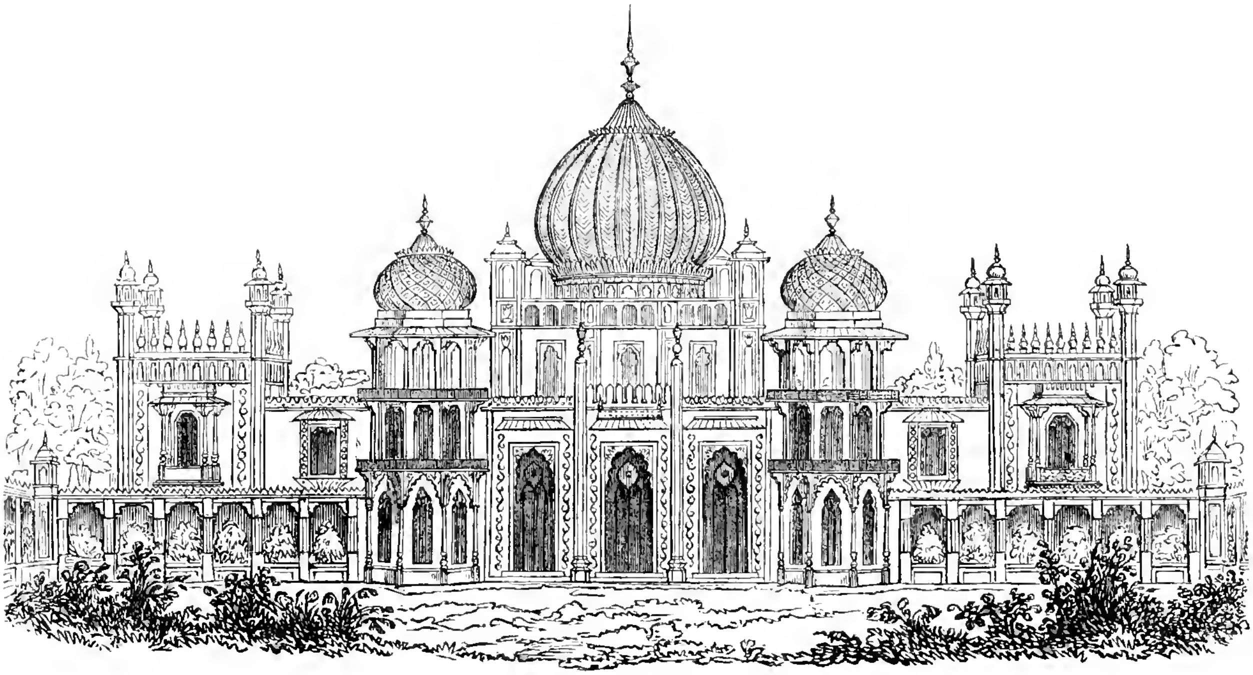
M. DE LOSIER'S APPARATUS FOR RAISING WATER.



J. E. Jobbins Warwick Court

FIG. 3.—WEST FRONT OF THE PAVILION.



Application of Indian Architecture.

"Having already shown the difficulty of adapting either the Grecian or Gothic styles to the character of an English palace, this newly discovered style of architecture seems to present a new expedient for the purpose, in the forms made known to this country by the accurate designs of Mr. Thomas Daniell, and other artists, which have opened new sources of grace and beauty.

"To the materials of wood and stone we have lately added that of cast-iron, unknown in former times, either in Grecian or Gothic architecture, and which is peculiarly adapted to some light parts of the Indian style.

"In Grecian architecture, the artist is confined to five (or, rather, only to three) different orders of columns, so restricted in their relative proportions, that they are seldom used externally, with good effect, in modern houses, and are generally found too bulky for internal use. Indian architecture presents an endless variety of forms and proportions of pillars, from the ponderous supports of the cavern, to the light, airy shafts which enrich their corridors, or support their varandahs. This alone would justify the attempt to adapt a style, untried, for the purpose to which other styles have been found inapplicable or inadequate.

"It is difficult for an artist at once to divest himself of forms he has long studied: this will account for the confusion of Grecian and Gothic in the works of John of Padua, Inigo Jones, and others, about the same date, which occasioned that mixture of style, condemned in after-times for the reasons already assigned. The same thing may be observed in the first introduction of Gothic, mixed with the Saxon and Norman which preceded it: and the same will, doubtless, happen in many instances, during the introductory application of Indian architecture to English uses, while a false taste will both admire and condemn, without any true standard, the various forms of novelty.

"If I might humbly venture to suggest an opinion on the subject, I should recommend the use only of such Indian forms or proportions as bear the least resemblance to those either of the Grecian or Gothic style, with which they are liable to be compared. If the pillars resemble Grecian columns, or if the apertures resemble Gothic arches, they will offend, by seeming to be incorrect specimens of well-known forms, and create a mixed style, as disgusting to the classic observer as the mixture in Queen Elizabeth's Gothic. But if, from the best models of Indian structures, such parts only be selected as cannot be compared with any known style of English buildings, even those whom novelty cannot delight, will have little cause to regret the introduction of new beauties.

"On these grounds, therefore, I do not hesitate to answer the question, concerning which I am commanded to deliver my opinion, that the Indian character having been already introduced (in part) by the large edifice at the Pavilion, the house and every other building, should partake of the same character, unmixed either with Grecian or Gothic; and without strictly copying either the mosques, or the mausoleums, or the serais, or the hill-forts, or the excavations of the east, the most varied and graceful forms should b selected, with such combinations, or even occasional deviations and improvement, as the general character and principles of construction will admit."

Concerning Cobham.

"Whether we consider its extent, its magnificence, or its comfort, there are few places which can vie with Cobham, in Kent, the seat of the Earl of Darnley; and none which I can mention, where so much has been done, both to the house and grounds, under my direction, for so long a series of years; yet, as the general principles in the improvements originated in the good taste of its noble proprietor, they may be referred to, without incurring the imputation of vanity.

"It is now twenty-five years since I first visited Cobham, where a large and splendid palace, of the date of Queen Elizabeth, formed the three sides of a quadrangle, the fourth side being open to the west. The centre building had been altered by Inigo Jones, who had added four pilastres without any attention to the original style, and without extending his improvements to the two long sides of the quadrangle.

"The interior of this mansion, like that of most old houses, however

Fig. 4—Entrance and north front of Cobham Hall, Kent.

adapted to the customs and manners of the times in which they were built, was cold and comfortless, compared with modern houses. A large hall, anciently used as the dining-room, occupied more than half the centre; and the rest belonged to the buttery and offices, in the manner still preserved in old colleges. The two wings contained rooms, inaccessible, but by passing through one to the other; and the two opposite sides were so disjoined by the central hall, that each was entered by a separate porch.

"The great hall at Cobham has been converted into a music-room, of fifty feet by thirty-six, and thirty feet high; and is one of the most splendid and costly in the kingdom. The rest of the central building forms the library, or general living room; which, instead of looking into an entrance-court, as formerly, now looks into a flower-garden, enriched with marble statues and a fountain, forming an appropriate frame, or foreground, to the landscape of the park. The entrance has been removed to the north front, under an archway, or *porte cochère*, over which a walk from the level of the picture gallery (which is up stairs) crosses the road, in the manner described by the annexed sketch, fig. 4, representing the north front, as it has been restored to its original character. In this view is also the bastion, by which the terrace-walk terminates with a view into the park."

We cordially agree with Mr. Repton in the following observations "*Concerning improvements.*"

"I have frequently been asked, whether the improvement of the country, in beauty, has not kept pace with the increase of its wealth; and, perhaps, have feared to deliver my opinion to some who have put the question. I now may speak the truth, without fear of offending, since time has brought about those changes which I long ago expected. The taste of the country has bowed to the shrine which all worship; and the riches of individuals have changed the face of the country.

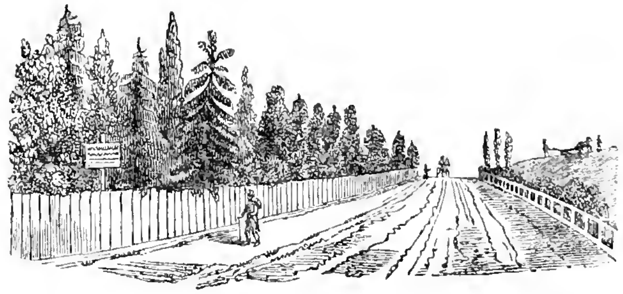
"There are too many who have no idea of improvement, except by increasing the quantity, the quality, or the value of an estate. The beauty of its scenery seldom enters into their thought: and, What will it cost? or, What will it yield? not, How will it look? seems the general object of inquiry in all improvements. Formerly, I can recollect the art being complimented as likely to extend its influence, till all England would become one landscape garden; and it was then the pride of a country gentleman to show the beauties of his place to the public, as at Audley End, Shardeloes, and many other celebrated parks, through which public roads were purposely made to pass, and the views displayed by means of sunk fences. Now, on the contrary, as soon as a purchase of land is made, the first thing is to secure and shut up the whole by a lofty close pale, to cut down every tree that will sell, and plough every inch of land that will pay for so doing. The annexed two sketches, figures 5 and 6, serve to show the effect of such improvement; they both represent the same spot; formerly, the venerable trees marked the property of their ancient proprietor; and the adjoining forest, waste, or common, might, perhaps, produce nothing but beauty; now the trees are gone, the pale is set at the very verge of the statute width of road, the common is enclosed, and the proprietor boasts, not that it produces corn for man, or grass for cattle, but that it produces him rent: thus money supersedes every other consideration.

Fig. 5—View from a public road which passes through a forest waste.

This eager pursuit of gain has, of late, extended from the new proprietor, whose habits have been connected with trade, to the ancient hereditary gentleman, who, condescending to become his own tenant, grazier, and butcher, can have little occasion for the landscape gardener: he gives up beauty for gain, and prospect for the produce of his acres. This is the only improvement to which the thirst for riches aspires; and, while I witness, too often, the alienation of ancient family estates, from waste and extravagance, I frequently see the same effect produced by cupidity and mistaken notions of sordid improvement, rather than enjoyment of property. But, to whatever cause it may be attributed, the change of property into new hands, was never before so frequent; and it is a painful circumstance to the professional improver, to see his favourite plans nipped in the bud, which he fondly hoped would ripen to perfection, and extend their benefits to those friends by whom he is consulted.

"In passing through a distant county, I had observed a part of the road where the scenery was particularly interesting. It consisted of large spreading trees, intermixed with thorns: on one side, a view into Lord * * * * 's park was admitted, by the pale being sunk; and a ladder-stile, placed near an aged beech, tempted me to explore its beauties. On the opposite side, a bench, and an umbrageous part of an adjoining forest, invited me to pause, and make a sketch of the spot. After a lapse of ten years, I was surprised to see the change which had been made. I no longer knew, or recollected, the same place, till an old labourer explained, that, on the death of the late lord, the estate had been sold to a very rich man, who had *improved it*; for, by cutting down the timber, and getting an act to enclose the common, he had doubled all the rents. The old mossy and ivy-covered pale was replaced by a new and lofty close paling; not to confine the deer, but to exclude mankind, and to protect a miserable narrow belt of firs and Lombardy poplars: the bench was gone, the ladder-stile was changed to a caution against man-traps and spring-guns, and a notice that the foot-path was stopped by order of the commissioners. As I read the board, the old man said,—'It is very true, and I am forced to walk a mile further round, every night, after a hard day's work.' This is the common consequence of all enclosures: and, we may ask, to whom are they a benefit?

Fig. 6—View after the forest waste had been enclosed, and the ground subjected to agricultural improvement.



"'Adding to riches an increased store,
And making poorer those already poor.'"

Mr. Repton gives the following interesting testimony to his predecessor Brown, whose example he prided himself in following.

"Mr. Brown's fame as an architect seems to have been eclipsed by his celebrity as a landscape gardener, he being the only professor of one art, while he had many jealous competitors in the other. But when I consider the number of excellent works in architecture designed and executed by him, it becomes an act of justice to his memory to record, that, if he was superior to all in what related to his own peculiar profession, he was inferior to none in what related to the comfort, convenience, taste, and propriety of design, in the several mansions and other buildings which he planned. Having occasionally visited and admired many of them, I was induced to make some inquiries concerning his works *as an architect*, and, with the permission of Mr. Holland, to whom, at his decease, he left his drawings, I insert the following list:—

"For the Earl of Coventry. Croome, house, offices, lodges, church, &c., 1751.
The same. Spring Hill, a new place.
Earl of Donegal. Fisherwick, house, offices, and bridge.
Earl of Exeter. Burleigh, addition to the house, new offices, &c.
Ralph Allen, Esq., near Bath, additional building, 1765.
Lord Viscount Palmerston. Broadland, considerable additions.
Lord Craven. Benham, a new house.
"Robert Drummond, Esq. Cadlands, a new house, offices, farm buildings, &c.
Earl of Bute. Christ Church, a bathing-place.
Paul Methuen, Esq. Corsham, the picture gallery, &c.
Marquis of Stafford. Trentham Hall, considerable alterations.
Earl of Newbury. House, offices, &c., 1762.
Rowland Holt, Esq. Redgrave, large new house, 1765.
Lord Willoughby de Broke. Compton, a new chapel.
Marquis of Bute. Cardiff Castle, large additions.
Earl Harcourt. Nuneham, alterations and new offices.
Lord Clive. Clermont, a large new house.
Earl of Warwick. Warwick Castle, added to the entrance.

Lord Cobham. Stowe, several of the buildings in the gardens.
Lord Clifford. Ugbrooke, a new house.

"To this list Mr. Holland added: 'I cannot be indifferent to the fame and character of so great a genius, and am only afraid lest, in giving the annexed account, I should not do him justice. No man that I ever met with understood so well what was necessary for the habitation of all ranks and degrees of society; no one disposed his offices so well, set his buildings on such good levels, designed such good rooms, or so well provided for the approach, for the drainage, and for the comfort and conveniences of every part of a place he was concerned in. This he did without ever having had one single difference or dispute with any of his employers. He left them pleased, and they remained so as long as he lived; and when he died, his friend, Lord Coventry, for whom he had done so much, raised a monument at Croome to his memory.'

"I will conclude this tribute to the memory of my predecessor, by transcribing the last stanza of his epitaph, written by Mr. Mason, and which records, with more truth than most epitaphs, the private character of this truly great man:—

"'But know that more than genius slumbers here;
Virtues were his which art's best powers transcend:
Come, ye superior train, who these revere,
And weep the christian, husband, father, friend.'"

In these last words Repton has written at the same time his own epitaph, so admirably do they describe him as an artist and a man. At the head of this article is a profile of him, with a diagram illustrative of his doctrine of the theory of vision. He died as he had lived, quietly on the 24th of March, 1818, at Harestreet in Essex, his residence during latter years.

The following extract from his description tells in a few words the man and his character.

"Twenty years have now passed away, and it is possible that life may be extended twenty years longer, but, from my feelings, more probable that it will not reach as many weeks; and, therefore, I may now, perhaps, be writing the last Fragment of my labours. I have lived to see many of my plans beautifully realized, but many more cruelly marred: sometimes by false economy; sometimes by injudicious extravagance. I have also lived to reach that period when the improvement of houses and gardens is more delightful to me than that of parks or forests, landscapes or distant prospects.

"I can now expect to produce little that is new; I have, therefore, endeavoured to collect and arrange the observations of my past life: this has formed the amusement of the last two winters, betwixt intervals of spasm, from a disease incurable, during which time I have called up (by my pencil) the places and scenes of which I was most proud, and marshalled them before me; happy in many pleasing remembrances, which revive the sunshine of my days, though sometimes clouded by the recollection of friends removed, of scenes destroyed, and of promised happiness changed to sadness.

"The most valuable lesson now left me to communicate is this: I am convinced that the delight I have always taken in landscapes and gardens, without any reference to their quantity or appropriation, or without caring whether they were forests or rosaries, or whether they were palaces, villas, or cottages, while I had leave to admire their beauties, and even to direct their improvement, has been the chief source of that large portion of happiness which I have enjoyed through life, and of that resignation to inevitable evils, with which I now look forward to the end of my pains and labours."

The few extracts and illustrations we have given, justify us in saying that the mere collation and condensation of such a mass of materials as are contained in the work before us, would be alone sufficient to confer honour on Mr. Loudon, but his merit is still farther enhanced by the admirable manner n which the whole work has been illustrated and improved.

AN INSTRUMENT FOR ASCERTAINING THE AREA OF IRREGULAR PLOTS.

The Committee on Science and the Arts constituted by the Franklin Institute of the State of Pennsylvania, for the promotion of the Mechanic Arts, to whom was referred for examination an Instrument for ascertaining the area of irregular plots, invented by Thomas Wood, M.D., of Smithfield, Ohio, Report:

That they have examined the instrument invented by Dr. Thomas Wood, and believe it to be novel and ingenious, and very simple in its construction. It consists of two plates of plain ground glass with their inner surfaces fixed in a frame, so as to be parallel to each other, and only so far distant as to permit a piece of drawing paper to slide easily between them. They are of a rectangular form, fastened on three sides in any manner which shall leave the surfaces parallel. The fourth side being open, the space within is partly filled with pure quicksilver. By means of a slip of drawing paper, the outer edge of the quicksilver is made straight and rectangular with the sides. Its position is then marked. This may be done by noting on the paper used, its distance from the outer and open edge of the glasses.

The plot of any irregular plot made from field notes or otherwise, is then moved in till the quicksilver extends to that point of the plot which is nearest the outer and open edge. The outer edge being now parallel to the former edge by the manner in which the paper containing the plot is cut, its distance from its former edge is measured or marked on the same paper, and the area of the irregular field is thus found to be the difference of the areas of two given rectangles.

The committee see no reason why such an instrument should not, when constructed with proper care, give results as accurate as those obtained by the common method of plotting, and dividing into right angled triangles by the dividers and plane scale. The area of the rectangle of any irregular plot, when once completed, may thus be formed in five minutes, and all danger of mistake from errors in the entries or in summing up the partial areas is completely obviated.—*Franklin Journal.*

DEPTH OF THE SEA.

Dr. Patterson read a paper at the American Philosophical Society, by Professor Charles Bonnycastle, of the University of Virginia, containing Notes of Experiments, made August 22d to 25th, 1838, with the view of determining the Depth of the Sea by the Echo.

The apparatus, which is fully described in Mr. Bonnycastle's paper, consisted, first, of a petard or chamber of cast iron, $2\frac{1}{2}$ inches in diameter and $5\frac{1}{4}$ inches long, with suitable arrangements for firing gunpowder in it under water; secondly, of a tin tube, 8 feet long and $1\frac{1}{4}$ inch in diameter, terminated at one end by a conical trumpet-mouth, of which the diameter of the base was 20 inches, and the height of the axis 10 inches; thirdly, of a very sensible instrument for measuring small intervals of time, made by J. Montandon of Washington, and which was capable of indicating the sixtieth part of a second. Besides these, an apparatus for hearing was roughly made on board the vessel, in imitation of that used by Colladon in the Lake of Geneva, and consisted of a stove-pipe, $4\frac{1}{2}$ inches in diameter, closed at one end, and capable of being plunged four feet in the water. The ship's bell was also unhung, and an arrangement made for ringing it under water.

On the 22d of August, the brig left New York, and in the evening the experiments were commenced. In these, Mr. Bonnycastle was assisted by the commander and officers of the vessel, and by Dr. Robert M. Patterson, who had been invited to make one of the party.

In the first experiments, the bell was plunged about a fathom under water and kept ringing, while the operation of the two hearing instruments was tested at the distance of about a quarter of a mile. Both instruments performed less perfectly than was expected; the noise of the waves greatly interfering, in both, with the powers of hearing. In the trumpet-shaped apparatus, the ringing of the metal, from the blow of the waves, was partly guarded against by a wooden casing; but, as it was open at both ends, the oscillation of the water in the tube was found to be a still greater inconvenience, so that the sound of the bell was better heard with the cylindrical tube. At the distance of a quarter of a mile this sound was a sharp tap, about the loudness of that occasioned by striking the back of a penknife again an iron wire: at the distance of a mile the sound was no longer audible.

In the second experiments, the mouth of the cone, in the trumpet apparatus, was closed with a plate of thick tin, and both instruments were protected by a parcelling of old canvas and rope-yarn, at the part in contact with the surface of the water. In these experiments the cone was placed at right angles to the stem, and the mouth directed toward the sound. The distances were measured by the interval elapsed between the observed flash and report of a pistol. At the distance of 1400 feet, the conical instrument was found considerably superior to the cylindrical, and at greater distances the superiority become so decided, that the latter was abandoned in all subsequent experiments. At the distance of 5270 feet, the bell was heard with such distinctness as left no doubt that it could have been heard half a mile further.

The sounds are stated in the paper to have been less intense than those in air, and seemed to be conveyed to less distances. The character of the sound was also wholly changed, and, from other experiments, it appeared that the blow of a watchmaker's hammer against a small bar of iron gave the same sharp tick as a heavy blow against the large ship's bell. It is well known that Franklin heard the sound of two stones struck together under water at half a mile distance; yet two of the boat's crew, who plunged their heads below the water, when at a somewhat less distance from the bell, were unable to hear its sound.

On the 24th of August, the vessel having proceeded to the Gulf Stream, experiments were made with the view for which the voyage was undertaken; that is, to ascertain whether an echo would be returned, through water, from the bottom of the sea. Some difficulties were at first presented in exploding the gun under water, but these were at length overcome. The hearing-tube was ballasted so as to sink vertically in the water. The observers then went, with this instrument, to a distance of about 150 yards from the vessel, and the petard was lowered over the stern, about three fathoms under water, and fired. The sound of the explosion, as heard by Mr. Bonnycastle, was two sharp distinct taps, at an interval of about one-third of a second. Two sounds, with the same interval were also clearly heard on board the brig; but the character of the sounds was different, and each was accompanied by a slight shock. Supposing the second sound to be the echo of the first from the bottom of the sea, the depth should have been about 160 fathoms.

To ascertain the real depth, the sounding was made by the ordinary method, but with a lead of 75 pounds weight, and bottom was distinctly felt at 550 fathoms, or five furlongs. The second sound could not, therefore, have been the echo of the first; and this was proved, on the following day, by repeating the experiment in four fathoms water, when the double sound was heard as before, and with the same interval.

The conclusion from these experiments is, either that an echo cannot be heard from the bottom of the sea, or that some more effectual means of producing it must be employed.

Dr. Hare suggested the expediency of employing the Galvanic fluid to fire gunpowder below the surface of water, in experiments similar to those of Professor Bonnycastle.—*Franklin Journal.*

THE SAFETY LAMP.

At a late meeting of the Geological and Polytechnic Society of the West Riding of Yorkshire, Mr. Charles Morton placed on the table a variety of safety lamps, and proceeded to make some observations and experiments upon them. He called to the recollection of the members the attendance of Mr. Fletcher, of Bromsgrove, at one of the former meetings, when that gentleman produced and described a safety lamp constructed on an improved principle. Mr. Fletcher had since modified his lamp in accordance with the suggestions thrown out at that meeting, and the lamp which Mr. Morton exhibited had been sent to him by the inventor for trial in the coal mines. The novelty of the apparatus consists in a door or damper at the top, which s held up by a string tied fast to the lower part of the lamp. If this string be cut or burnt, the damper drops down and extinguishes the light, in the same way as the shutting of the damper on the top of a furnace chimney puts out the fire beneath. When, therefore, the lamp is introduced into an inflammable atmosphere, the combustion of the fire-damp inside burns the thread, and the damper dropping down destroys the flame. Mr. Morton thought the damper would give rise to so much trouble, that the colliers would not use it. The string is not very readily adjusted, and it passes so near to the wick, that a slight inclination of the lamp, or waving of the flame, burns the string, and the falling of the damper leaves the collier in darkness when he neither expects nor desires such a result; and to get rid of this annoyance he would prop up the damper, and effectually prevent its falling, even when it was desirable that it should do so, *i. e.* when it happened to be in a fiery part of the mine. In other respects, this lamp is much like the one invented by Upton and Roberts. The air for feeding the flame enters through the holes beneath, and is brought into immediate contact with the wick by means of a brass cup. The sides of the lamp are partly glass and partly brass, fitted together so as to prevent the admission of air. In Upton's lamp there is a wire gauze cylinder inside the glass, but in Mr. Fletcher's there is none. By this omission the light produced is much stronger, but the safety is materially lessened; for if the glass of Mr. F.'s lamp were accidentally broken, the naked flame would be exposed to the fire-damp, and an explosion would ensue. Mr. Morton stated that he had submitted this new lamp to a variety of experiments, both in and out of the coal mines, and he considered it deserving the attention of this society. He thought the invention was still capable of considerable improvement, and hoped that Mr. Fletcher (though a gentleman entirely unconnected with mining pursuits,) would devote more of his time and talents to the perfection of an apparatus, the ingenuity of which had already entitled him to the thanks of the public. Mr. Morton remarked that the necessity of attempting to improve the safety lamp would become more generally manifest, if it were universally known that Davy's lamp is *not safe* under certain circumstances. When "the Davy" is introduced into an inflammable atmosphere, *at rest*, it may be said to be safe; but if the lamp be in motion, or if a current of fire damp be directed upon it, there is great danger of explosion. By means of a gas jet on the lecture table, Mr. Morton caused the flame of "the Davy" to pass from the inside to the outside of the wire gauze cage; and he contended that, under similar circumstances, an explosion must inevitably ensue in a fiery coal mine; and he had no doubt some of the dreadful catastrophes that have occurred in the pits were occasioned in this manner. Mr. Morton said that the over zealous admirers of Davy had attributed a quality of infallible safety to an instrument which its illustrious discoverer never ventured to claim for it. On the contrary, this distinguished philosopher, in a treatise which he published more than twenty years ago on the subject of the safety lamp, distinctly points out its *unsafety* when introduced into an inflammable atmosphere in rapid motion; and he warns his readers against using "the Davy" under such circumstances. Mr. Morton was of opinion that if the notion which generally prevails about the absolute and certain safety of "the Davy" were dispelled, it would have a tendency to produce greater care and caution among miners. Mr. Morton, in conclusion, directed attention to an apparatus contrived by Mr. W. S. Ward, of Leeds, which he thought might be used for giving light to fiery mines, or in operations with the diving bell. The apparatus consists of a small gas-holder, containing a compressed mixture of coal gas and oxygen. To this is attached one of Hemming's safety tubes and a common jet, at the point of which is placed a ball of quick lime. The kindled flame of gas being directed upon the lime ball, a brilliant light is produced, and as the light is covered with a glass jar, the flame is rendered safe by being completely insulated or cut off from the external atmosphere.—*Midland Counties Herald.*

Windsor Castle.—About five or six weeks since a fissure was observed in the wall at the north-western extremity of the North Terrace, close to the Winchester Tower, the residence of Sir Jeffrey Wyattville. The opening on the northern side extended from the top of the wall to the surface of the earth on the outer side, a distance of some 20 or 30 feet; and on the western side, from the turrets down to the archway entrance to the vaults beneath, which extend under the whole length of the terrace. As soon as the fissure was discovered, workmen were employed to fill up the interstices (or "point" them) with mortar, in order to ascertain if the cracks would go on increasing. Within a very short period after this had been done, the opening not only widened, but extended along the lower pathway, parallel with the Winchester Tower, to a distance of 14 or 15 yards. The fissure now extends to a distance of upwards of 25 yards. Mr. Whitman, the clerk of the works, upon perceiving the dangerous state of the wall, lost no time in communicating with Sir Jeffrey Wyattville, who was then in London, on the subject, by whom the necessary instructions to proceed in such an emergency were immediately forwarded. Upon entering the vaults underneath the terrace, two large cracks were observable commencing from the bottom of the wall on the north side, extending completely across the arch, and terminating at the commencement of the outer wall of the Castle. These fissures were ordered to be "pointed" in the same manner as those on the outer wall, and with the same results; for after a few days the openings were found to be considerably enlarged. The first step determined upon was to ascertain how far from the foundation of the wall the injury extended, and workmen are now employed in digging a shaft within the arched vaults on the northern side for this purpose. As far as they have yet proceeded, so far extends the opening. It is feared, unless some plan be devised before the breaking up of the frost, to secure the immense mass of stonework which is now in so threatening and dangerous a state, that not only will a large portion of the terrace fall down the steep slope by which it is bounded on the north side, but that it will carry with it some thousands of tons of earth into the vale beneath, where is situated some stabling belonging to the canons of Windsor, and close to which is the extensive brewery of Messrs. Reid and Co., late Mr. Ramsbottom's. Some 12 months ago a deep trench or ditch was dug close to the New Terrace-wall, by order of the dean and canons of Windor, (to whom the slopes and a large piece of land on this side belong), for the purpose of receiving the water which runs off the terrace (after rains, &c.) through small gratings, and which, previously to this being dug, ran down the slopes upon their land below. The trench was intended to have turned the course of this water in another direction; but, instead of doing so, it remained in the ditch, where soaked into the earth, and thus, as it is generally supposed, sapped the very foundation of the wall itself, and thence the dangerous state of this part of the terrace, which was erected as long since as the reign of Charles II., who extended it westward upwards of 100 yards.—*Daily papers.*

Adams's Vertebrated Carriage.—On Monday, 10th December last, a vertebrated carriage, constructed according to the patent plan of Mr. Adams, with bow-spring bearers and buffers, for the Birmingham and Gloucester Railway Company, left the station at Euston Square with one of the trains for Birmingham. Much speculation had existed as to its action on the rails, owing to the various peculiarities of its construction, and especially from the circumstance that all four wheels were loose on the axles, in addition to the axles running as usual in the ordinary bearings. It has been hitherto found that carriages with loose wheels are apt to run off the rails at slight curves, but such proved not to be the case with the vertebrated carriage, which adapted itself to all curves with the greatest facility. In fact, it seemed almost impossible for the wheels to run off the rails, as the axles always disposed themselves at right angles to the line of traction, and the lateral yielding of the springs prevented any friction against the flanges of the wheels. Another objection which had been raised against the carriage, by persons connected with railways, was, that though it might be drawn forwards in a train, it could not be propelled, as the joint would yield, and the wheels go off the rails by an angular thrust. This opinion also proved fallacious, as the carriage was found to go equally well either way. The facility of draught was found far greater than that of carriages on the ordinary plan, though much larger than common, consisting of four bodies instead of three. The facility of its movement was strikingly illustrated at the Euston Station, where two of the wheels got off the turn-table, and escaped from the rails. The usual course in such cases is to raise a common carriage by means of screw-jacks, but owing to the action of the joint, and the free movement of the wheels, the vertebrated carriage was rolled upwards by the labourers with little apparent difficulty, without resorting to mechanical aid. We understand that it is intended to run the carriage between London and Birmingham, previous to the opening of the Gloucester Railway, and judging from its satisfactory performance in remedying various railway evils, there seems to be little doubt that this plan of carriage will come into general use. We understand that another improvement by Mr. Adams will shortly be brought forward, consisting of a more perfect lubrication of the axles by means of oil instead of grease, and without the usual waste, so that a carriage will probably run a week with only once oiling. We apprehend that the saving of friction on the wheels, owing to the free revolution independent of each other, will materially increase their durability.—*Railway Times.*

COLLEGE FOR CIVIL ENGINEERS.

In the year 1838, our attention was aroused to a correspondence which had crept into the Times and Athenæum, attempting to lower the character of the profession in this country, and to set up a foreign standard. We rightly surmised that this was a coming event, which cast its shadow before it, that it was the wish father to the thought, which was to usher in some expedient to correct the assumed abuse, and introduce the new doctrine. Accordingly we hastened to attack the new-born hydra, and on repeated occasions expressed our sentiments relative to their new school of error. Remarks upon this subject will be found in volume the first, page 369, and volume the second, pages 13, 86, 124, 152, and 351. On account of this solicitude for the interests of the profession, we were assailed in a violent manner by the advocates of the projected College; what they gained by the attack our readers know.* In the meanwhile, the plan has been brought to light, a scheme of operations organised, and active preparations made for carrying them into effect. While the intentions of its managers were not publicly declared, and while they had yet the opportunity of adopting a sane course, and according to the wishes of the profession, we left them to carry on their designs in peace. Now that the mask has been lifted—now that war has been delared against the whole profession, and that an open attempt is made to poison the public mind with error, we feel it our bounden duty to call the serious attention of our readers to the mischievous and fallacious objects, which it proposes to effect. In this investigation, we shall enquire, first, as to the mode of education required by the profession; secondly, as to how far this is supplied; next, as to the merits of the proposed plan; fourthly, how it has hitherto succeeded, and what are its future prospects; and lastly, how far it might be rendered useful.

We have, on previous occasions, already defined engineering,† as a profession requiring two distinct faculties, the theoretical and practical, the inventive and the constructive. This is a view sanctioned by the highest authorities. The Report of the Institution of Civil Engineers for 1837,‡ describes the engineer as a mediator between the philosopher and the working mechanic. In their Report for 1838,§ they say, "The objects of the Civil Engineer are defined by your charter, and the council considering that the success and permanency of the Institution must depend, in a great measure, on the care exercised in admission into this class, have repeatedly considered this subject with the view of presenting some definite rules for the guidance of themselves and others. It has appeared that they will be aided in this difficult task by adhering as much as possible to the two following conditions; either:—"

"He shall have been regularly educated as a civil engineer, according to the usual routine of pupilage, and have had subsequent employment for at least five years in responsible situations as resident or otherwise in some of the branches defined by the charter as constituting the profession of a civil engineer; or, he shall have practised on his own account in the profession of a civil engineer for five years, and have acquired considerable eminence therein."

"It is thought that the first condition will include those who by regular education have done their utmost towards themselves for the profession, and that their subsequent employment in responsible situations will be a guarantee that they have availed themselves of the opportunities which they may have enjoyed."

"In the earlier days of the science of the civil engineer, such a condition would have been inapplicable; then the force of native genius sufficed to place the individual in that position of professional eminence which commenced with a Brindley and a Smeaton, and was in our own time exemplified in a Rennie and a Telford. To such, of whom there are many illustrious examples amongst us, the second condition is strictly applicable."

The profession, particularly in its present infant state, is ever called upon to provide for unexpected contingencies, to make new precedents, and supersede old processes. The last ten years has seen a new and important branch created, and scarcely established, before it found itself, by new improvements, obliged to abandon all its former calculations, and follow new models. The profession, therefore, is well defined as of two classes, and as uniting two branches of instruction. The accessory portion of instruction is one common to most practical pursuits, and a part of higher education at the same time, consisting as it does, of the mathematical and physical studies, it needs no excathedral inculcation, but admits of being attained by private study by those engaged in the practical department. Like literature, like the arts, it necessarily follows, that its greatest names are not recruited from apprentices to the system, but from every class of society, it admits the collegian and the mechanic; every man, who feels himself called upon by the divine voice to a destined pursuit. Who have been our greatest engineers? not students from a college, or an apprenticeship, but the stone mason and the blacksmith, the labourer and the millwright. Engineering is not like law, bound up in an endless mass of precedents, admitting few new cases, and fearful of diverging from established rules, but it is ever new, ever changing, ever supplanting the past, by anticipations of the future. It does not, like medicine, require the study of a complicated and little known machine, nor a special application of many difficult sciences to its own objects, it does not require mere judgment to apply old rules, but it perpetually encounters new cases, and applies new remedies. The records of its operations are hardly published when they become useless and superannuated; many branches are hardly sufficiently advanced to have any literature at all; consequently, for those seeking practical instruction, the workshop and the field are the only schools; the house cannot be judged by a brick, the sea cannot be measured by a bowl of water, nor can the operations of the engineer be taught on any other scale of truth than on that of the works themselves. The lawyer and the surgeon find no college allsufficient for their instruction, they find not even the court house or the hospital alone efficient, but under the care of the acting practitioner, they are obliged to seek the basis of their education. It is remarkable indeed that a departure should be attempted in this sound course, when other professions are even carrying it to a greater extent; so distrustful are the medical authorities of oral instruction, that they now require at their examinations practical dissections and manipulations.

Engineers may be classified under the following heads:—

1. Civil Engineers—Roads and Railways.‖
   Canals.
   Bridges.
2. Mining Engineers—Mines.¶ Draining.
3. Marine Engineers**—Ship Building.
   Harbours.
   Docks.
   Light-houses.
   Dykes.
4. Military Engineers.
5. Practical Engineers—Land Engines.
   Locomotive Engines.
   Marine Engines.
   Manufacturing Engines.

Subsidiary to these are Surveyors, Working Engineers, Locomotive Engineers, and Steam Vessel Engineers. The instruction required for these classes, we consider to be a practical acquaintance with the details of the technical portions, to be acquired under the guidance of practical men in actual operations, and a study of the accessory sciences connected with their pursuits. Ample instruction in the former department is to be obtained from the existing engineers; and with regard to supplementary education, numerous institutions exist, independently of the amount of knowledge communicated by mechanic's institutions and other sources. The Institution of Civil Engineers, and the Universities of London and Durham, and the Military Colleges grant degrees, and classes are formed in London at University and King's College, in those of Norwich, Chatham, Sandhurst, and Addiscombe, and Hanwell Collegiate School; in the Provinces, in the Colleges of Durham and Bath, the Cornish Mining School, the Scotch Naval and Military Academy, at Edinburgh, the Royal Dublin Society's School, at Dublin, the Agricultural School, at Templemoyle, King William College, Isle of Man, and Elizabeth College, Guernsey. The elements of surveying are taught in many of the schools for the middle classes.

We have now to consider the proposed plan of the College for Civil Engineers, which assuming different principles, calculates upon supplanting the existing modes of instruction. These are given to the public in a pamphlet, the confusion and ridiculousness of which, for the present, we pass by unquestioned and unremarked. This prospectus boldly asserts, that with regard to the demand for efficient practitioners in civil engineering, not one of our Universities or public seminaries has kept pace with this want of the age, and afforded a suitable education for the aspirants in that new profession;—the best answer to this is to be seen above. What they mean by the following, they themselves can best explain. "They are, in a

§ Vol. ii. p. 73.

‖ Ingenieurs des Ponts et Chausees, French.
¶ Ingenieurs des Mines, French.
** Ingenieurs des Travaux Maritimes, French. Water Staat, Dutch.

great measure, responsible for the profits on our internal industry—on the average of which depend agricultural returns, and also by re-action, an increased demand for labour." The fundamental basis of operations is that the whole instruction, both theoretical and practical, shall be given in the College. This, according to the account of its managers, includes the structure of railways, roads, canals, docks, locks, and harbours, improvement of rivers, clearing mines of water, and their necessary ventilation; the whole structure of the steam engine, land and water transport, architecture and general construction, naval architecture, mining, drainage, embanking, reservoirs, light-houses, arsenals, surveying, levelling, mineral boring, modelling, casting and forging, turning and boring. And what is to feed this multitude?—two loaves and five small fishes—a few professors of mathematics, drawing and latin, an architect, and some acres of ground at Hampstead!!! Is there any one so insane as to attempt to carry out such a scheme?—is there any parent so wasteful of his own money, or regardless of the interests of his child as to entrust him to such a school? In an arena, scarcely fit for a cricket match, are we to see exemplified the wonders of British art; here, by magic processes, are to be reproduced *ad infinitum* the Grand Trunk Canal, the Eddystone Light-house, the Steam Engine, the Menai and Waterloo Bridges, and Birmingham Railway, with its vallied cuttings, its Kilsby tunnels, and its hilly embankments. The Clifton Bridge would span the ground, the Camden Town Embankment, swallow up the soil, and the cutting to Euston Square take in the whole estate. "Philosophy in sport, made science in earnest." We are either to believe these delusions, or we must recognise the sad reality, children mis-spending their father's money and their own time on mimic railways, and gutter canals; expert in all the verbiage which a well disciplined memory can retain, and going out into the world the children which they came into the college. If this be the offspring of the Polytechnic School, an Institution which has flourished under some of the noblest men in France, we believe that, with indignation, they will disavow their bantling; if it be an imitation of Russia, it is an imitation rather of the barbarism, than of the grandeur of that nation; we know that no example in favor of it exists in any other country. In the workshops, South Wales, Birmingham, Glasgow and Newcastle are to be united; the steam engine is to be wrought, by boys, from the native ore into all its wonderful applications as a motive power. What more they profess to teach we know not, we know that all these things, even if practicable as toys, will fail to make engineers such as England has and England wants. The ignorance of the projectors is only equalled by their absurdity; the manner in which the design is to be carried out, is expressed by a synopsis of the course of instruction extending over a peaiod of five years, in the first two years of which the pupils learn nothing of engineering, except surveying and levelling, their principal acquirement being caligraphy; in the second year we find these branches are taught in conjunction with mineral boring and draining, and the principles of Civil and Naval architecture. No progress has yet been made in engineering but never mind, we can wait. The third year advances to shaded and coloured drawing, drainage, embanking, and conduct of running water, and the construction of roads; leaving, consequently, the whole instruction for the last two years. In this course, we find that the principal engineering works (*i. e.* treatises) of the English, French, and Germans are to be read. What those French and German works are we should very much like to know;—to the best of our knowledge very few works exist, except translations from the English. Among the *magna opera* of the last year, we find such terms as "a grand drawing, with plans, sections, and parts in detail;" "grand project for internal transport by land or water, with estimates;" "a memoir on some important question of civil engineering." The pennyworth of bread to these gallons of sack, is the examination and explanation of public works on the works themselves. The "lucidus ordo" of the synopsis must be evident to the most unsystematical; drawing and caligraphy interpolated between mechanics and hydrography; architecture between hydrography and physics, and the same impartial system is carried throughout. As to the workman's class, for which twelve guineas a year is to be charged, the paltriness and inadequacy of instruction given exempts it from notice. The pupils may be admitted into the high school at fourteen years, and on going through the prescribed course of instruction, as any youth of moderate abilities and sufficient memory is sure to do, is turned out on reaching his eighteenth birth-day, a duly qualified successor of Brindley, Smeaton, Rennie, Telford, and Watt.

This system, we may observe, is a clumsy imitation of the Polytechnic School, and other similar Institutions abroad, which are adopted in the imperfect state of instruction, to supply the want of a more practical course. In the Polytechnic or Gwerbe School, the student finds those models which he can find with difficulty elsewhere, but under the guidance of a Stephenson or a Maudsley, he learns in that school, which is the model to all Europe. In our pages* will be found an account of the state of engineering abroad. What it is here all Europe tells; we boast the names of Middleton, Worcester, Hooke, Savery, Newcome, Brindley, Milne, Smeaton, Bell, Edwards, Arkwright, Rennie, Macadam, Bramah, Huddart, Trevithick, Telford, Woolf, and Murdoch; and among the engineers of the present day:—Walker, Stephenson, the two Rennies, the two Brunels, Cubitt, Locke, Maudsley, Tierney Clarke, &c., many of whom enjoy an European reputation. Such are the fruits of a defective system: what has Europe to show against it? The same defective system prevails in the United States, where gigantic works of the engineers measure the continent from one end to the other.

As to what must be the result of the proposed system, we fear we can augur nothing very good, on one side they are deficient in strength, and on the other side they have to compete with powerful rivals. The plan of the College itself, and its details, have been rendered ridiculous by fantastic absurdities; the very first page of their prospectus is calculated to excite laughter;—a College for Civil Engineers, plastered with the names of a set of Eton schoolmasters, as honorary members; unknown foreigners, as corresponding members; the prospectus is dashed throughout with unmeaning italics; the distinguishing absurdities of the Hone and Black Dwarf School; the vice of those, who wanting strength of thought, make it up by variety of type. One of the professorships is to be held by a clergyman of the church of England, another is the chaplain, and sectarianism is openly proclaimed in a building devoted to the national pursuit of science. Of what religion were the Marquis of Worcester and Watt? "The College is based upon the principles of the established Church." Church of England railways, Catholic steam engines, and Presbyterian canals, whoever heard of such things? Could not the moral and religious instruction of the students be provided for without injuring the feelings of large masses of the population, by giving a preference to a minority? The food of the boarders will be of the best description, and every care taken of their health!—shades of Brindley, Arkwright and Rennie, whoever heard of such superfluous nonsense! "No pupil can be admitted without a certificate that he has had the small pox, or has been vaccinated; and has no particular infirmity or contagious malady." "He must be able to read! and write! fluently, and be master of the first four rules of arithmetic!!" "Corporal punishment will not be permitted in the establishment!"—"Suppose a gentleman designs one of his sons, at the age of five years!!! to be a civil engineer."

As to the supporters of this College, we find many men of high title, but we look in vain for the support of any of the great men, who, by their engineering works, have contributed to their country's glory. Only three names are to be found qualified as engineers, none of whom are sufficient to attract of themselves public support. As to the professors, of whom, by the bye, there are none for engineering, it is saying enough for them to mention, that many of the names are respectable.

We now come to another question of the deepest interest to those parents, who are so ill advised as to send their children to this rickety College, that is, what is to become of the lads when they have got their diplomas? Will they be employed by the present engineers in preference to their own pupils?—will they have greater weight with the public, than men of acknowledged eminence?—will they be supported by the public like those who have received a practical education under first-rate men? Our impression is, that they will not, but that the lads will, after their five years of College education, and an expenditure of several hundred pounds, be obliged to pitch their diplomas into the Thames, and article themselves to those who know something of the profession. We earnestly call on all who may be tempted by the luring proposals of destining children from the cradle, and hatching engineers with more than an Eccaleobion power, to pause and reflect on the waste of time and money which they must incur from any failure of this kind, and to hesitate before they become the victims of a few deluded theorists. So sanguine are the projectors, that they talk of entrapping hundreds of lads, and think nothing of a hundred engineers as the average produce of a year. This, according to our reckoning, would of itself produce three thousand engineers, besides those educated in other establishments;† and what is to become of the raw and ignorant

* Vol. i. p. 369.

† As to how they are to support the competition of the engineers and existing colleges, its managers may know better than we pretend to do. They will be able to solve whether Everett, Webster, Wallace, and Elmes are equal to De Moran, Silvester, Lardner, and Graham, or to Hall, Moseley, Daniell, Wheatstone, Phillips, Bradley, Cooper, and Tennent.

youths?—those best will be able to decide, who can coolly give utterance to such preposterous delusions.

As to the manner in which they are supported by the profession, it may perhaps be sufficient to refer to the men connected with it, but we have farther public testimonials in the declarations of the Institution of Civil Engineers. The liberality of their opinions we have already shown, so that anything emanating from them, carries with it the whole weight of their character, and is free from the imputation of interested motives. Their Report for 1837,* while advocating the necessity of supplementary instruction, states that much has at times been said respecting the establishment of a School of Engineers, and many comparisons have been drawn betwixt the advantages possessed by this and other countries in this respect, but not for an instant to enter on the great question of the nature of a complete establishment under that name, it may with confidence be asserted, that this Institution is in itself a School of Engineers—a school not in the sense of the term where knowledge is forced upon the unwilling student, but one where the attentive student possesses remarkable opportunities of self-improvement by study and mutual intercourse. In the speech of the President, on opening the Session of 1839,† he calls upon the members to improve themselves, not by collegiate instruction, but by mutual improvement; he says, "there is now upon the table, a prospectus for the establishment, on a large scale, of a College for Civil Engineers," leaving his hearers to form their own opinions upon the merits of such proposition.

That there is room for the establishment of a school of engineering on sound principles, it admits no question; but its sphere, although extensive, is very different from that contemplated by the present plan. Its advocates jump at once to conclusions, inspired by the ardent hope of obtaining large premiums, they jumble everthing together, and mix up the practicable with the impracticable. Stephenson or Brunel carry on no trade in premiums of five hundred guineas, it would make little diminution in their incomes, if they had no pupils at all, but young men are sent to them because from their employment in large works, they have great facilities in affording instruction, and ample means of employing them afterwards. If the council of the College want to know what to do with their establishment, we can tell them how it may be made useful to the public, and profitable to themselves and their pupils. Let them require that every pupil in civil mining, marine or practical engineering shall be articled to a practitioner, and let them like University, King's, and Durham Colleges, limit themselves to teaching the theoretical branches. Form a special class for instructing steam vessel engineers, and they may claim a government grant and a class for locomotive enpineers, and railway companies would probably contribute. Educate surveyors, and instruct them in the higher branches of geodesiacal operations, not as planned by the College, merely the rudiments of astronomy, but its application in trigonometrical surveying. Give supplementary education to mining engineers, and train up mineralogists and assayists. Teach like King's College, the literature of manufactures and machinery, but let the pupils study in the factory instead of the toy-shop. Do the same for the manufacturing chemist, London has establishments enough for his practice. Let the Universities or the Institution give the diploma, and limit the College to teaching, and still will be done more than enough for a beginning, and what will amply pay for all expenses.

In concluding these remarks, we cannot too strongly repeat, that parents should hesitate before they compromise the interests of their children, by sending them to this establishment, and we call on its managers to pause in their career, before they have yet excited the open hostility of the profession, and to devote their energies to a useful and rational purpose, before they are crushed by a powerful opposition. We have been influenced by no prejudice against the College or its objects, but we feel that we have best done our duty both to it and our readers, by unsparingly denouncing what we consider an erroneous and inefficient system of education, and a certain delusion to those who have the misfortune to be its victims.

† See Vol. ii. p. 3.

Oxford University.—Few persons are aware that 100,000*l.* was left to the University of Oxford by Michael Angelo Taylor, to build a picture gallery and lecture rooms connected with science and arts. A dispute having arisen between his relatives and the trustees respecting the will, the latter, rather than risk a suit in Chancery, have agreed to take 75,000*l.*, and have begun clearing the foundation for the building. They have removed the old houses at the corner of Beaumont-street, St. Giles's, nearly opposite St. John's college, which is the most central they could meet with.

GENERAL THEORY OF THE STEAM ENGINE.

By Aristides A. Mornay, Esq.

No. V.

On the Action of the Steam in the Cylinder (continued.)

In our last number we demonstrated that the pressure exerted by the steam against the piston may be assumed in practice as equal to its full elastic force; we intend in a future paper to enter into an investigation of the elastic force of the steam at different instants during the stroke of the piston, preparatory to which it will be necessary to inquire into the effects of an arrangement, which exercises a material influence on the elastic force of the steam during a portion of the stroke of the piston when it is adopted: we allude to the *lead of the slide*, which is considered indispensable in Locomotive Engines.

The *lead* is the advance given to the motion of the slide, by which it is caused to shut the eduction port, and open the steam port a little before the commencement of the stroke, and to shut the steam port and open the eduction port a little before the end of the stroke.

In order to explain the reasons assigned for giving a lead to the slide in locomotive engines, we think we cannot do better than quote the following from the description of Stephenson's Patent Locomotive Engine, in Weale's splendid edition of "Tredgold, on the Steam Engine," pages 450 and 451 of the Appendix. "It is found necessary to let the steam on to the opposite side of the piston before the end of the stroke, in order to bring it up gradually to a stop, and diminish the violent jerk that is caused by its motion being changed so very rapidly as five times in a second. The steam, let into the end of the cylinder, before the piston arrives at it, acts as a spring cushion to assist in changing its motion, and if it were not applied, the piston could not be kept tight upon the piston rod. A little lead of the slide is also necessary that the steam may be admitted through the port into the cylinder, and be completely ready to begin the next stroke when the piston is at the end of the cylinder; but so much is not necessary for this.

"The principal advantage gained by giving lead to the slide is in beginning to get rid of the waste steam before the commencement of the stroke; so that when the piston commences its stroke there is but little waste steam before it to resist its progress, the steam beginning to be let out of the cylinder before it has driven the piston to the end of the stroke. This is a very important point in a locomotive, as the resistance or negative pressure of the waste steam upon the piston is very considerable; from the rapidity of the motion, which allows very little time for it to escape, and from the use of the blast pipe, which obstructs its passage. The area of the extremity of the blast pipe is only five square inches, while that of the steam port is eight square inches, requiring the velocity of the steam in the blast pipe to be considerably greater than in the cylinder. The average negative pressure of the waste steam throughout the stroke is 6 lbs. per square inch when running at the usual rate of 25 to 28 miles an hour; and at greater velocities the negative pressure has been found to increase to double that amount and even more."

From the first reason the evil it is intended to remedy by the lead of the slide appears to be, the tendency of the piston to become loose on the piston rod, through the violent jerks caused by the motion of the piston being changed so very frequently as 5 times in a second. We have to ascertain first, the immediate cause of the jerks, secondly, the manner in which they occasion the piston to work loose, thirdly, their force, and lastly, in what manner and to what extent this is diminished by the lead of the slide.

In order to account for the production of these shocks or jerks, we will consider what passes in the cylinder of a locomotive engine, and first on the supposition that the steam acts on the piston with its full pressure to the very end of the stroke, and that it is then shut off and immediately begins to press with its full force on the other side of the piston.

On this head it is necessary to observe that, under the circumstances here assumed, the steam could not, at the instant the piston commences the stroke, press upon it with its full force (that is, with the same force as in the middle of the stroke), on account of the necessity of first filling the steam passage and waste space at the end of the cylinder. But, since the pressure of the steam remaining in these waste spaces does not sensibly exceed that of the atmosphere, while the fresh steam admitted into them has a very great excess of pressure, say 50 pounds on the square inch, the time required to fill them is certainly very much less than that required to fill one hundredth part of the contents of the cylinder, during which time the steam is pressing upon the surface of the piston with a force increasing from the atmospheric pressure to the maximum pressure attained during the stroke. With respect to the gradual opening of the port, that would not of itself affect the pressure of the steam in the cylinder in any degree, since the degree of opening is constantly proportional to the velocity of the piston, by which means the supply of steam is always equal to the demand. This is equally true while the steam-port is being closed in the last half of the stroke. We may therefore be permitted to assume, as above, that the steam presses on the piston with its full force during the whole time that the steam-port is open.

We may also, for the sake of simplicity, assume the motion of the crank to be strictly uniform; for the variations of power are so exceedingly slight in comparison with the energy of the moving mass, on account of the arrangement of the two cranks, that no sensible variations in the velocity of the engine can possibly result therefrom.

Under these circumstances, when the piston has just arrived at the middle of the back stroke, its motion may be regarded for an instant as uniform, since it is changing from an accelerated to a retarded motion: the strain on the key which connects the piston to the piston-rod is therefore equal to the effective pressure of the steam on the piston *minus* the friction of the latter against the surface of the cylinder. But as soon as the piston has passed the middle of its stroke, its motion begins to be retarded, and since the retarding force has to be transmitted from the piston-rod to the piston through the medium of the key which connects them, the latter has to bear the strain of this force in addition to the pressure of the steam on the piston, which it had to bear in the middle of the stroke. This retarding force must evidently increase from the middle to the end of the stroke with the rate of retardation of the piston's motion. The strain at the end of the stroke will therefore be equal to the effective pressure of the steam on the surface of the piston, *minus* its friction, *plus* the greatest retarding force, since the retardation is then the most rapid. At the commencement of the fore stroke, the pressure of the steam is equal on both sides of the piston, and there is consequently no power to move the piston but such a portion of the momentum of the engine as is sufficient to overcome the inertia and friction of the piston. The former requires a force precisely equal to the retarding force at the end of the stroke, so that the strain is suddenly diminished by the effective pressure of steam on the piston *minus* twice its friction; and the remaining strain is gradually, though quickly, taken off by the escape of the waste steam allowing the steam on the other side of the piston to exert sufficient force to accelerate its motion. From the moment when this is the case all the pressure is borne by the conical end of the piston-rod, until it arrives at the corresponding point of the back stroke, from which the strain on the key increases gradually until it attains its maximum at the end of the stroke, as we have already explained.

In locomotive engines, where the steam is used at very high pressures and the pistons are light, the strain due to the retardation of the motion of the piston is very inconsiderable in comparison with that due to the pressure of the steam, as we shall presently prove, when we calculate the intensity of the retarding force: so that comparatively very little increase of strain takes place during the last half of the stroke, this increase being due to the retardation of the piston alone, while the increase during the first half amounts, as we have already mentioned, to the whole effective pressure of the steam: for by the time the piston has passed through the first half of the stroke, the pressure of the waste steam must be reduced very nearly to that of the atmosphere.

The shocks complained of appear therefore to be due, not to the inertia of the piston requiring a considerable force to change its direction, but to the alternate action of the steam on the two sides of the piston producing a strain on one side of the key which reaches its maximum at some point of the *back* stroke, and is taken off entirely during the *fore* stroke.

The mode in which this intermittent strain on the key may cause it to work loose is evidently by the alternate compression and relaxation of its substance; but the effect of this might be prevented by securing the key with a screw in the same manner as the key at the crank end of the connecting rod.

We have said that the chief part of the strain on the key of the piston is due to the pressure of the steam; this investigation would however be incomplete without a calculation of the strain due to the inertia of the piston in consequence of the great variations in its velocity. This strain is evidently equal to the force which would be required to produce a certain acceleration or retardation in the motion of the piston, and an accelerating or retarding force is proportional to the rate of acceleration or retardation which it produces.

Let V = the mean velocity of the piston in feet per minute, l = the length of its stroke, v = its velocity at any given instant, λ = its distance from the end of the stroke, α = the angle contained between the crank and the direction of the stroke, and x = the rate of retardation per minute, at the given instant.

Supposing, for the sake of simplicity, that the motion of the crank is strictly uniform (which is very nearly true in reality), and that the connecting rod is infinitely long in comparison with the crank, the circumferential velocity of the crank pin will be $\frac{\pi V}{2}$, and we shall have

$$v = \frac{\pi V}{2} \sin. \alpha,$$

whence we obtain by differentiation

$$d v = \frac{\pi V}{2} \cos \alpha \, d \alpha.$$

The actual distance to be passed through by the crank pin before it arrives at the dead centre is $\frac{l}{2}\alpha$, which divided by its velocity $\frac{\pi V}{2}$, gives for the time required to travel that distance

$$t = \frac{l \alpha}{\pi V},$$

whence

$$d \alpha = \frac{\pi V}{l} d t.$$

Substituting this expression in the value of $d v$, and dividing by $d t$, we obtain

$$\frac{d v}{d t} = \frac{\pi^2 V^2 \cos \alpha}{2 l} = \frac{\pi^2 V^2 (l - 2 \lambda)}{2 l^2}.$$

And since this quantity expresses the retardation of the piston per minute, we have also

$$x = \frac{\pi^2 V^2 (l - 2 \lambda)}{2 l^2}.$$

The retardation per minute produced by the force of gravity is about 115,884 feet, which if we call G, we shall have

$$\frac{x}{G} = \frac{\pi^2 V^2 (l - 2 \lambda)}{231768 \, l^2}.$$

If then we call w the weight of the piston, and W the pressure due to the retardation x, we shall evidently have

$$\frac{W}{w} = \frac{x}{G} = \frac{\pi^2 V^2 (l - 2 \lambda)}{231768 \, l^2},$$

or the strain on the key of the piston is equal to the weight of the piston multiplied by the quantity $\frac{\pi^2 V^2 (l - 2 \lambda)}{231768 \, l^2}$.

As an example let $V = 500$, $l = 1{\cdot}5$, and $\lambda = \frac{1}{48}$. Supposing the driving wheels of the engine to be 5 feet in diameter, the speed under these circumstances would be 29·75 miles per hour. The strain W on the key of the piston is required, when the latter has arrived at a quarter of an inch from the end of the stroke, which is the lead usually given to the slide in locomotives. By the preceding equation we have

$$W = w \frac{3{\cdot}1416^2 \times 500^2 \times \frac{35}{24}}{231768 \times 1{\cdot}5^2} = 6{\cdot}9 \, w.$$

On inspecting the general equation given above, it will be evident that, all other circumstances remaining the same, the value of W varies as the square of the velocity of the piston, and that it increases as the piston approaches the end of the stroke, the strain at the very end being equal to the weight of the piston multiplied by the quantity $\frac{\pi^2 V^2}{231768 \, l^2}$. Under the circumstances assumed in the above example we should therefore have at the end of the stroke

$$W = 7 \, w.$$

It likewise appears that, with various lengths of stroke but the same velocity, the strain is inversely as the length of the stroke, when the piston is at proportionate distances from the end.

The same calculation applies, of course, as well to the first as to the second half of the stroke of the piston, and is improperly omitted in the consideration of the unequal action of the steam on the crank and the effect of fly-wheels; but in these calculations it is not only the weight of the piston, but that of all the alternating parts of the engine, that must be taken into account. In the same manner the strain on the key which connects the piston-rod with the cross head is a multiple of the weight of the piston and piston-rod, and so on for the other joints. It is, however, necessary to deduct first in each case the friction on the piston and other parts which may intervene between it and the joint under consideration.

Since the strain calculated by the preceding method is due simply to the inertia of the piston, it is clear that, in order to find the whole strain, it will be necessary to increase the former by as much as the pressure of the steam against the surface of the piston may exceed that of the waste steam on the opposite side.

We have now to examine the manner in which the force of the shocks is diminished by the lead of the slide, and to what extent this remedy is effectual.

We shall confine our reasoning on this subject to locomotive engines, in which, as we have already observed, the strain brought upon the key of the piston by destroying the momentum of the latter, is very slight in comparison with that which results from the pressure of the steam on the piston, and which the key must necessarily bear during some portion of the stroke; for, supposing the effective pressure of the steam to be 50 pounds on each square inch of the piston, the area of the latter being upwards of 113 square inches when its diameter is one foot, the total pressure of the steam on its surface is more than 5600 pounds, while the strain due to the inertia of the piston, being under seven times its weight; if we suppose this to be 70 pounds, (which we believe to exceed the truth) is less than 490 pounds, or less than one-tenth part of the strain due to the resistance of the load, deduction being made for the friction of the piston. The connecting key of the piston must therefore unavoidably bear a strain of more than 5000 pounds while the steam is acting with its full force, besides that due to the inertia of the piston, which amounts, at one quarter of an inch from the end of the stroke, to 69 seventieths of the maximum strain due to that cause; and, since this is less than one-eleventh of the total strain at the end of the stroke, when no lead is given to the slide, the greatest amount which can be saved by cutting off the steam and admitting it on the opposite side of the piston at a quarter of an inch from the end of the stroke, is no more than one-seventieth of the strain due to the inertia of the piston, or less than one 700th part of the total strain at the moment of cutting off the steam.

It is therefore evident that the sudden jerks experienced by the key which connects the piston with the piston-rod, in consequence of the rapid changes in the motion of the piston, in as far as they are due to the inertia of the latter, do not afford a sufficient motive for giving a lead to the slide; and that this remedy is entirely ineffectual in diminishing them, in as far as they are due to the alternate action of the steam on the opposite sides of the piston, which is the immediate cause of nearly the whole amount of the evil; so that, if the piston could not be kept tight on the piston-rod without the lead, neither could it be with a lead of a quarter of an inch, when the length of the stroke is 18 inches.

Regarding the second reason, namely, that the steam may be admitted into the cylinder, and be completely ready to begin the next stroke when the piston is at the end of the cylinder, we are of opinion that nothing at all is gained in that respect by means of the lead, but that, on the contrary, it is attended with a slight disadvantage. Near the beginning of this paper we observed that, without any lead, a loss of pressure during a very small portion of the stroke ensues from the necessity of filling the waste space at the end of the cylinder with steam at the beginning of the stroke; but this loss is of very trifling amount. By a lead of one quarter of an inch this loss of pressure is avoided, for this gives sufficient time for the waste space to be filled with steam at full pressure by the commencement of the stroke; but by this means the resistance on the opposite side of the piston is increased, during the last quarter of an inch of the stroke, by whatever pressure the steam has acquired at every instant of that portion of the stroke. The amount of resistance so produced is greater than the loss of pressure at the beginning of the stroke resulting from the abovementioned cause when there is no lead. We do not, however, attach any importance to this circumstance, as the whole amount of loss either way is perfectly insignificant; we only mention it to show that the lead of the slide is not requisite, nor even advantageous, for the second reason assigned by the author of the paper above quoted.

With respect to the third reason, we do not think that so much can be gained as the author appears to suppose, yet, if there is any advantage in the lead, it is probably in beginning to get rid of the waste steam before the commencement of the stroke, so that, when the piston commences its stroke, there is but little waste steam before it to resist its progress, the steam beginning to be let out of the cylinder before it has driven the piston to the end of the stroke. Now there is clearly this advantage in beginning to let out the waste steam before the end of the stroke, that, supposing the time occupied in getting rid of the whole of it to be the same as without any lead, the portion of the stroke traversed by the piston during this time is less, because its velocity is on an average less; besides which, the resistance of the waste steam during the first portion of the time, namely, at the end of the previous stroke is thereby avoided, though at the expense of a part of the useful effect of the steam in the latter part of the stroke: indeed, by as much as the pressure of the waste steam at the beginning of the stroke has been diminished by the eduction port having been already some time open, by so much must its effective pressure have been reduced at the end of the previous stroke. We have also already mentioned the resistance of the steam let on to the front of the piston before the end of the stroke, which of itself nearly compensates the saving of part of the resistance of the waste steam at the beginning.

The preceding reasoning is only intended to prove that there is little or no reason, and certainly no necessity to give a lead to the slide in *locomotive* engines; for other descriptions of engine it is needless to say any thing, as no one would ever think of giving a lead in any but a locomotive engine. It might however be advantageous to give a lead to the eduction only, as by that means the saving of resistance at the beginning, would not be counteracted by the additional resistance of the steam admitted into the cylinder before the end of the stroke.

To return to the action of the steam in the cylinder. The whole effect produced during an indefinitely short period of time is equal to the pressure of the steam on the whole area of the piston multiplied by the distance travelled by the piston during that time, the pressure of the waste steam being considered as a part of the resistance, or total effect. This is true, although at some moments the resistance may appear less than the pressure of the steam, and at others infinitely greater: for the compensation is perfectly made by the momentum of the moving parts, which serve as reservoirs of power, absorbing, as it were, the excess at one time by receiving an increase of velocity, and giving it out again at another time, when the pressure of the steam is inferior to the resistance. But although the pressure of the waste steam is strictly a part of the resistance, yet we shall, in the following investigation, deduct its amount from the gross power of the steam, and consider the balance as the gross power of the engine, which will then be equal to the useful effect, *plus* the friction and other resistances *in the engine*. In our next paper we shall commence this investigation with the low pressure condensing engine, for which the calculation is the most simple, and then extend it to the other varieties of engine.

ARCHITECTURAL COMPETITION.

Sir,—The subject of Architectural Competition is one, which at this moment, should be more than usually interesting to members of the profession. I do not, therefore, hesitate to request your insertion of the following correspondence, which I think, it will be confessed, exposes as unsatisfactory a case as any of those recently so much commented upon.

In the early part of this year, a committee formed for building a new church at Cardiff, advertised for plans, offering premiums of 20*l*. and 10*l*. for the first and second best designs. In conjunction with my partner, Mr. Brandon, I submitted plans, with a specification and estimate. On the 11th June, we received the following letter:—

Cardiff Vicarage, 10th June, 1839.

Gentlemen,—The premium of 20*l*. offered for the best plan and design for a church in this town, having been awarded to you, I have great pleasure in forwarding you from the committee, an order for that amount on the London and Westminster Bank, of which I shall be obliged by your acknowledging the receipt.

I am, Gentlemen, your very obedient Servant,

T. Stacey. Hon. Sec.

In the course of two or three weeks after the receipt of that letter, we heard it rumoured that a Mr. Foster, of Bristol, was to be employed as *architect to this church.* Being at a loss to reconcile this statement with the announcement that our's was *"the best plan and design,"* we wrote to say, that if their subscription fell short of the contemplated amount, we should be happy to submit sketches for a building on a reduced scale. On the 25th June, we received the following letter.

Cardiff, 24th June, 1839.

Gentlemen,—I fear I have been guilty of an omission in my last communication, that has occasioned you some misconception relative to the proceedings of the committee for building the new church here. Had it occurred to me, the most obvious mode of putting you in possession of their intentions, would have been to send you a copy of the resolutions adopted at the meeting at which the first premium was awarded you. And no better mode occurs to me now. I therefore beg to subjoin a copy of that resolution:—

"It was unanimously resolved, that the premium for the best plan be adjudged to Messrs. Wyatt and Brandon, and that the plan and design of Mr. Foster, of Bristol, be adopted by the committee for those of the new church," &c. &c.

Whilst, therefore, the committee adjudged your design to be the best *according to the advertisement*, they thought it preferable to adopt one furnished by a Mr. Foster, of Bristol. I feel now, that this should have formed part of my last letter, but at the moment I wrote, it seemed to me *that my silence would have been interpreted by you as indicative of the resolutions of the meeting.*

I remain, Gentlemen, your very obedient Servant,

T. Stacey, Hon. Sec.

Why Mr. Stacey should have imagined that from "*his silence*," we were to suppose the committee had resolved upon this unusual course, I am unable to guess. We, however, addressed him on the 25th as follows:—

Sir,—We have to acknowledge the favor of your letter of the 24th inst. and to state the fact of our having misconceived the purport of your former letter. When you announced that the committee had adjudged us the "*first premium for the best plan and design*," it never for a moment occurred to us that the committee would take the unusual, and as we cannot help feeling the unjust course of employing another architect. Either our design was the best, *in accordance with your instructions*, or Mr. Foster's was. *If his accommodated 2000 persons, and was most applicable to your objects*, we think you did him an injustice in calling our's *the best*. If, on the contrary, our's was really *the best*, why not have done us the justice to believe that we were capable of altering that design, or producing another *quite applicable* to your wants? We cannot but think the resolution of the committee must have passed in forgetfulness of general custom and of the injurious effect *it must* have in competition generally. Surely, no architect of respectability would be found to expend time and money in designs where "the premium" was the only reward, and certainly not in a case where the amount of such premium is insufficient to cover the actual outlay in preparing those designs. It is only the superintendance of a building, which offers credit and remuneration to the architect proportionate to the thought and the anxiety expended on a meritorious design. * * * We beg to assure the committee, that these remarks are not written in a spirit of dictation, for to their decision we must, of course, bow; but it is not the less *our duty* to call attention to that which unexplained, implies either injustice on their side, or a stain on our professional character, for whilst it appears to the public that we have submitted "the best plan and design" you have received, they learn that *our* future services are declined, and an architect employed, *whose design was neither the first or second best*. We trust, therefore, that the committee will at least alter the wording of their resolution.

We have the honor to be, Sir,

Your obedient Servants,

Wyatt and Brandon.

The following letter acknowledges the receipt of our's of the 25th, and affords the satisfactory information that Mr. Foster is selected for the *highest premium* the committee could give, namely, their employment, because his "plan and design were not in accordance with the terms of the advertisement." This, certainly, is a curious specimen of justice, and will, no doubt, tend to impress upon the minds of future competitors, the *advantages* of strictly adhering to the instructions issued by committees.

Cardiff, June 27th, 1839.

Gentlemen,—I have had the honor to receive the favour of your letter of the 25th, and will not fail to lay it before the committee at their next meeting. But as it is not likely, from the progress of things, that I shall soon have an opportunity of doing so, I beg to state at once, and from myself, that the reason why Mr. Foster's plan and design were not awarded the first premium was, that they were not in accordance with the terms of the advertisement, and therefore it was, that your's were assigned the premium.

I have the honor to be, Gentlemen,

Your very obedient Servant,

T. Stacey.

One or two other letters passed, in continuation of this subject; that from Mr. Stacey, assuring us that the committee had not the least intention of "offering any mark of disrespect, or want of due consideration to the design of Messrs. Wyatt and Brandon, the merit of which they highly appreciate." On the 30th July we addressed Mr. Stacey.

Sir,—We have to acknowledge the receipt of your favor of the 29th inst., communicating the contents of a resolution passed by the Cardiff Church Committee. We regret the necessity of again troubling you upon this subject, but we must, for the last time, repeat our sense of the injustice done us; which, however unintentional on the part of the committee, is not the less apparent. It is only on the *understanding* that *all* the designs submitted shall be tested by the terms and conditions imposed by the advertisement, and that those designs which *do not comply with such instructions shall be rejected*, that architects compete. Unless all the competitors start from the same point, it is impossible that the race can be a fair one. Mr. Foster's plans, it seems, were sufficiently informal to disentitle him to the premium of 20*l.*, and yet these informalities are made to disappear, and he is awarded *the first premium, the superintendance of the building*. And the only premium, which in this case, was worthy struggling for. Surely this is not fair play! It was only on the faith, that the architect who received the first premium, would be employed to carry into execution any work the committee might erect, that you received plans at all. It is (unless specially excepted, as in the case of the competition for the Royal Exchange now going on,) the basis of all understanding between committees and competitors—once destroy this, and you put an end to competition. In the case of the Royal Exchange, the premiums offered are 300*l.*, 200*l.* and 100*l.*, with this clause, "That if the architect who receives the first premium should not be entrusted with the building, he shall receive an additional sum of 500*l.* if his designs are carried into execution. The committee having power to retain the drawings for which the premium is awarded." Now here there is no understanding, and the fact of their considering it necessary to make these conditions, implies that without them architects should not be invited to compete. Under the circumstances of the case, we have no desire to retain the premium *thus* awarded us, and are prepared to return it, upon being informed to whom it should be paid.

We have also to request you will give directions for our drawings being returned; under any circumstances, they are not the property of the committee, and as they are going to build on Mr. Foster's plan, our design can be of no service to them, unless for the purpose of adopting any arrangement or feature of merit they may be thought to possess; a proceeding which we are unable to suppose a committee of gentlemen would sanction.

We have the honor to be, Sir,

Your obedient Servants,

Wyatt and Brandon.

To this letter, on the 28th November, we received the following reply:—

Cardiff Vicarage, 27th November, 1839.

Gentlemen,—I beg to forward you the following copy of a resolution of the committee appointed for the erection of a new church at Cardiff, passed on Monday the 25th instant.

The secretary having laid before the meeting a letter from Messrs. Wyatt and Brandon, commenting again on the adjudication of the premium for the best plan, it was resolved:—

"That the secretary be directed to return Messrs. Wyatt and Brandon their plans as they desire, and to inform them that the amount of the first premium awarded them, which they decline to retain, may be paid into the London and Westminster Bank, to the credit of the treasurer of the Cardiff New Church Building Fund."

In pursuance of the foregoing resolutions, I forward your plans by this days' mail, carriage paid. I desire you should understand that the committee meeting of the 25th, was the first that has been held since the receipt of your letter of the 30th July, otherwise it would have been replied to earlier.

I have the honor to be, Gentlemen,

Your most obedient Servant,

T. Stacey, Hon. Sec.

Here closes the correspondence. We have received our designs, and the premium has been returned. Mr. B. Ferry, to whom the second premium was awarded, viewing the matter in the same light that we did, remonstrated by letter, against this act of the committee, and informs me, that the replies he received as to the grounds on which Mr. Foster is employed, were "equally unsatisfactory" with our own. It is always difficult in cases where one's own interests or feelings are concerned, to take an impartial and correct view. And possibly this case, which to any eye presents an *inconsistent*, if not an unjust appearance, may have occurred before, and may not be thought to call for the remonstrances we deemed it right to make. Its consideration, however, can do no harm to those who may hereafter engage in competitions, and if, by the course adopted we have tended in however slight a degree to assert the independence and correct feeling of our profession, the end we had in view will be fully realized.

I am, Sir,

Your obedient Servant,

Thomas Henry Wyatt.

75, Great Russell Street, January 1840.

REMARKS ON RAILWAYS,

WITH REFERENCE TO THE POWER, &c. TO BE EMPLOYED UPON THEM.

(Continued from page 6.)

Having in the last number of the journal disposed of railways unfavourable to locomotive engines, we will proceed to examine level railways, with reference to the power to be employed on them, as in the former case. I will take an example lest it be said I make the case suit the principle, instead of making the rule apply to the case.

The Sheffield and Rotherham Railway has been completed about eighteen months; it will elucidate my views as well as any other, and because I am better acquainted with it than those at a distance, I will therefore take it as our example. As truth is what I wish to elicit by these remarks, perhaps it will be the clearest way to say at the commencement what I intend to prove; by so doing your readers will be enabled to judge how the arguments which I bring forward bear on the case.

It is that in the example we have taken, and in any similar one, we can have a *cheaper, more efficient and better railway* by having endless ropes, and stationary engines, than by locomotives.

To prove this, it will be necessary to go into calculations; but to make them as short as possible, I will only give the results, reserving to myself the opportunity of giving them at full length, should any of your readers deny their correctness. First, as to "cost of the railway." It is said the Sheffield and Rotherham Railway has cost already £110,000, about £80,000 of which would go for constructing the railway, viz., embankments, excavations, &c., and for permanent rails. It will not, I think, be disputed that the embankments and excavations on this comparatively level country have been made at a cost of at least £33,000 more than they would have done had fixed engines been the moving power; and as some of the engines upon this railway weigh 16 tons, we may safely take off £7,000 from the first cost of the rails and chairs, making, with the sum first mentioned, £40,000 or the railway, would have cost £40,000 less than it has done had fixed engines been the power contemplated. The interest of this sum, at 5 per cent., is £2,000 per annum. So much for the cost of the railway.

We will now go to the second part of our subject, viz., "more efficient." An engine and tender will weigh about 20 tons; suppose we call the engine 50 horse power, we shall have, at 30 miles per hour, a power of $12\frac{1}{2} \times 50 = 625$ lbs., which will take, on a level railway, nearly 56 tons, 20 of which is taken up by the engine and tender, leaving 36 only conveyed by an engine of 50 horse power at 30 miles per hour.

To convey 36 tons by the stationary system, it will require a rope $3\frac{1}{2}$ inches circumference: 2 miles of it would weigh about 4,600 lbs. Messrs. Walker and Rastric take the friction of the rope to be $\frac{1}{22}$ part of its weight; I see no reason to vary from their estimate; but as Messrs. Robert Stephenson and Joseph Locke, whose bias would be against stationary engines, take it as $\frac{1}{12}$ of the weight. I will, in deference to the opinion of these latter gentlemen, take it to be $\frac{1}{15}$, which is about half way between the one and the other; $\frac{1}{15}$ of 4,600 lbs, is 306 lbs. The friction of the train is 403 lbs., together 709 lbs. which divided by $12\frac{1}{2}$, the power of a horse at 30 miles per hour = 56 horse power, or 6 horse power more than the locomotive. But the locomotive would have to get its steam up before working, and there would be fuel in the fire-box when it had arrived at the end of its journey; I shall take it working 5 minutes before and 5 minutes after, which will make, with the 15 minutes in performing the journey, 25 minutes, or what is about the same thing, 83 horse power for 15 minutes.

Though the stationary system requires an engine 56 horse power, yet, as the 72 trains per day, 36 tons at a time would only occupy, in the two miles worked by each engine 24 minutes per hour, it would only be needful to have them 36 horse power. The distance from Sheffield to Rotherham, 6 miles, is divided into 6 stages, requiring an engine at every other stage; but as it would be more convenient to have one at each end, it will require 4 engines. These 4 engines are employed the whole of the 12 hours, without any intermission, in pumping water out of one reservoir into another fixed 40 or 60 feet above it; the water in the upper reservoir is allowed to run over a water wheel as it is wanted to move the trains, which, as before stated, is about 24 minutes in every 60, by which the 36 horse power engine becomes increased to 90 horse power, or there will be as much water pumped in the 60 minutes by the 36 horse power engine as would supply a water wheel of 90 horse power, if there were no waste; but the loss from this cause, and from friction, will be 33 per cent., which will reduce the engine to 60 horse power, or 4 more than is required; it appears, then, we only require engine power of 144 horses. It is hardly likely that 3 trips per hour each way, for 12 hours, would be made by fewer than 6 locomotive engines kept ready all the time, which would be equal to 300 horse power than twice as much as the stationary, and certainly more than four times the expense in fuel, and by using coke instead of coals, and being high pressure instead of condensing engines.

We think the second part of our proposition "more official"—is clearly made out. There remains now the third, viz., "a better railway;" this will be more difficult to prove, it is such a comprehensive term; but we don't fear being able to do so.

If we can travel as fast, or faster, at a smaller expense, injure the rails less, be less liable to accidents, either to the machinery or rails, have no more stoppages from the machinery getting out of order, and have such stoppages as do occur, shorter, and sooner remedied. If we can insure all these at about half the annual expense in repairs, are we not justified in saying we could have a better railway, I will begin with "speed;" in wet weather, on the Sheffield and Rotherham Railway, it is the practice to put sand on the rails, where there happens to be a slight inclination, to make the wheels bite, and so much are the wheels in the habit of slipping on all railways, that Mr. William Vickers, a merchant in Sheffield, who has a good knowledge of mechanics, and is pretty well acquainted with the working of railways, has been induced to take out a patent for the plan of connecting all the wheels together by means of a belt or strap. If they slip they must lose speed, and injure the rails at the same time. With regard to the speed of the stationary plan, it depends upon the speed of the engine, and is only limited by the strength of the materials of which the rope, pulleys, engines, &c. are constructed; and were there no such thing as resistance of the atmosphere there would be hardly any limit to it. Then comes the relative expense at which this can be done. If we increase the speed of the locomotive, the engine and tender will form a much larger proportion of its load than at present, because it will require a greater quantity of fuel and water on account of the increased power of the engine. The engine would have to be made stronger and heavier to take the same load. The rails, chairs, and every thing connected with them would cost more in repairs, because of the increased speed and weight of the engine, and the engine itself would be sooner worn out. While, on the stationary plan, the only difference would be an increase in the power of the engines, greater strength, of rope and pulleys, and an additional wear in the two latter, the rails, chairs, &c. remaining the same.

I find I am getting unnecessarily into the *minutiæ* of the subject. All these things are important, no doubt, but will be wearisome to your readers to go through. I will therefore confine myself to the comparative safety and annual expense of the two systems. The greater the weight in motion, the less it will be influenced or impeded by obstructions, and this will render it more liable to get off the rails at the curves, and make it more difficult to stop. It appears that locomotive trains will always have 20 tons more weight, as already stated, than the stationary system, the conclusion is obvious. The large wheels of the locomotive engine would have a tendency to run off the rails, the ropes of the stationary plan would tend to keep the carriages on. The engine and train being independent of any other, would be in danger of coming in contact with other trains, unless those trains were at a considerable distance, and every collision without great care would throw carriages in the train of one or both of them off the rails, and occasion great delay to say the least of it. The stationary plan might have a hundred trains, a hundred yards of each other, and they would never approach nearer, this needs no comment. In comparing the annual expense of the two, it will not be necessary to ascertain the expence of each, but only where they differ, to estimate the amount of each. The locomotive engines cost about £1,300 each, and if they are fully worked will cost £300 per annum in repairs, or if half-worked £150. (Let Demetrius and the Craftsmen deny this if they can.) We will take them to be half-worked, there would then require 5 engines and one spare engine, making 6 engines in constant work, so that the cost per annum would be $6 \times 150 = £900$ for repairs. The engines will last not more than nine or ten years. We will take them at 13 per cent. on 6 engines, which will be £1,014; the fuel we will estimate at $1\frac{1}{4}$ per ton per mile, including waste at each end, we shall have to reckon 50 tons moved in this case and not 36, but as the coke and water is consuming, I have reckoned 50 tons, 72 times 6 miles for 312 days, which amounts to 6,739,200 tons conveyed one mile, $1\frac{1}{4}$ lb. per ton on this will be 3,760 tons of coke, which is 14s. per ton, the amount of this will be per annum £2,632. I shall take the enginemen, firemen, &c., to be the same in both systems, therefore need not take them into account; the expence, then, of the locomotive system from these three items will be £4,546 yearly.

The stationary plan has 4 engines of 36 horse power each, on the same principle as those in Cornwall, viz., work with 50 lbs. steam, and cut off the steam at one-fifth of the stroke, these engines consume $2\frac{1}{4}$ lbs. per hour for horse-power; 12 hours per day, 312 days, it will give per annum about 602 tons at 5s. per ton, or £150 10s.

The ropes will not require renewing oftener than once in twelve months because there are not jerks or stoppages at the stations, the cost of this, after deducting the value of the old, will be £525. The four engines, engine-houses, and machinery, would cost £8,000, at $6\frac{1}{2}$ per cent. would be £520. The annual repairs to boilers, engines, and machinery, taken as by Messrs. Walker and Rastric, including hemp, oil, and tallow, at 14s. 8*d.* per horse power, will be £406 8s. The interest, wear and tear of pulleys would be £300, oil to pulleys, and men to grease them, £144, all which sums amount to £1,745 18s.

The whole yearly expense of the stationary system amounts to £1,745 18s. The expence of the locomotive system, £4,546, making a difference in favour of the stationary of £2,800 2s., which sum, added to the £2,000 per annum saved in the first cost of the railway, amounts to £4,800 2s. If the saving of £4,800 per annum does not speak to the pockets of the shareholders, nothing I can say will do it. If gentlemen of fortune wish to have railways, let them have locomotive engines upon them by all means to show to their wives and daughters, but if men of sense and men of business wish to have their shilling's worth for a shilling, let them search and see if these things are so.

Diogenes.

Sheffield.

(To be concluded.)

ENCROACHMENTS AND RECESSIONS OF THE SEA.

It appears that the tendency of "*the sea to preserve its parallel*," has been pointed out in No. 27 of the Journal as the origin of the encroachment and recession of the sea, and that the action of the influx of water is increased in bays in proportion as the projecting point to the westward is greater, while it is assumed that the filling up of bays and cutting of headlands are equal. The meeting of the tides from the Northern and Southern Channels to the eastward of Hastings, renders a reference to the geological facts to the westward most advisable.

The beds of sand, sandy rock, and clay, denominated the Wealden formation, are supposed to dip from Hastings to Beachy Head, and to disappear under the chalk at that point. The outcrop of the highest sand-rock bed is visible from thence to the Sea Houses, East Bourn, but in the interior, the height of the beds above the sea level seems in some proportion to their hardness. Pevensey Castle is placed towards the end of one of these low ridges, so formed, and Pevensey Level consists, judging from the drains, of the outcrop of the clay beds, and not of the detritus of the chalk cliffs to the westward. Romney Marsh is sometimes considered as a more modern deposit of silt; its position, in some geological maps, is in front of that part of the Hastings sand, dipping easterly from the anticlinal line near Hastings; it is said to have successive ranges of beach banks, of a form nearly corresponding with the present coast line. If these opinions are correct, it differs essentially in its formation from Pevensey levels, where, I believe, a small extent only of beach, covered with grass, exists at the eastern end. The accumulation of beach at Langney point, perhaps amounting to 1000 acres, is at a lower level, and is almost as bare of grass as the shore on which the sea now beats, while its character is similar in all points to the mass of beach at Dungeness.

It has been most distinctly proved, that an ancient raised beach exists around the coast of Cornwall and Devon elevated in different sites from 5 to 30 feet or more, and covered with a Grauwacke detritus termed alluvial by Dr. Buckland.

At Brighton there seems an equally distinct trace of an equivalent raised beach covered by a diluvial chalk detritus, as due to a similar cause in different sites. Perhaps the grass-covered beach banks of Romney Marsh and Pevensey Level, are due to the same geological epoch, and the accumulations of beach at Languey point and Dungeness belong to the present era.

Previous to the admission of any arguments derived from the beach at Hastings Bridge, it must be proved to be a portion of the present sea beach, as its site and height above the sea would suggest the idea of its forming a part of a raised beach of a former geological period.

In reference to the question of equal cutting and filling, it has been shown by geologists, that the waves are the cutting agents of the sea in the destruction of cliffs, and that the tides or currents sweep the finer particles into deeper water, and leave the harder part on the shore, which are rounded into beach; the whole coast, whether high or low, is fringed with a variable quantity of beach, which is driven along the coast in proportion to the diagonal blow of the waves, and consequently the mass is in motion eastward, as due to the mean excess of the westerly over the easterly waves.

The effect of groins is easily seen; the beach is collected on the weather side, while the lee side becomes bare; hence equal waves have a greater cutting effect on the softer materials of the exposed shore or cliff, and less on the side protected by the accumulation of beach, and in their construction, the principle to be regarded is the retardation of the exact quantity of beach requisite for the protection of each spot, allowing its regular passage either way; the groin referred to at Hastings is probably either too large, or too high at the outer end—the result is inevitable, the shore on each side will be overprotected, or overbared, alternately, according to the direction of the wind.

My object has been rather to question the data assumed than to attempt to elucidate this subject by a reference to the numerous elements essential for that purpose, partly with a hope of inducing civil engineers, to measure and record clearly the geological facts which may happen to come under their notice in the course of their professional labours.

E.

ON THE COMPARATIVE POWER OF STEAM ENGINES.

Sir—Though I have read with great pleasure the communication of Mr. Armstrong on the comparative effects of the Cornish and Lancashire system of working steam engines, yet I must object to the accuracy of the estimate of the gross horse power of the East London Water-works engine, and I trust the following observations will induce others to take into consideration the propriety of confining the term Duty to the distinct and definite meaning in which it has been employed in a large mining district for a longer period, than the existence of factory steam engines. His paper is entitled, "On the Comparative Effects," the table is headed "Comparative Duty;" the pounds raised one foot high per minute $\div$ 33,000 are termed "Gross Horse Power," while this same quantity 194 is termed "Net Effective Power," previous to the deduction of one-third for the resistances of the shafting; yet each is actually derived from the same elements, viz., the average steam pressure taken by the indicator in the Lancashire engine, and the supposed gross load + an allowance for "friction of the engine itself," in the Cornish engine $\times$ in each case by the space in feet per minute for gross horse power. The gross pressure of steam whether observed or calculated, is equally capable of being referred to the variable time of the consumption of a bushel of coal (94 pounds), but then such a word as Efficiency would be useful in distinguishing it from Duty. See Phil. Trans., 1827.

Duty as introduced by Watt, and retained in Cornwall, is founded on different elements, viz. the nett work performed clear of pitwork or shafting resistances, $\times$ by the space of motion per bushel of coal, it is always calculated, but if the water was measured or weighed, it might be called active duty: the usual mode of obtaining the load in the shaft is by squaring the pump diameter in inches, $\times$ by the lift in fathoms, $\times$ by 2·0454 pounds, the weight of a cylinder of water one fathom in length and one inch in diameter: the omission, however, of the two last decimals, only affects the three last figures of the duty in millions.

Duty and gross power are hence the extremes, while gross power *minus* engine resistances, and duty *plus* pitwork or machinery resistances become respectively nett power, = engineer's horse power, and gross work performed, and these on a statical view are equal to each other—the word effect will be found a convenient term to distinguish gross work done from duty. It has always been necessary to ascertain whether the beam leverage is equal, if not so, due allowances must be made for the differences; it will be also convenient to use the word pressure as equivalent to force, and force $\times$ space as power, while gross and nett load become respectively effect and duty.

In the arrangement of the East London Water-works engine, a weight of 29 tons is lifted at the outer end of the beam during the in-door stroke, but not without some packing friction, as well as a column of water on the lower valve of a diameter equal to that of the plunger pole—together, these form the gross load on the in-door or acting stroke. During the out-door stroke the weight returns and lifts the water above the lower valve, overcomes friction, &c. &c. As friction increases in bad pitwork, at least, as fast as the deficient water delivery—while the reverse takes place in good, the calculated duty of pumping engines probably bears a closer approximation to the whole work done, or effect, than might be expected.

In all cases I am inclined to think the pitwork resistances exceed the decrease due to deficient water delivery. There are no data for duty calculation, except by valueless approximations. I shall however submit to public opinion the following estimate of the gross power of this engine, in comparison with that derived from the "Average Steam Pressure, taken by indicator," in the Lancashire factory engine. I conceive the allowance of half a pound per circular inch for the "friction of the engine itself," a quantity scarcely sufficient to overcome the steam or vapour pressure due to the temperature of the water in the condenser.

Weight in-doors 29 ton - -	= 64,960 lbs
Stuffing box friction, say - -	= 501
41² inches × 4 fathoms × by 2·0451 lbs	= 3,439
Gross load in lbs. - - -	= 68,900 load for effect.
Quarter of effect load = 1-5th gross power - - -	= 17,224 engine's resistances.
	= 86,124 lbs.

Gross steam pressure on the shaft.

In a recent communication by Mr. Wicksteed, relative to the success of the Harvey's and West's patent double beat valve, the pump stroke is stated to be nine feet, and consequently 90 feet of motion at 10 strokes per minute. Taking the gross pressure in the shaft at 86,124 lbs. × 90 feet, = 7,751,160 lbs. one foot high, we have $\frac{7,751,160}{33,000}$ = 235 gross horse power.

In consequence however of the prevalence of the method among practical engineers of deducting the resistances due to vacuum, imperfections from the observed average indicator pressure, and calling the result average steam pressure (a quantity I should feel disposed to term a worthless mean between gross and nett power of no practical value, and absolutely injurious in tending to mislead in estimates of pounds of water used in the cylinder), it would not be fair to contrast that which is proposed to represent the gross power of a good Cornish engine, until it has been ascertained whether the observed or calculated gross steam power in the Lancashire factory engine has been given.

The error will be in its favour if an allowance is added of $\frac{1}{12}$, perhaps, for this practise, while the engine's resistance, ought perhaps to be taken higher than one-fifth of the gross power to allow for the greater friction of smaller cylinders working at a high power, if required: it appears to me that the one-third allowance should be deducted from the nett power thus obtained, for a duty estimate, giving 20 millions as a rough approximation.

		34,754,432
One-twelfth - - - - -	=	2,896,202
		37,650,634
One-fifth engine resistance -	=	7,530,126
		30,120,508
One-third shaft-work - - - -	=	10,040,169
Duty - - - - - -	=	20,080,339

My object is to recommend the simple classification here used, subject to any corrections of engine or pitwork resistances, conceiving if attention be called to this subject, it will soon lead to the adoption of correct methods, which will facilitate the connection of theoretical and practical views of steam engines.

I am, Sir,
Your obedient servant,
JOHN S. ENYS.

January, 1840.

Discovery of a Cavern.—As the workmen were employed in blasting the rocks near the foundation of one of the Clifton suspension bridge piers, a day or two since, they discovered a small opening. On its being examined, it was found to lead to a small cavern extending fifty-seven feet below the surface of the ground, nearly in a perpendicular direction. The exploration was made by Dr. Fairbrother, with the assistance of one of the workmen. There were several chambers at intervals, but the descent is difficult, and can only be made with the assistance of ropes. The air is tolerably pure, so that the candle burnt freely during the whole of the time (nearly two hours). At the bottom, the air was found to be excessively hot, so that the perspiration flowed freely. In other respects the cavity presented nothing remarkable, beyond the ordinary appearance of fissures formed by the raising of the strata of lime-stones by some extraordinary convulsions of nature.

THE CORNISH ENGINE,

AT THE EAST LONDON WATER WORKS.

As the above engine is likely to become an object of considerable interest to engineers, we determined upon paying a visit to the Water Works at Old Ford, for the purpose of obtaining correct information as to her dimension and mode of working. On our arrival at the works, Mr. Wicksteed, the engineer to the Company, immediately granted us permission to inspect the engine, and kindly offered to afford any information we might require, and for this purpose, accompanied us on our view, and readily answered every enquiry, explaining at the same time, the general working of the engine. Before proceeding to the details, we must offer our congratulations to the directors of the Company, on the successful performance of the engine, and we feel happy to find that the very large pecuniary saving in fuel annually, by the adoption of the Cornish engine, will amply repay them for the spirited manner in which they came forward to support their engineer against the almost unanimous opinions of the London engineers, who generally pronounced the boasted performances of the engines in Cornwall to be preposterous. Through the kindness of Mr. Wicksteed, we are now enabled to lay before our readers practical data of the economic working of the engine at the East London Water, Works, which we believe, is the first and only Cornish engine that has been yet erected in the metropolis.

The engine was originally intended for a Cornish mine, known by the name of the "East Cornwall," it was designed by Mr. West, a member of the Institution of Civil Engineers; it is upon the same principle as the one designed by the same gentleman, erected at the Fowey Consols Mines, which has for several years past done more duty than any engine in or out of the county of Cornwall, and manufactured by Messrs. Harvey and Co. of Hayle; it was purchased by the East London Water Works Company in 1837, and removed to London and fixed in its present situation by Messrs. Harvey and West, who have, by the superiority of the working of this engine, and the faithful execution of their contract, given most unqualified satisfaction both to the directors and to Mr. Wicksteed.

Dimensions of the Engine.—The diameter of the steam cylinder is 80¼ inches, and length of stroke, 10 feet 3 inches; the steam is generated in the boilers, under a pressure of 35lb. on the square inch above that of the atmosphere, and cut off when the piston has performed about one-third of its stroke, it then expands during the remaining two-thirds, and in the succeeding stroke is condensed to form a vacuum on the opposite of the piston, to which it passes through the equilibrium valve in the return stroke, the engine being *single acting.*

By the use of the apparatus called a *cataract*, the engine can be made to work from one (or less) to ten strokes per minute, as may be required. According to the calculations of Mr. Armstrong in our last Journal, the power of the engine is equivalent to 206½ horses, and by the statement of Mr. Enys in the present number, 235 *gross* horse power. Mr. Wicksteed, however, informs us that the actual weight lifted is 66,443 lbs. an average height of 9 feet each stroke, which is equal to 18·12 horses' power when the engine works one stroke per minute, or 181·2 horses' power at 10 strokes per minute, a velocity which Mr. Wicksteed deems the greatest *this* engine should be worked at.

Dimensions of the Pump.—The diameter is 41 inches, length of stroke 9 feet 4 inches, quantity of water lifted at every stroke 82·5 cubic feet, or about 14¼ imperial barrels, which is a week's average supply for a house. The plunger-pole of the pump, is loaded with about 29 tons over and above the other end of the beam, and this is the weight the engine has actually to lift at every stroke.

We were very much pleased with the quiet action of Messrs. Harvey and West's patent valve, there we felt any perceptible vibration, although we stood close to the pump; we have given the drawings and specification of the valve in another part of the Journal.

The steam is generated in four cylindrical boilers, 27 feet 8 inches long and 6 feet 5 inches diameter, constructed on Mr. West's Cornish plan; the tops of the 4 boilers are covered over with fine ashes, to prevent the loss of heat by radiation. The area of the boilers exposed to the action of the flame and heated air, is very great; and the furnaces are constructed with a large surface of fire grate, in proportion to the coals consumed, for the purpose of adopting the principle of slow combustion, which is here carried out to its fullest extent, so much so, that when the furnace doors are opened, the smoke at times comes out of the furnace doors into the stoke-hole.

We must also state that the steam cylinder is surrounded with a jacket, which is filled with steam from the boilers, and there is another jacket, or casing of boards, the interval being filled in with ashes, 17 to 18 inches in thickness; all the steam-pipes are also well cased with patent felt, or ashes in boxes.

The following particulars will show the working of the engine for 18 weeks, during which period it worked 2,923¼ hours, and made 1,012,353 strokes, at the average rate of 5·77 per minute, it raising 13,982,912 barrels of water, (of 360lbs. each barrel,) 112 feet 6 inches high, with the consumption of 361 tons, 15 cwt., 1 qr., (= 810,348lbs.) of coal of inferior quality, being the refuse or screenings of Newcastle coal, which has passed through a screen of ¾-inch thick mesh. By adopting the method of slow combustion, they are thus enabled to use the screenings, which costs only 17*s.* per ton delivered, whereas the superior coal required for rapid combustion, would cost 23*s.* or more.

During the same period, a condensing engine of the ordinary construction made by Boulton and Watt, with a cylinder 80 inches diameter and stroke 8 feet, with a pump 27¼ inches diameter and stroke 8 feet, worked 1,315½ hours made 1,152,124 strokes, raised 5,116,385 barrels of water, and consumed 275 tons, 17 cwt., 3 qrs., (= 617,988lbs.) of coal as above.

The Cornish engine works constantly under the same pressure, while the pressure in the Boulton and Watt engine is constantly varying, never exceeding the former, but on the average, less.

The Cornish engine worked night and day during the above period, with occasional stoppages, while the ordinary engine worked by day only; but the work of two other engines, on Boulton and Watt's construction, which worked night and day during the corresponding weeks of the previous year, was as follows:—They worked for 2,938¼ hours, and made 2,068,130½ strokes each; they raised together 9,309,362 barrels of water, and consumed 568 tons, 1 cwt., (= 1,272,432lbs.) of *best* coal.

Before the Cornish engine was erected, the East London Water Works Company had, in addition to the water-wheels at their Stratford and Lea Bridge Stations, four steam engines, besides an extra one, which worked during the summer months:—viz. two engines of 30-horses power each, which worked 24 hours; and two of about 95 horses power, which worked, upon an average, 12 hours *per diem*, the extra one was of 70 horses power, and worked occasionally in the summer. The consumption of coal amounted to 3,126 tons per annum, which was about £3,700., while the present engines, viz. one Cornish engine, working 24 hours per day, and averaging six strokes per minute, and one large Boulton and Watt engine, working 60 hours per week, calculating from the 18 weeks' consumption for both engines, the annual consumption will be 1,941 tons, which cost 17*s.* per ton, or £1,649. 17*s.*, thus effecting a saving of £2,050. per annum.

If 66,143lbs. be taken as the actual weight lifted at each stroke, (independent of friction and resistance of the engine,) and multiplied by 9 feet, the average length of the stroke of the pump, it will give 597,987lbs. lifted one foot high at every stroke, if this quantity be multiplied by the number of strokes, the engine performed during the eighteen months, and divided by the consumption of the fuel during that period, it will give: $\left(\frac{597,987 \times 1,012,353,}{810,348}\right)$ 747,054lbs., as the *useful effect*, raised one foot high by 1lb. of coal or 70,223,076lbs., by one Cornish bushel of 94lbs. of coal. It should be observed, that the amount of coals herein given, includes the coals used to keep up the steam whenever the engine stopped during the period mentioned.

In order to secure themselves against receiving inferior coal, the Directors have entered into a very peculiar contract (which we would recommend to the notice of other companies) with their coal merchant to supply them with coal of the same quality throughout the year, he guaranteeing that above 73 million pounds of water shall be raised one foot high by the consumption of 94lbs. of coal, which is equivalent to about 2½lbs. per horse power per hour; or in case of the average duty of the coals not amounting to so much, a proportionate reduction is to be made in the amount to be paid to him.

We trust the foregoing statement will prove interesting to the readers of our Journal. We should have been pleased if we could have presented engravings of this engine to our readers, but we do not so much regret the want of them at present, as we should if Mr. Wicksteed had not informed us that he intends to present complete drawings of the engine and boilers to the Institution of Civil Engineers, with a report, as soon as he has obtained some farther facts which he deems of the utmost importance, namely, the actual quantity of water evaporated by a given weight of coals, the quantity of water passing through the cylinder in the shape of steam to produce the effects stated, and in addition also, the same facts as regards a Boulton and Watt engine, that a fair comparison may be made between the two systems of expansion and non-expansion, and also to prove how much is due to the superiority of the boilers (if any), and how much to the mode of *using* the steam when generated.

The system adopted in Cornwall of reporting to the public every month the duty of the engines, has, we have little doubt, led, by exciting emulation, to the perfecting of the expansion engine, and if in other parts of England the same system were adopted, there is no doubt the public would benefit, as well as those manufacturers whose desire it is to make the best engine, and we therefore offer to those interested in the subject to publish in our Journal the reports forwarded to us. We have little doubt of having a monthly report of *the* Cornish engine, and we should like to have reports of others to compare with it.

MEMOIR OF DAVIES GILBERT, ESQ.

(From the West Briton.)

Davies Gilbert, Esq., D.C.L., late President of the Royal Society, was Hon. F.R.S E., F.A.S., F.L.S., F G.S., F.R A.S., President of the Royal Geological Society of Cornwall, Hon. Member of most of the provincial societies in the Kingdom, and of many on the Continent; he was also many years Member of Parliament for Bodmin, our county town, and was truly known as the Father of British Science. He was the only son of the Rev. Edward Giddy, of St. Erth, the representative of the respectable family of Giddy, of Nanteavallan, by Catherine, only daughter and heiress of Henry Davies, Esq., of Tredrea, only survivor of the ancient house of Davies, through whom he was connected with the noble family of Sandys, and that of Noyel of which the well-known Attorney-General was a member.

When a child, his precocious talents were the theme of the extensive circle with which his father, as chairman of Quarter Sessions, associated. His preliminary education was conducted at home; and at a very early age he contracted an intimacy, which continued until death, with the Rev. Malachy Hitchens, vicar of St. Hilary, a gentleman of high and well-deserved celebrity as a mathematician and astronomer, and as editor of the "Nautical Almanac." This acquaintance, without doubt, materially added in determining his mind to mathematical pursuits, in which he was afterwards so greatly distinguished. His academic education was received at Pembroke College, Oxford, to the funds of which he has been a liberal donor.

The introduction of Mr. Watt's celebrated improvement in the steam-engine into the Cornish mines, and the disputes between that great mechanical philosopher and the late Mr. Jonathan Hornblower, of Penryn, as to the economy and mode of applying the principle of working steam expansively, and which has since been carried to greater extent, and with a more remarkable economy of fuel in this county than any where else, early attracted Mr. Davies Giddy's attention; and the various subjects embraced in its perfect development formed a noble field for the employment of his rare mathematical attainments. The expansive action was employed by Mr. Watt in a single cylinder, but Mr. Hornblower used two. It was, however, far more readily made out in theory than it was acknowledged in practice, that by the use of one cylinder only the same mechanical advantage is obtained, avoiding the additional friction which a second cylinder would entail. The plan of Mr. Hornblower was, after a silence of several years, revived by Mr. Woolf: but it seems by general consent and experience, and by universal practice, to be now admitted that Mr. Watt's is the preferable mode.

Mr. Davies Giddy was solicited by the county at large to take an active part in the determination of the duty performed by Mr. Watt's engines—a task for which his genius and inclination peculiarly fitted him; and in conjunction with the late Captain William Jenkin, of Treworgie, he made a survey of all the steam-engines then working in Cornwall.

An indifference to the labours of authorship, provided the results of his inquiries were available to the public without appearing in print, prevented the investigations of these most important subjects from seeing the light in an authentic form until lately; the first of them appears in the Philosophical Transactions of the Royal Society in 1827—the second still more recently.

One of the most laborious and practically useful works which has distinguished that rich storehouse of intellectual wealth, the Philosophical Transactions of the Royal Society, is a paper by Mr. Gilbert, "On the Properties of the Catenary Curve." This fine example of mathematical inquiry was published whilst the celebrated engineer Telford was preparing his materials for the construction of that stupendous national work, the Menai bridge; and it affords one of the finest tributes on record to the labours of the philosopher in his closet, that after the appearance of Mr. Gilbert's memoir, the engineer caused the suspension chains which had been prepared and completed to be again taken in hand and lengthened by about thirty-six feet. The manner in which this magnificent structure has stood, proves that the principles on which it was constructed are perfectly accurate, but that its weight is insufficient to stand the storms to which it is exposed, without a vibratory motion, which is injurious to its stability.

One of the most remarkable incidents in Mr. Gilbert's life was his discovering, patronising, and encouraging the early struggles of Davy (afterwards Sir Humphry), whose introduction to public life, and to other friends, who brought him, his genius, and ability into notice, was due to his active and unvarying friendship. This is, however, matter of history, and most of our readers are acquainted with it.

In 1828 Mr. Gilbert was, by acclamation, called to that pre-eminently honourable station, the chair of the Royal Society, to which his profound learning and scientific researches, no less than his distinguished personal fitness, recommended him beyond every other person as the proper successor of Davy in the chair of Newton. This conspicuous place, at the head of British, and we may say European, science, Mr. Gilbert held, for about seven years, with the highest honour to himself, and the greatest utility to that learned body. It is a case without parallel, and one of which, as Cornishmen, we are justly proud, that we have furnished two succeeding Presidents of the Royal Society. During his Presidency, Mr. Gilbert was a liberal donor to the society's funds, and he extended a large and an enlightened patronage to every object worthy of the illustrious body over which he presided. He resigned the chair in favour of his Royal Highness the Duke of Sussex, who is now succeeded by the courteous and learned Marquis of Northampton.

In his native county, to which he has ever clung with most tenacious affection, in 1814, Mr. Gilbert founded the Royal Geological Society of Cornwall, (with a single exception) the oldest provincial philosophical society in England, and continued to preside over it until his decease; conferring on it an importance which it would not have otherwise attained, and extending its utility where, without him, it would have been unknown. To the other philosophical, literary, and charitable institutions of Cornwall, he was equally a liberal and enlightened patron.

The last literary labour of Mr. Gilbert's long, honourable, and useful life, was editing the "Parochial History of Cornwall," originally commenced by Mr. Hals, and continued by Mr. Tonkin. This work appeared but a year or two since, with copious addenda by the editor, and geological notes by Dr. Boase. It contains a vast mass of curious and valuable antiquarian research, and rich disquisitions on many subjects of the highest local interest. Its effect has, however, been impaired by typographical inaccuracies, which the printer's carelessness has overlooked.

The rare talents, abilities, and application of Mr. Davies Giddy, at an early period of his life, recommended him to the acquaintance of the leading scientific men of the age, and the principal inhabitants of the county; among these was the late Lord De Dunstanville, a nobleman as much distinguished by his discrimination as by his large and munificent liberality. Through his lordship's instrumentality, Mr. Giddy was returned to Parliament for the borough of Bodmin, in 1807, after having sat as member for Helston; and the distinction thus conferred on him through, what we may not improperly term, extraneous means, was continued from an honourable appreciation of his own ability and worth, until the passing of the Reform Bill, in 1832, when his advanced age and increasing infirmities rendered him desirous of avoiding the turmoil of public life, and of retiring into the peace and tranquillity of his domestic circle.

Whilst in Parliament, there were few members more regular and assiduous in their attendance, than Mr. Gilbert; he generally, though not uniformly, supported the Conservative side of politics, but he seldom spoke, and was by no means an active partisan. His great learning and habits of business, recommended him to all parties; and he acted as chairman of a committee on the financial system, in the critical and difficult period when Lord Castlereagh was the ministerial leader in the Commons. The rectification of the national standards of linear dimensions and capacities, which was made a few years since, was undertaken on his motion for an address to the Crown on the subject. The bounty on the export of pilchards was long continued through his active interposition; and, indeed, every subject which in any way affected the interests of his native county, when it came before Parliament, ever found him at his post, an active, ready, and indefatigable advocate of her interests.

We have now seen him an illustrious philosopher, a learned historian, and an enlightened legislator; but the most distinguishing (and if we may use the language without charge of affectation), the most endearing character we have yet to mention, for it would be vain to attempt to describe it—his conversation; it was not brilliant—it was something infinitely beyond and better than mere display; it was a continued stream of the most profound learning and most exalted philosophy, adapted with exquisite taste to the capacity of his auditory, and enlivened with anecdotes to which the most listless could not but listen and learn. His manners were most unaffected, child-like, gentle, and natural. As a friend, he was kind, considerate, forbearing, patient, and generous; and when the grave was closed over him, not one man, woman or child, who was honoured with his acquaintance, but will feel that he has a friend less in the world; enemies, he cannot have left a single one. A Cornishman he was in every good sense of the word; the mention of a Cornish custom, of a provincialism familiar in his youth, would make the aged man young again; the scenes of his early years, tales of times long gone, were poured forth in delightful glowing language, the more touching from its hearty, earnest, unaffected, and simple elegance.

Within a few years of 1810, Mr. Davies Giddy was married to Mary, only child and heiress of — Gilbert, Esq., of Eastbourne, and took the name of Gilbert, instead of his patronymic of Giddy. This alliance brought a considerable accession of fortune to his already considerable paternal inheritance. By this lady, who survives him, he has had several children, but four only are now alive,—a son, John Davies Gilbert, Esq., a daughter, married to John S. Enys, Esq., of Enys, in this county, and two other daughters yet unmarried. Mr. Gilbert's age was, we believe, about seventy-four, and his long, honourable, and honoured life, crowned with peace, riches, and distinction, was in the bosom of his family.

"QUOT NOTOS, TOT HABUIT AMICOS."

WOODEN PAVEMENT.

Extract from Leitch Ritchie's "Glance at Russia in 1835."

The wooden pavement is, I believe, peculiar to St. Petersburg, and merits a description. It consists of small hexagons sawed from a piece of resinous wood, and laid into a bed of crushed stones and sand. These are fastened laterally into each other with wooden pegs; and when the whole forms a plane surface, the interstices are filled with fine sand, and then boiling pitch is poured over all. This pitch, from the porous nature of the wood, is speedily absorbed; and on a quantity of sand being strewed above it, the operation is complete, and a pavement constructed which is found to be extremely durable, and which seems to me to suffer much less injury from the frost than the stone causeway. The honor of the invention is due to Mr. Gourief, and I have no doubt he will ultimately see it adopted in most of the great towns towards the north. It is the custom of the peasantry to cut down the trees at some distance from the root, and thus a great deal of wood will be turned to a useful purpose, which would otherwise only encumber the ground. Every peasant, besides, by means of his axe alone, is able to construct such a pavement; and in Russia, hands are both plenty and cheap.

THE NEW ROYAL EXCHANGE.

In the Court of Common Council, on the 23rd ult., Mr. R. L. Jones brought up the report of the Royal Exchange Committee, which was as follows:—

"To the Right Hon. the Lord Mayor, Aldermen, and Commons of the city of London, in Common Council assembled.

"We whose names are hereunto subscribed of your committee in relation to the Royal Exchange and Gresham trusts, to whom on the 6th day of August, 1831, it was referred to carry into execution the Act of Parliament for improving the site of the Royal Exchange, in the city of London, and the avenues adjoining thereto, and to report our proceedings from time to time, do certify that we immediately proceeded to carry the provisions of the said act into execution, and directed several notices to be given to the several parties interested for the purchasing of their property required for the site of the new Exchange, and, having received the claims of the respective parties, we duly considered the same, and have great pleasure in being able to report that the whole of such claims, with two exceptions only, have been adjusted; and, for the further information of this Hon. Court, we have caused a statement to be hereunto annexed, setting forth the sums claimed, and the amounts paid or agreed to be paid, for the purchase of the several premises, including the loss and damage incurred by removal, together with the manner in which each claim was settled; all which we submit to the judgment of this Hon. Court. Dated this 23rd day of January, 1840.

"Richard L. Jones.	Edward Hickson.
B. Stubbing.	Henry J. Elmes.
W. Richardson.	Thomas Corney.
R. Obbard.	Thomas Burton.
James Frisby.	William Croucher."

The following is the statement alluded to:

Buildings purchased for the new Royal Exchange and avenues. Estimate 150,000*l.*, for which there were 56 claims.

42 cases claimed .	69,263	—Settled by committee at .	38,852
8 ditto for freeholds	107,981	—Referred to surveyors, and settled at . . .	94,136
4 cases claimed .	37,065	—Settled by verdicts at .	12,284
2 ditto not settled .	5,508		
	£219,817		£145,272

UNION WORKHOUSES.

Sir—On my road from Woolwich to London, the other day, I was much struck with the extensive appearance of the long-talked-of new workhouse for this union, which was to be the "*largest and best house*" under the commission. I walked over the whole establishment, and certainly it is the largest and best built house I have seen under the Poor Law Commissioners—the main building being upwards of 420 feet in length, by about 45 feet in depth—in height three floors (with basement under about half), and the ground floor well kept up, standing in an enclosed square acre (of lower buildings and work-sheds) about, 500 feet × 400 feet, with an old looking building in front (north), for board-room and offices; large range of buildings at back (south), for hospital, infirmary, fever wards, &c.; and work-sheds, wash-house, laundry, &c., at ends; upon the whole, presenting rather an imposing appearance—also an improved one—in comparison with the beggarly looking things erected by the Union generally. Mr. Browne, of Greenwich, is the architect, as in all the other houses (or some parties for him) fretted away the interior of this otherwise noble establishment with a great number of little, low, narrow rooms, called wards, which, were it not for a gallery on each floor, running the whole length of the building (near 420 feet), would be exceedingly inconvenient and unhealthy too—notwithstanding the great care that has been bestowed in the arrangement of the ventilation, the supply of water, and the drainage, to the whole establishment, which appears to me to have been very carefully studied and well executed—as well as the water-closets and other internal arrangements generally. Upon the suggestion and under the able superintendance of Mr. Leake, the Guardian Clerk of the Works, unto whom—one of the Guardians of the Board informed me—they were much indebted for his constant attention, great building tact and skill, and the full exercise of his first-rate mechanical and constructive capacities in their service: he is evidently a man very superiorly calculated to conduct large masses of work, as well as their detailed arrangement, and appears to be quite at home in this department of the business. The ground is on an inclination, with gravel bottom and good water; but the site stands awkwardly with the road, seeing the back of the front building before you see its front elevation, which might have been easily remedied, notwithstanding the depth of the ground; however, considering the house is built for about 1150 inmates, at an expense of less than £24,000. It reflects infinite credit both on Mr. Browne who has had much trouble and opposition to contend with; Mr. Jay of London Wall, who has done himself credit in the execution; the Board of Guardians for their spirit in giving an impetus to the large house yet to be built, and all parties concerned in the erection of those truly National Establishments. I would have given you a detailed account but time presses on me, so beg the insertion of this brief notice.

M. N. O.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

GEOLOGICAL SOCIETY.

The first meeting of this society for the session was held on Wednesday evening, the 6th November.

Rev. Professor Buckland, D.D., President, in the chair.

The following communications were read:

A notice of Showers of Ashes which fell on board the Roxburgh, off the Cape de Verd islands, in February last, by the Rev. W. B. Clarke.

On Tuesday, February 4th, the latitude of the ship at noon was 14 deg. 31 min. north, longitude 25 deg. 16 min. west. The sky was overcast, and the weather thick and insufferably oppressive, though the thermometer was only 72. At 3 p. m. the wind suddenly lulled into a calm, then rose from he south-west, accompanied by rain, and the air appeared to be filled with dust, which affected the eyes of the passengers and crew. At noon, on the 5th of February, the latitude of the *Roxburgh* was 12 deg. 36 min. north, longitude 24 deg. 13 min. west; the thermometer stood at 72, and the barometer at 30—the height which it had maintained during the voyage from England. The volcanic island of Fogo, one of the Cape de Verds, was about forty-five miles distant. The weather was clear and fine, but the sails were found to be covered with an impalpable reddish-brown powder, which Mr. Clarke states resembled many of the varieties of ashes ejected from Vesuvius, and evidently was not sand blown from the African deserts. The author also mentions the following instances of similar phenomena, chiefly on the authority of the officers of the *Roxburgh*. In June, 1822, the ship *Kingston*, of Bristol, bound to Jamaica, while passing near Fogo, had her sails covered with a similar brownish powder, which, it is said, smelt strongly of sulphur. In the latitude of the Canaries, and longitude 35 deg. west, showers of ashes have been noticed two or three times. At Bombay, dust, on one occasion, fell on the decks of the vessels to the depth of an inch, and it was supposed to have been blown from Arabia. In January, 1838, dust was noticed by the crew of a ship navigating the China Sea, and at a considerable distance from the Bashee islands, one of which had been previously seen in eruption. In 1812 ashes fell on the deck of a packet bound to the Brazils, and when 1000 miles from land.

A letter from Mr. Caldclough, dated Santiago de Chili, February 18th, 1839, containing the declaration of the master and part of the crew of the Chilian brig, *Thily*, of the discovery during the evening of the 12th of February, of three volcanic islands about thirty leagues to the east of Juan Fernandez. The island which was first noticed, appeared, at the time of its discovery, to be rising out of the sea. It afterwards divided into two pyramids, which crumbled away, but their base remained above the level of a violent surge, and in the course of the same evening, the height of the island was, for a time, again considerably increased. The other two volcanic islets bore further southwards. During the night the crew of the *Thily* noticed, at intervals, a light in the same direction.

A letter addressed to Mr. Lyell, by Mr. Buddle, of Newcastle, *On Depressions produced on the Surface of the Ground by the Excavations of Beds of Coal.*

The effects described in this paper are stated to depend on the four following conditions:—

1. The depth of the seam of coal below the surface.
2. The thickness of the seam.
3. The nature of the strata between the seam of coal and the surface.
4. Whether the pillars of coal are wholly or partially removed.

If the depth from the surface does not exceed thirty fathoms, and sandstone forms the greater part of the mass overlying the seam, the subsidence is nearly, if not quite, equal to the thickness of the coal removed; but if "metal stone" or shale constitute the bulk of the beds, the hollow produced by the settling of strata is less. This rule, depending on the nature of the intervening mass, is said to be maintained at all depths. Of the proportional effect produced on the surface, Mr. Buddle has not been able to obtain any accurate information—the amount depending on the four conditions enumerated above; but the depth of the depression depends less on the thickness of the seam than on its entire removal. In the Newcastle pits, where large pillars of coal are left in the first instance, and when these are subsequently removed, blocks or "stooks" of considerable strength are suffered to remain, for the purpose of protecting the colliers from the exfoliation of the roof, the sinking of the superincumbent mass is retarded, and several years sometimes elapse before the excavation is completely closed, or the overlying strata are finally settled down. In the Yorkshire system, by which all the coal, with the exception of small temporary pillars, is removed in the first instance, the roof being supported by wooden presses and stone pillars, the overlying strata subside immediately after the coal is removed.

It is only where water occurs on the surface, or a railway traverses a coal-field, that the amount of depression can be accurately ascertained. In one instance, the removal of a bed of coal six feet thick, one-fourth having been left in "stooks," the depth being 100 fathoms, and the overlying strata principally sandstone, a pond of water accumulated to the depth of rather more than three feet, by the settling of the strata. In another instance, where a railway crossed a district from beneath which three beds of coal had been successively removed, it had been found necessary to restore the level of the railway three times. The aggregate thickness of the seams of coal was nearly fifteen feet, and the depth of the lowest 107 fathoms, of the highest seventy-three, and the mass of the overlying strata consisted of shale. The extent of each settlement was not measured, but the total was 5 feet 6 inches, and this comparatively small amount Mr. Buddle explains by the railway passing near one end of the excavated tract. A still higher seam is now in progress of being worked, and it affords an excellent opportunity for ascertaining the effects produced by the pressure of the superincumbent mass. Innumerable vertical cracks pass through the seam, as well as the pavement and roof, or the beds immediately above and below it, but they are perfectly close except around the margin of the settlement. Along this line the seam is splintered, the pavement and roof are fissured and bent down, and the cracks are frequently open. Within the area of the settlement, the pavement, on the contrary, is as smooth as if it had not been disturbed, the cracks are close, and the coal is not splintered, but rendered tougher, or, in the language of the colliers, more "woody." This effect Mr. Buddle ascribes to the escape of gas by the cracks, and the same changes are sometimes produced by other causes, when the coal is said to be winded.

KING'S COLLEGE, LONDON.

Department of Civil Engineering and Science applied to the Arts and Manufactures.

Regulations in respect to Certificates.

1. The certificates of the second and third years will be of two forms—ordinary certificates, and certificates of honour.

2. No certificate, whether ordinary or of honour, will be granted, which, among the signatures affixed to it, does not include those of the professors of mathematics, mechanics, and chemistry.

3. A certificate of the second year will be necessary to obtaining one in the third.

4. Any student to whom a certificate shall have been refused at the Midsummer examination of any year, may apply for it at the examination of the following Christmas.

5. Every student, desirous of obtaining a certificate in science applied to the arts and manufactures, will be required to present to the examiners the detailed description of some process of manufacturing art, accompanied by the drawings necessary to the explanation of it. This exercise is to bear a certificate of approval from the lecturer on manufacturing art and machinery; and the subject of it is to be appointed by him at least three months before the day of examination.

The certificate of honour will be granted only when this exercise shall have been approved by the lecturer, as the exercise of a candidate for that certificate.

6. Every student applying for a certificate in civil engineering, whether of the first or second years, will be required to present to the examiners finished drawings of the plan, elevation, and section of a machine, made under the eye of the teacher of drawing, and bearing his certificate of approval.

For the certificate of the third year these drawings are to be accompanied by others, showing the details of the machine, drawn in isometrical projection, or in common perspective.

For the certificate of honour in the third year, each candidate will be required to produce, in addition to the above, the geometrical constructions of at least six problems in descriptive geometry.

1. On the intersections of surfaces.
2. On tangent planes.
3. On developable surfaces.
4. On projections of the circles of the sphere.

7. The diploma of associate in the department of civil engineering and science applied to the arts and manufactures, will be granted to such students only as shall have received the certificate of the third year.

8. Only such students as may have received certificates of honour in the third year will be admitted candidates for the diploma of associate of the first class.

9. The examination for the diploma of associate of the first class, will be held at the Christmas which follows the examination of the third year. Every candidate for the diploma of associate of the first class, will be required to present to the examiners, in writing, on the day of examination, the original project of some public work or mechanical contrivance or process of manufacturing art, accompanied by the calculations, drawings, and descriptions necessary to its actual execution, to be specially approved by the lecturer on mechanical art and machinery as the exercise of a candidate for the diploma of associate of the first class, and to bear his certificate to that effect.

ROYAL SOCIETY.

Dec. 12.—Major SABINE, V. P., in the Chair. G. L. Roupell, M. D., was elected a fellow. The following papers were read:—

1. "*On the nerves of the Gravid Uterus,*" by R. Lee, M.D.

2. "*Observations made at the Cape of Good Hope, in the year* 1838, *with Bradley's Zenith Sector, for the verification of the Amplitude of the Abbé de la Caille's Arc of the Meridian.*" By T. Maclear, Esq., communicated by Sir John Barrow, Bart.

The author gives an account of the precautions taken in putting together the different parts of the zenith sector, which he received on the 9th of December, 1837, in erecting it in the central room of the Royal Observatory, at the Cape of Good Hope, and in afterwards transferring it to the southern station of La Caille, in Cape Town. He then proceeds to describe La Caille's observatory, and the particular circumstances of its locality, with relation to the object in view—namely, to determine the influence of Table Mountain on the direction of the plumb line. He next relates his progress to Klyp Fonteyn, where he arrived on the 28th of March, 1838; and describes the operations resorted to for erecting the sector at that place. He then enters into the details of observations made at different stations, and especially with comparative observations at the summit and foot of the mountain of Pequet Berg. The instrument was, lastly, conveyed back to Cape Town, and again examined, and the observations made with it repeated. The reduction of the labours occupies the remainder of the paper; and, in conclusion, the author remarks, that, although these labours have not altogether cleared up the anomaly of La Caille's arc, yet they show that great credit is due to that distinguished astronomer, who, with imperfect means, and at the period in which he lived, arrived at a result derived from sixteen stars, almost identical with that from 1139 observations on forty stars, made with a celebrated and powerful instrument.

Dec. 19.—Major SABINE, V.P., in the Chair.

Henry Drummond, Esq., of Albany Park, Surrey, was elected a Fellow.

A paper was read, entitled "*An Account of Experiments made with the view of ascertaining the possibility of obtaining a spark* before *the circuit of the Voltaic Battery is completed.*" By J. P. Gassiot, Esq.

ROYAL INSTITUTION OF BRITISH ARCHITECTS.

At an ordinary General Meeting of the members, held on Monday December 16th, 1839, GEORGE BASEVI, Jun. V. P., in the Chair, numerous donations were announced as having been received since the last meeting.

Mr. Cottam delivered a discourse on the manufacture of bricks by machinery, illustrated by models, and drawings of the Marquis of Tweeddale's machines for making of bricks and tiles.

January 6.—THOMAS CHAWNER, Fellow, in the Chair.

The following gentlemen were elected: as Fellow, James Penythorne, Architect, of 2, Queen Square, Westminster; as Associate, James Bell, of Wandsworth.

Mr. Donaldson read a paper on the life of Ammanate, Architect of Florence.

January 20.—EDWARD BLORE, V. P., in the Chair.

The following gentlemen were elected: as Fellow, John Crake, Architect, of Old Quebec Street; Associate, F. Ashton, of No. 2, Pelham Crescent.

Several donations were announced as having been received, among which was a donation of 10*l.*, by Thomas Chawner, Esq., Fellow.

A highly interesting paper of deep research was read by Edward I'Anson, Jun., on the Temple of Victory, Apteros, at Athens, accompanied by drawings illustrative of its state of restoration in the Spring of 1836.

Mr. Donaldson read a paper by Herr Hallemann, Architect, from Hanover, on the History of Grecian and Russian Ecclesiastical Architecture, illustrated by examples, and an original design

MEETINGS OF SOCIETIES IN FEBRUARY.

Institution of Civil Engineers, 25, Great George Street, every Tuesday at 8.

Royal Institute of British Architects, 16, Grosvenor Street, Monday 3rd and 17th, at 8.

Architectural Society, Lincoln's Inn Fields, Tuesday the 25th, at 8.

Society of Arts, Adelphi, every Wednesday at half-past 7.

Royal Society . } Somerset House, every Tuesday at 8.
Society of Antiquaries }

PROCEEDINGS IN PARLIAMENT.

HOUSE OF COMMONS.

January 17. *Petitions for Bills presented.*—Arbroath and Forfar Railway; Sheffield and Rotherham Railway Act Amendment; Lancaster and Preston Railway Act Amendment; Chester and Birkenhead Railway; Taff Vale Railway; North Union Railway.

Jan. 20.—Edinburgh and Glasgow Railway.

Jan. 21.—Great Level of the Wash Inclosure.

Jan. 22. *Petitions referred to the Select Committee on Petitions for Private Bills.*—Arbroath and Forfar Railway; Sheffield and Rotherham Railway Act Amendment, referred to Select Committee on Petitions for Private Bills; Lancaster and Preston Railway Act Amendment, petition; Chester and Birkenhead Railway; Taff Vale Railway; North Union Railway; Edinburgh and Glasgow Railway; Glasgow, Paisley, Kilmarnock, and Ayr Railway. Railway Communication.—Select Committee appointed, "to inquire into the state of communication by railways, and to report their observations thereupon to the House:" Mr. Labouchere, Sir Robert Peel, Lord Granville Somerset, Mr. Thorneley, Lord Sandon, Mr. Loch, Mr. Freshfield, Sir John Guest, Lord Stanley, Mr. Greene, Sir Harry Verney, Mr. Henry Baring, Sir James Graham, Lord Seymour, Mr. Easthorpe, Mr. Emerson Tennent, and Mr. French:—Power to send for persons, papers, and records five to be the quorum.

STEAM NAVIGATION.

Steam Navigation.—We are much gratified to perceive the improved condition of seamen generally, and to hear congratulatory accounts on all sides respecting this desirable event. The infusion of young blood of the right quality, in the persons of upwards of twenty-four thousand apprentices, within the last five years, has had a marked effect upon the mass; for some thousands of these having completed their apprenticeship, are now become active able seamen. The number of apprentices reared in steam-vessels—(the General Steam Navigation alone maintain upwards of fifty, principally selected from the Naval School's at Greenwich)—will become a most valuable class of men; and we have heard that the highly respectable firm of Seward and Co., so celebrated for their success in the manufacture and improvement of steam-engines, have now upwards of three hundred youths indentured as apprentices, with the view of their becoming engineers and assistant engineers in steam-vessels, and fully competent to repair any casualty in the engines that is practicable at sea, without the necessity for returning to port or laying up the vessel.—*Naval and Military Gazette.*

Improved Marine Engines.—A fine new iron steam boat, the property o Lord F. Egerton, or in other words of the Bridgewater Trust, was recently launched from the yard of Messrs. Page and Grantham. She was named the *Alice*, after Lord Francis Egerton's eldest daughter, is about 170 tons burden, old measurement, is neatly fitted up, and is a handsome lively looking boat on the water. With the whole of her machinery, fuel, &c. on board, her draft of water is only four feet six inches. She has two engines of 30 horse power each, made by Messrs. Devonport and Grimrod, of the Caledonian Foundry in this town, upon a novel and improved construction, their peculiarity consists in the fixing of the cylinders on an angle of 45 degrees in the form of a rectangle, with the hypothenuze at the base, so that they act as a stay and support to each other. No side levers *are required or counter balances*; and the working parts being fewer than in ordinary engines, they are less liable to derangement, and not so much exposed to *wear and tear*. These engines are exceedingly compact, and have realized all that was contemplated by the ingenious makers—ample power, ease in working, and great strength, combined with unusual lightness. At twelve on Saturday night several gentlemen proceeded in the vessel from the Clarence Dock on a short experimental trip on the river. New engines are necessarily stiff, and it requires some time to ascertain their proper adjustment. With all disadvantages, however, the *Alice* performed her work admirably, from the moment she left the dock. A very short trip only was intended on the first occasion; but the speed of the vessel was so satisfactory, and the gratification of all on board consequently so great, that she proceeded up the river a distance of 12 or 14 miles and back—accomplishing the trip "out and home" in about two hours. On her way up she beat several very powerful steamers, and on coming down successively headed two of the Runcorn packets in gallant style. The strokes of the engine averaged thirty-two per minute, but when at her full power they will make thirty-five.—*Liverpool Standard, Dec. 21.*

HALL'S REEFING PADDLES.

"The inventor is Mr. Hall, the ingenious deviser of the condenser which goes by his name. By a contrivance of the utmost simplicity, all the float-boards of both paddle-wheels of a steam-boat, or either of them, can at any time, or in any weather, be 'reefed' in a few minutes; or, in other words, the diameter of the paddle-wheels be reduced from their extreme size to any other diameter. The advantages which will follow this contrivance are well-known to all persons who have attended personally to steam navigation; but a few words on this point will perhaps not be unacceptable to those who may not have had opportunities of studying the subject afloat under varied circumstances.

Every one can understand that, when a steam-vessel is loaded with a heavy cargo, or has a full supply of coals on board, the paddle-wheels will be sunk to an inconvenient depth in the water, and that, in order to enable them to work with advantage, the float-boards require to be unscrewed and shifted nearer to the centre of the paddle-wheel—an operation of some trouble, and often requiring much time. This adjustment may, of course, be made at the beginning of a voyage, according to the draught of water, but it may become fully as necessary to shift the paddle-boards during the voyage, either farther out or farther in. If the vessel, for instance, by the expenditure of her coals, becomes lighter, the float-boards should be moved out; or, if a gale comes on a-head, they have to be moved in; which operations, if they have to be done in bad weather, are both tedious and difficult. So that any invention which shall give the power of shifting the float-boards easily and quietly, must be of great practical utility, especially on long voyages.

"It is well-known to those who have attended to the subject that no steam vessel can be said to work to the full extent of her power unless her engines make a given number of strokes in a given time—say in a minute; the elasticity of the steam being supposed to continue uniformly of a certain determinate strength. Now occasions constantly arise when, in consequence of the paddle-wheels being too deeply immersed, or that the sea is high, the float-boards are made to impinge on the surface at such an unfavourable angle, and again on leaving it, that a considerable portion of the power is lost in production of what is called back-water. The consequence is, that the paddle-wheel is virtually so over-loaded, that the steam though generated of the proper degree of elasticity is not adequate to turn them round the given number of times. When this happens, as the engine does not make the number of strokes per minute which it ought to do when working at its maximum speed, one of two things must happen, either steam must be blown off and power wasted, or the fire must be lowered in order that no more steam may be generated than the engine, at its reduced number of strokes, can consume. In consequence of this state of things, it happens not unfrequently that vessels whose paddles are too deeply immersed, though carrying a high nominal power, are obliged to work with a power really much inferior.—*United Service Journal.*

The Great Western.—We are happy in being able to say that the examination of this noble vessel since her laying up shows that there is neither spot nor blemish in her, that she does not require caulking or coppering, beyond a few sheets to replace those which have been rubbed off by the coal vessels, or have been removed for the purpose of a thorough examination. All the parts of the engines which are not fixtures have been taken out and thoroughly examined, and are now in progress of replacement. The plan of the directors is to overhaul her completely once a year; and we should say after 35,000 nautical miles steaming per annum, an almost indispensable one, if confidence is to be maintained with the public. We understand that the poop deck is to be lengthened 15 feet; and that the whole of the officers, engineers, stokers, and servants, whose berths below were a great inconvenience and annoyance to the fore cabin passengers, are to be accommodated on deck; also that the fares are to be all equal in the fore and after accommodation, the fore state rooms having been considerably enlarged. She will sail on the 20th of February.—*Bristol Mirror.*

The President Steam-ship.—On Sunday the 5th ult., the Royal William steamer, on her passage from London to Plymouth, fell in with, off the Start, the magnificent steamer President, on her voyage from London to Liverpool, (to take in her machinery), in quite an unmanageable state, having rolled away her foremast, maintopmast, &c. The Royal William took her in tow, and brought her into the Sound during Sunday night. On Tuesday she was towed up to the dockyard by Her Majesty's steamer Carron, and the same evening one of the directors of the British and American Navigation Company, for whose service she is built, arrived from London to superintend her refitment.—*Plymouth Journal.*

The Armed Steamer, Nemesis.—There is now lying in the Half-tide Basin of the Clarence Docks, Greenock, a very beautiful iron steamer, constructed by Mr. John Laird, of North Birkenhead, bearing the above name. She is fitted up with one engine of 120 horse power, and armed with two 32-pound carronades, the one fore and the other aft, which move on solid swivel carriages. Her draught of water is under four feet. Her crew will consist of 40 men. She will, it is said, clear out for Brazil, but her ultimate destination is conjectured to be to the Eastern and Chinese seas. On Monday last she made an excursion as far as the Floating Light, for the purpose of trying her machinery, which was found to work admirably.—*Edinburgh Observer.*

Leith Harbour and Docks.—Messrs. Walker and Cubitt have given in their report, and the Treasury have decided on adopting Mr. Walker's plan.

PROGRESS OF RAILWAYS.

Sheffield and Manchester Railway.—Mr. Vignoles has resigned his office as engineer-in-chief, and Mr. Locke has been appointed to succeed him. The directors, we understand, intend pushing forward with all possible vigour the works between Glossop and the Manchester terminus, so as to be able to open in the first instance through that very populous and productive district. The works at the summit tunnel are making very satisfactory progress.—*Railway Times.*

Hull and Selby Railway.—We understand that Mr. Walker, the company's chief engineer, has been in Hull this week, and after examining the various works on the line, has reported very favourably as to the progress which is being made in them; the bridges over the rivers Ouse and Derwent are in an advanced state of forwardness, and will both be completed in a few weeks; nearly the whole of the line is ballasted, and several miles of the permanent single way, on longitudinal bearers and cross sleepers, are already laid; large quantities of these are being constantly forwarded to the various portions of the line. The depôt and other buildings at Selby are in a very advanced state; this is also the case with those at the Hull terminus; and, although the past season has been a most unfavourable one for all railway works, it is still hoped that this undertaking will be ready to be opened for the whole length about Midsummer next. With respect to finances, we understand that the whole of the amount to be taken up on loan has been obtained without advertising, and the last call, notwithstanding the pressure upon the money market, has been remarkably well paid. We may congratulate our townsmen especially, and the inhabitants of the manufacturing districts of Yorkshire and Lancashire generally, on the prospect of speedily being enabled, by means of the Hull and Selby Railway, (connected as it is with the Leeds and Selby, the York and North Midland Counties, Manchester and Leeds, Manchester and Liverpool, Grand Junction, and London and Birmingham Railways,) to travel by this cheap, safe, and expeditious mode to all the principal towns in the kingdom. We are happy to learn that the price of shares in the Hull and Selby Railway is rapidly advancing in the market, and that before the opening of the line, as above stated, they are likely to be at par.—*Eastern Counties Herald.*

Edinburgh and Glasgow Railway.—We are glad to learn from a correspondent who lately visited the Edinburgh and Glasgow Railway works, now in progress, especially those through the Almond Valley, about eight miles from Edinburgh, under contract by Messrs. John Gibb and Son, on which there is one bridge of thirty-six arches, of fifty feet span each, besides numerous smaller bridges, extensive earth-cuttings, &c., that these gentlemen contemplate employing on these works, early in the spring, a vast number of masons, quarriers, earth-workers, and waggon-drivers. We have no doubt that this will be good news to many, especially as trade in the manufacturing districts is in such a depressed state.—*Aberdeen Journal.*

Dundee and Arbroath Railway.—This great public undertaking is nearly completed, the embankment has been formed up to the Gas Work, and in the course of two or three weeks the embankments from the east and west will have nearly met. As an arrangement has now, we believe been made with the Harbour Trustees, the public will soon have the full benefit of this conveyance from Trades-lane to Arbroath, and the inconvenience and trouble occasioned by the omnibuses will be avoided. It is said there will be a grand opening on the completion of the line; and it is not unlikely that Lord Panmure, who has all along manifested the greatest interest in the work, will be present. There are four vessels in a dangerous situation, as they will be closed in unless they get launched at the next stream tide; the parties will have themselves to blame if such an event takes place, the vessels being all ready for launching.—*Dundee Courier.*

Maryport and Carlisle Railway.—At a meeting of the directors of this railway, held on Saturday last, there was a report upon the state of the works, &c., by John Blackmore, Esq., lately appointed engineer to the company. It appears that about seven miles of the railway will be ready for the carriage of coal and lime about the first week in April next. Arrangements were entered into with parties desirous of taking coals along the line for shipment at Maryport, from which it is evident that an income will at once be realized sufficient to pay ten per cent. upon the amount of capital that will then have been expended, and this without taking into account any other source of traffic or the increase of coal that will undoubtedly take place. While upon this subject we beg leave to warn those shareholders, particularly the distant ones, who have not the opportunity of gaining correct information about the proceedings of the company, against a practice that has lately become too common of parties who calumniate and depreciate the value of property of the above description for the purpose of getting shares from the timid or needy at very reduced prices. The engineer has commenced the necessary surveys for setting out the work on the remaining twenty miles, from Carlisle to Aspatria, and for ending the agreements to be made for the land required. —*Carlisle Patriot*, January 11.

Great North of England Railway.—Two first-class railway carriages have just been placed on the line of the Great North of England Railway, at the Darlington Station. The carriages, which are from the manufactory of Mr. C Burnup, of this town, are of the most splendid description, and combine every improvement that has hitherto been introduced. The interior arrangements are exceedingly comfortable, and the exterior decorations are beautifully executed, each door panel bearing the united arms of Newcastle, Durham and York, supported by the Northern Eagle. The carriages have since been inspected by several of the directors and engineers, who all express their entire satisfaction and admiration of their beauty and useful construction. It is expected that the portion of the line between Darlington and York, will be opened to the public in the course of the ensuing summer.—*Newcastle Journal.*

London and Birmingham Railway.—Saturday evening a considerable subsidence took place at the Bisworth embankment, half way between the station and the bridge over the canal. The earth having become thoroughly saturated by the late rains, gave way at the bottom, and the surface in consequence gradually sunk, at one point several feet. Since then it has continued to subside at the rate of about a foot an hour, and on one occasion between two and six in the morning, when the men ceased to work, it sunk eight feet. A large force of men were collected the moment the slip was discovered, and employed day and night replacing the soil that had given way with ballast, the trains in the mean time passing slowly over the spot. The gap is always filled up by the arrival of a train, and the precautions taken are such as to do away with all idea of danger. The ballast is brought partly from Bugbrook, but chiefly from Hillmorton, about 16 miles distant.—*Northampton Mercury*, January 11.

Railway Speed.—Last week we referred to the facilities afforded by the Great Western Railway in the conveyance of newspaper expresses from Monmouth, and noticed the great rate of speed at which the special trains on these occasions had run. The *Dispatch* (Sunday paper), in alluding to one of its own expresses, states that the *Atlas* engine performed the first *ten* miles in *seven* minutes, and that it the engineer had not been compelled to slacken his speed in consequence of a train having started a short time previously, the whole distance of 31 miles could easily have been accomplished in 25 minutes. This is at the rate of 74 miles an hour!—*Railway Times*, Jan. 18.

London and South-Western Railway.—The whole of the rails being now laid down between the temporary terminus at Northam and the terminus on the Marsh, the engine has several times been along the whole line. The building on the Marsh is also completed, and rising, as it does, higher than any of the adjacent edifices, forms a very conspicuous object, especially when viewed from the water. Workmen are actively engaged on the yet unfinished part of the line between Winchester and Basingstoke, and though the late unseasonable weather has impeded their progress in a great degree, little doubt is entertained of their completing it by the 1st of May, when the good folks of Southampton will be enabled to reach the metropolis in three hours.—*Southampton paper.*

Morecombe Bay.—By the intended enclosure of Morecombe Bay and the Duddon Sands, 52,000 acres of land will be reclaimed, which will form two of the most beautiful valleys in the lake district of 83 square miles. The sands, being composed almost entirely of calcareous matter washed from the surrounding limestone, are capable of being formed into the most fertile soil for agriculture. The land proposed to be reclaimed, will form an area half the size of Rutlandshire, and, calculating one individual for two acres, will accommodate a population of 26,000, being about half the number of the present population of the counties of Huntingdon and Westmoreland, and, 5,000 more than that of Rutland. It would be about equal in population and extent to Lonsdale North, which is a peninsula lying between the two bays of Morecombe and the Duddon, on which stand the ancient ruins of Furness Abbey, and is also a rich agricultural and manufacturing district, abounding with slate, iron, and copper mines. By the reclaimed land being added to it, Lonsdale North would form one of the most pleasant and compact counties in the kingdom.—*Lancaster Guardian.*

Maidenhead Bridge, on the Great Western Railway.—A correspondent informs us that during the hurricane of Friday, the 24th ult., the timber centerings of the bridge, which had been left standing under the arches for some time past as a precautionary measure, were completely carried away by the force of the wind and the timbers scattered about the river in all directions. This event will now decide whether the bridge will stand or not without the aid of the centres, it is very evident that the brickwork of the arches was not supported by the centres, as some have supposed, for if that had been the case, they could not have been so easily carried away.

NEW CHURCHES, &c.

Blackheath.—A new church intended for the accommodation of about 1100 persons is in progress of erection at Lee, near Blackheath. It is designed in the first pointed or early English style, adopting as a model for the component parts of the exterior, the Lady Chapel of Salisbury Cathedral. At the west end placed centrally rises a bold tower, which is surmounted by an octagonal belfry and spire, reaching to the height of 130 feet. The interior is divided into a nave and aisles by two ranges of clustered pillars, from which spring molded arches supporting the roof, the latter is of a triplex form the central division rising from nearly the same level as the sides, so that there is no clerestory. The ceiling is to be finished in a style posterior to that of the building generally, it will consist of plane surfaces divided into principal compartments by hammer beams or arched ribs, and these compartments subdivided into panels by smaller ribs, having bosses at their intersections. A gallery is to be placed at the west end of the church, occupying lengthwise its entire width, and one bay or intercolumniation in depth. The whole area of the building has been excavated and a vaulted crypt formed, which is to be divided into numerous compartments, to be appropriated as family vaults. The external dressings throughout, together with the whole of the belfry and spire, as well as the pillars and arches of the interior are executed in stone.

Wolverhampton.—The erection of the new church in Horsley Fields will be commenced as soon as the necessary legal forms are completed. The building, as before stated, will be in the gothic style, and according to the design sent in by Mr. Harvey Eginton, of Worcester. Twenty-five plans were sent in, but several of them were unavoidably rejected on account of the cost of the proposed buildings exceeding the funds at the disposal of the committee. The structure will be eighty feet long and fifty-six feet wide, and is to be surmounted by a tower eighty-four feet high, in the style of the time of Henry VII. It will contain sittings for 1,200 persons, one-third of which are to be free.—*Wolverhampton Chronicle.*

Calcutta.—The Bishop of Calcutta has proposed building a cathedral church at Calcutta, in the Gothic style of architecture; unencumbered with galleries; with an ample chancel or choir; with north and south transepts or entrances; and capable of seating about 800 or 1,000 persons, its dimensions being probably somewhere about 180 or 200 feet, by 55 or 60; and 50 or 60 feet in height. In correspondence with this necessary magnitude of the body of the edifice, it is designed that the exterior of the building should bear some relation in its architectural character to the interior; and that an appropriate spire, somewhere about 200 feet in height from the ground, should be added, to give the whole a becoming and customary ecclesiastical aspect. It was, indeed, the unavoidable extent of a building which could at all meet the actual wants of the case in a climate like Bengal that first suggested the idea of erecting it in an open and beautiful spot, and of such a style of architecture as to form a prominent object from every point of view on the esplanade, within the fine panorama of Calcutta, and thus constitute the greatest ornament of what has not been unfitly termed the City of Palaces. And it was thought there are few who would not willingly make an additional effort—if we once determine to build a new and large church—to give it all the advantages which the progress made of late years in sacred architecture can secure, so as to render it fitting to be the first Protestant cathedral erected to the honour of God in India.

Liverpool.—The first stone of a new church, to be called after St. Barnabas, to be erected on a plot of land between Parliament-street and Greenland-street, a few yards from the Queen's Dock, was laid on Tuesday, December 17. St. Barnabas' church will be a handsome structure, in the early English or Lancet style, and a decided ornament to that part of the town. The principal elevation will be towards Parliament-street, and from the centre there will rise a beautiful tower and spire to the height of 135 feet. The former will be finished with a pierced battlement on four sides and shafts with pinnacles at the angles. The whole will be faced with red stone in large courses. The interior will correspond with the general style. It will have a nave separated from the aisles by moulded stone piers and arches, supporting a clear story in which there will be windows of three lights. The ceiling is to be ribbed and pannelled, and the ribs will be painted to resemble oak. It is intended to furnish 1200 sittings; on the ground floor there will be 471 sittings and 236 free sittings, in the gallery 346 sittings and 147 free. making 1200, of which 383 will be dedicated to the use of the poor for ever. The cost will be upwards of £1800. The architects are Messrs. Arthur and George Williams, of No. 2, Tarleton-street, and Mr. William Morrison, of Toxteth-park, is the contractor.—*Liverpool Standard.*

The new church at Boughton, in this county, which has been built upon a wet loose soil, has been some time subsiding, but the late rains have so impaired the foundation that the tower at the western extremity first sunk, and then fell to the ground, and the other appears also to be sinking very fast. Of course the whole presents a very ruinous appearance.—*Kent Herald.*

GEOLOGY.

Geology in Devon.—Dr. Buckland and Mr. Conybeare have both hastened to visit the late landslip on the coast of Devon, which, we understand, offers some very curious phenomena to the geologist both inland and out at sea, where, at a considerable distance from the shore, a new solid ridge has been thrown up by this convulsion of nature.—*Naval and Military Gazette.*

The Lagoons.—A Vienna correspondent of a Paris paper states that accounts had been received from Venice of the disappearance of a little island of the Lagoons in the waves of the Adriatic. 12 persons who were on it having been buried in the waters when the island was overwhelmed. The Archduke, Viceroy of the kingdom of Venetian Lombardy, had gone from Venice to Padua to inspect the ravages caused by the late inundations, and the clergy of Milan and Cremona were exerting themselves to relieve the sufferers.

Earthquake at San Salvador.—We have been favoured with the following extract of a letter from San Salvador, dated the 5th of October, 1839:—"On the 1st instant, at 2 a.m., we experienced a strong shock of an earthquake, and at 3 a.m., an hour after, a concussion which has nearly destroyed the town. The shocks continue, and yesterday we had 15 tolerably smart shocks. Many people have left the place, and I fancy the Government will remove to Cojutepeque, as this town is not safe. The evil is under our feet; for at places five or six miles off nothing has occurred. The houses are nearly unroofed, and the walls are so tottering that we all sleep in the court-yard or the great square, under hide coverings, which is pleasant enough in the rainy season, and sit in the day time in the corridors ready for a start into the yard, as it will not do to wait a moment when the shock comes."

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 1ST TO 28TH JANUARY, 1840.

John Leo Nicolas, of the parish of Clifton, Bristol, Gentleman, for "*certain improvements in the method of constructing and propelling carriages on railways or common roads, and through fields for agricultural purposes.*"—Sealed, January 1; six months to specify.

Samuel Lawson, of Leeds, and John Lawson, of the same place, Engineers, and Co-partners, for "*improvements in machinery for spinning, doubling, and twisting flax, wool, silk, cotton, and other fibrous substances.*" Communicated by a foreigner residing abroad.—January 2; six months.

Charles Greenway, of Douglas, in the Isle of Man, Esq., for "*certain improvements in reducing friction in wheels of carriages, which improvements are also applicable to bearings and journals of machinery.*"—January 3; six months.

John Francois Victor Fabien, of King William Street, in the city of London, Gentleman, for "*improvements in pumps.*"—January 7; six months.

David Low, of Adam's Court, Old Broad Street, Merchant, for "*improvements in machinery for crushing, preparing, and combing flax, hemp, phormium tenax, and other fibrous substances.*" Communicated by a foreigner residing abroad.—January 7; six months.

Moses Poole, of Lincoln's Inn, Gentleman, for "*improvements in obtaining power.*" Communicated by a foreigner residing abroad.—January 7; six months.

John Ridgway, of Cauldon Place, Stafford, China Manufacturer, for "*an improvement in the moulds used in the manufacture of earthenware, porcelain, and other similar substances, whereby such moulds are rendered more durable.*"—January 11; six months.

John Ridgway, of Cauldon Place, Stafford, China Manufacturer, and George Wall, the younger, of the same place, Gentleman, for "*certain improvements in the manufacture of china and earthenware, and in the apparatus or machinery applicable thereto.*—January 11; six months.

John Ridgway, of Cauldon Place, Stafford, China Manufacturer, and George Wall, the younger, of the same place, Gentleman, for "*certain improvements in the mode of preparing bats of earthenware and porcelain clays, and forming or shaping them into articles of earthenware and porcelain, and in the machinery or apparatus applicable thereto.*"—January 11; six months.

Robert Montgomery, of Johnstone, in the county of Renfrew, Gentleman, for "*an improvement or improvements in spinning machinery, applicable to mules, jennies, slubbers, and other similar mechanism.*"—January 11; six months.

Christopher Edward Dampier, of Ware, Attorney-at-law, for "*an improved weighing machine.*"—January 14; four months.

Hezekiah Marshall, of the city of Canterbury, Architect, for "*improvements in window sashes and frames, and in the fastening of window sashes.*"—January 14; six months.

Arthur Eldred Walker, of Melton Street, Euston Square, Engineer, for "*improvements in engraving by machinery.*"—January 14; six months.

Charles Wheatstone, of Conduit Street, Hanover Square, Esq., and William Fothergill Cooke, of Sussex Cottage, Slough, Esq., for "*improvements in giving signals and sounding alarms at distant places, by means of electric currents.*—January 21; six months.

Samuel Brown, of Finsbury Pavement, Civil Engineer, for "*improvements in making casks and vessels, of or from iron, and other metals.*—January 21; six months.

Joseph Rock Cooper, of Birmingham, Gun Maker, for "*improvements in fire-arms, and in the balls to be used therewith.*—January 21; six months.

William Stone, of Winsley, Gentleman, for "*improvements in the manufacture of wine.*"—January 21; six months.

James Hall, of Glasgow, Upholsterer, for "*improvements in beds, mattrasses, and apparatus applicable to bedsteads, couches, and chairs.*—January 21; six months.

Arthur Howe Holdsworth, of Brookhill, Devon, Esquire, for "*improvements in preserving wood from decay.*"—January 21; six months.

William Coltman, of Leicester, Frame Smith, and Joseph Wale, of the same place, Frame Smith, for "*improvements in machinery employed in making frame-work, knitting, or stocking fabrics.*"—January 21; six months.

Samuel Wilkes, of Darlston, Iron Founder, for "*improvements in the manufacture of hinges.*"—January 21; six months.

George Wilson, of Saint Martin's Court, Saint Martin's Lane, for "*an improved paper-cutting machine.*"—January 21; six months.

Charles Rowley, of Birmingham, Stamper and Piercer, and Benjamin Wakefield, of Bordesley, Machinist, for "*improved methods of cutting out, stamping, or forming, and piercing buttons, shells, and backs for buttons, washers, or other articles, from metal plate, with improved machinery and tools for those purposes.*—January 21; six months.

Edward Halliley, of Leeds, Cloth Manufacturer, for "*improvements in machinery for raising pile on woollen and other fabrics.*—January 21; six months.

William Hunt, of the Portugal Hotel, Fleet Street, London, Manufacturing Chemist, for "*improvements in the manufacture of potash and soda, and their carbonates.*"—January 21; six months.

Miles Berry, of Chancery Lane, Patent Agent, for "*certain improvements in the manufacture of prussiate of potash and prussiate of soda.*" Communicated by a foreigner residing abroad.—January 21; six months.

Jules Alphonse Simon de Gournay, of Bread Street, London, Gentleman, for "*improvements in the manufacture of horse-shoes.*" Communicated by a foreigner residing abroad.—January 21; six months.

George Clarke, of Manchester, Manufacturer, for "*certain improvements in the construction of looms for weaving.*"—January 21; six months.

Alexander Helt, of Gower Street, Bedford Square, Surgeon, for "*certain improvements in the arrangement and construction of fire-grates, or fire-places, applicable to various purposes.*"—January 23; six months.

James Bingham, of Sheffield, Manufacturer, and John Amory Boden, of the same place, Manufacturer, for "*certain improved compositions, which are made to resemble ivory, bone, horn, mother-o'-pearl, and other substances, applicable to the manufacture of handles of knives, forks, and razors, piano-forte keys, snuff-boxes, and various other articles.*"—January 25; six months.

James Smith, Junior, and Francis Smith, of Spital Works, near Chesterfield, Lace Manufacturers, for "*certain improvements in machinery for the manufacture of figured bobbin-net, or lace.*—January 28; six months.

Thomas Aitken, of Chadderton, Manufacturer, for "*certain improvements in the machinery or apparatus for drawing cotton and other fibrous substances.*"—January 28; six months.

William Pontifex, of Shoe Lane, in the city of London, Coppersmith, for "*an improvement in treating fluids containing colouring matter to obtain the colouring matter therefrom.*"—January 28; six months.

Henry Curzon, of the borough of Kidderminster, Machinist, for "*certain improvements in steam-engines.*"—January 28; six months.

John Whitehouse, of West Bromwich, in the county of Stafford, Iron Master, for "*improvements in preparing and rolling iron, and other metals, or metallic alloys, for the manufacture of certain articles of commerce.*"—January 28; six months.

William Mottershaw Forman, of Sheepshead, in the county of Leicester, Frame Smith, for "*certain improvements in stocking frames, and machinery used in frame-work knitting.*"—January 28; six months.

TO CORRESPONDENTS.

In consequence of the great advantages to correspondence by the universal introduction of the penny post throughout the United Kingdom, we hope that our readers will do us the favour to forward accounts of all new buildings, public works, new inventions and discoveries, reports of scientific meetings, new engines, steam boats, docks, canals, harbours, &c., if a tithe of our readers will only take the trouble to forward a dozen lines monthly, it will be the means of affording such a mass of information, that could not fail to be most valuable to the profession.

We thank our correspondent at Montreal for his letter, we think that he and his professional brethren might obtain the Journal in a far more direct manner, than through the circuitous and expensive channel of New York. We advise him to consult a respectable bookseller, or some agent who is in constant correspondence with England. We shall be happy to receive the information he proposes.

We feel particularly obliged to our correspondent Mr. W. R. Casey *of New York for his valuable contributions, we hope to have a continuation of them.*

A correspondent requests us to publish the description of the Epicycloidal motion for a steam engine which we stated was not new. We will, if we can find room, do so next month, or refer him to works and places where it may be seen. The last time we visited the Arsenal at Woolwich, we saw the motion applied to the working of a perpendicular saw for cutting timber.

R. W. T.'s *last letter we will answer next month. His former communication was received, we did not insert it as we were desirous of avoiding the insertion of any further articles on railway curves.*

Diogenes' *apparatus for stopping carriages on railways will appear next month, will* Diogenes *be so good as to inform us if it be the same apparatus as Thompson's alluded to in his paper in last month's Journal.*

I. Z.'s *drawing for a paddle wheel with reefing paddles, constructed by Boulton and Watt, in 1815, will appear next month.*

H. B.'s *syphon for a high pressure steam gauge we will notice if we can spare the room next month.*

We have this month made an alteration in the Journal by the introduction of engravings instead of wood cuts; this plan we shall occasionally adopt when the subjects for illustration are of a minute character. At the end of the year, when the numbers are bound up, the plates will be placed opposite to the letterpress referring to them.

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster, or to Mr. Groombridge, Panyer Alley, Paternoster Row: if by post, to be directed to the former place; if by parcel, to be directed to the nearest of the two places where the coach arrives at in London, as we are frequently put to the expence of one or two shillings for the* porterage only, *of a very small parcel.*

Books for review must be sent early in the month, communications on or before the 20th (if with wood-cuts, earlier), and advertisements on or before the 25th instant.

Improved Steam Engine with two Cranks

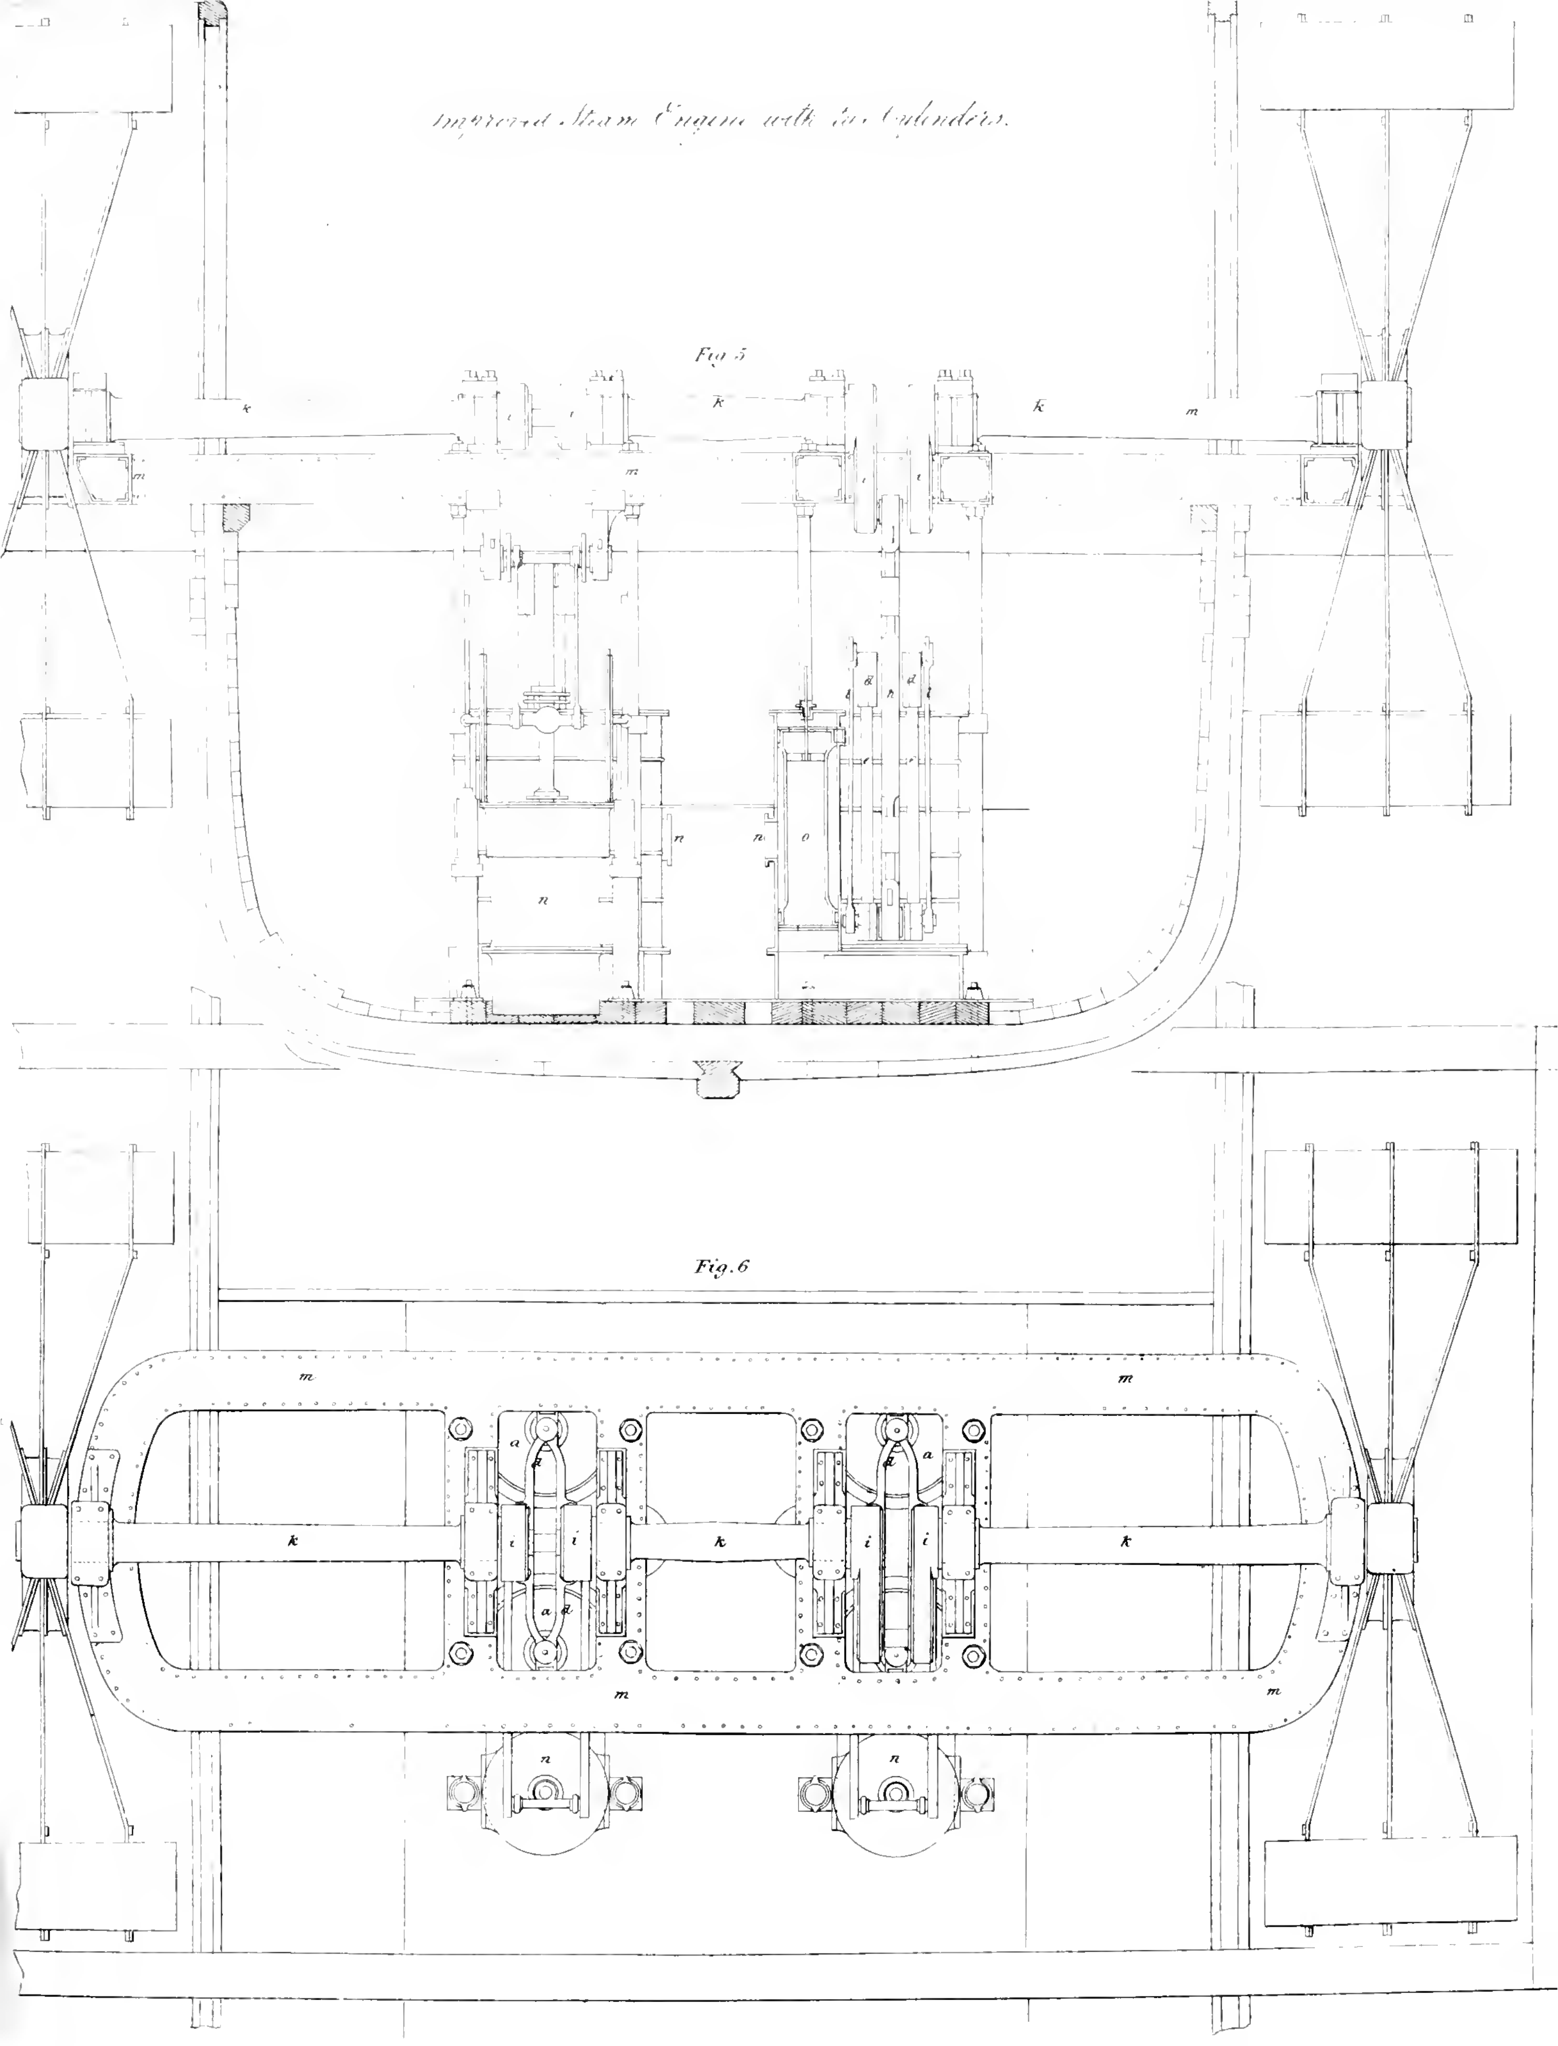
Improved Steam Engine with two Cylinders.



IMPROVEMENTS IN THE CONSTRUCTION OF MARINE STEAM ENGINES.

WHICH ARE PARTICULARLY APPLICABLE TO STEAM ENGINES OF THE LARGEST CLASS.

With two Engravings, Plates V and VI.

SPECIFICATION *of a Patent granted 7th May,* 1839, *to* JOSEPH MAUDSLEY *and* JOSHUA FIELD, *of the firm of Maudsley, Sons and Field, Engineers of Lambeth.*

THESE improvements in the construction of marine steam engines are particularly applicable to those of the larger class, and are designed principally for the purpose of producing and applying a greater amount of steam power, than has heretofore been available within a given space or area on shipboard. This is effected by different constructions, arrangements, and proportions, of the parts of low pressure engines, allowing a more perfect application of the expansive force of steam without increasing the weight of the whole machinery.

The first feature of these improvements consists in adapting two steam cylinders to one engine, in such a way that the steam shall act simultaneously upon both pistons, in order that they may be made to rise or fall together, the piston-rod of each being attached to one horizontal cross-head, and thereby the combined action of both pistons applied to one crank of the paddle-shaft.

The second feature of these improvements applies more particularly to engines for river navigation, and consists in the adaptation of a piston with two rods, working in a steam cylinder of large area, both piston-rods being connected to one cross-head above, which gives motion to the crank below it, by a single connecting rod.

The third feature of these improvements consists of a method of adjusting the expansion valves of combined engines, by which the period for shutting off the steam at any part of the stroke may be regulated in both engines at once by a single movement, whilst the engines are working.

The fourth feature of these improvements is the peculiar construction of the main beams of the framing that carry the plummer blocks of the main crank shaft, to which the paddle-wheels are attached. These beams are formed as hollow trunks, by the combination of wrought iron plates attached to bars of angle iron, in the same way as ordinary boilers are made, and we are enabled by that means to construct beams of the largest dimensions of unlimited strength and of comparatively small weight.

These improvements will be more fully understood by reference to the accompanying engravings and the following description thereof, in which Fig. 1 is an elevation taken longitudinally, representing an engine with two cylinders, constructed upon the plan described as the first feature of the improvement. Fig. 2 is a vertical section of the same, taken through the cylinders. Fig. 3 is a horizontal section of a vessel, in which the situation of the engine shown at Fig. 1 is seen as it would appear when looking upon it from above; and Fig. 4 is a corresponding engine placed at the other side of the vessel, but represented in section cut horizontally through the cylinders. Fig. 5 is a vertical section taken transversely through a steam vessel, showing the positions of two engines, as in Figs. 3 and 4, the one engine being in section, the other an external view seen upon a plane in advance of the former. And Fig. 6 is a plan or horizontal view of a portion of the steam-vessel, with the engines and their appendages, and also the framing by which the crank-shafts of the paddle-wheels are supported, similar letters referring to the same parts of the machinery in all the preceding figures.

The two connected working cylinders are shewn at *a a*, their pistons at *b b*, and the piston rods at *c c*, the upper ends of which rods are affixed by keys to the cross-head *d*. Four vertical rods *e e e e*, affixed at top to the cross-head *d*, are connected at bottom to a slider *f*, which slider is enabled to move up and down on the guide-ribs *g g*, formed on the outer surfaces of the cylinders. To this slider *f* one end of a connecting rod *h* is attached, the other end of that rod being attached to the crank *i* of the propelling shaft.

From this arrangement it will be perceived that, by the simultaneous ascent and descent of the two pistons *b b* in their working cylinder *a a*, the rods *c c* will cause the cross-head *d* to move perpendicularly up and down between its guide bars *j j*, and in so doing to raise and depress the slide *f*, with the connecting rod *h*, which rod will, by that means, be made to give rotary motion to the crank *i*, and thereby cause the paddle-wheel shaft *k* to revolve. A rod *l*, connected to the slide *f*, will at the same time work the lever *m*, to which the rod of the air-pump *n* is attached.

The mode of adapting the steam-valve of the combined cylinders *a a*, is best seen in Figs. 3 and 4. The steam is admitted to, and withdrawn from, these cylinders, by one slide valve common to both, through a pipe *n*, seen in Fig. 5. From this pipe *n* the steam proceeds, through a slide valve *o* of the ordinary construction, and through the curved passages or tubes *p p* into both cylinders. There is also a narrow passage of communication always open at *q*, by which the steam is allowed to pass from one cylinder to the other for the purpose of keeping the pressure equal at all times in both cylinders.

The expansion valve is on the steam-pipe *n*, at the entrance to the slide valve. The slide is moved by an eccentric in the ordinary way; and the expansion valve is regulated by the means described hereafter under the third feature of the invention.

The advantages proposed by this arrangement are, simplicity of construction, more direct action on the crank, saving of space and weight of material, offering every means of giving larger area of cylinder, whereby a given amount of steam can be used more expansively than in former arrangements, and consequently yield more power and economize fuel, with the further advantage at sea, that when the engine is reduced in the number of its strokes by deep lading with coal, as at the commencement of a voyage, or by head winds, more steam may then be given to the cylinders, and, under such circumstances, more speed to the vessel, all the steam generated in the boiler being usefully applied.

The second feature of this invention, viz. the improved construction of steam engine having two piston rods working in one cylinder, is represented in the accompanying engravings at Figs. 7, 8, and 9. Fig. 7 is an elevation of the engine. Fig. 8, a section of the same, taken vertically through the cylinder, with the crank and shaft of the paddle-wheels; and Fig. 9 is a horizontal view, as seen from above, of the two engines and their appendages, the same letters of reference pointing out similar parts of the machinery in all the three last mentioned figures.

The cylinders of large area are shown at *a a*, and *b* are their pistons; *c c* are two perpendicular rods inserted into each piston, and working through stuffing boxes in the lid of the cylinder; *d* is a cross-head, to which the two piston-rods are keyed at top, and *e e* are the guide-rods, fixed on cast iron supports, upon which rods the cross-head *d* slides up and down. The connecting rod *f* is attached above to the cross-head, and below to the crank *g g* on the paddle shaft. The other parts of the engines will appear so obvious from inspecting the drawings, as not to require any further description.

It will be perceived that by this arrangement of the parts of the engine, motion is given to the crank-shaft below the cross-head, by a single connecting rod.

The advantages resulting from this improvement are, that a paddle-shaft, placed at a given height from the bottom of the vessel, will be enabled to receive a longer stroke of the piston than by any other arrangements now in use, a more compact and firm connection of the cylinder with the crank-shaft bearings is effected, and a cylinder of much greater diameter may be applied, by which the principle of working steam expansively may be more fully carried out, and a more direct action of the steam power on the crank obtained, with a less weight of materials and a greater economy of space than has heretofore been attained, by any of the arrangements of marine engines in use.

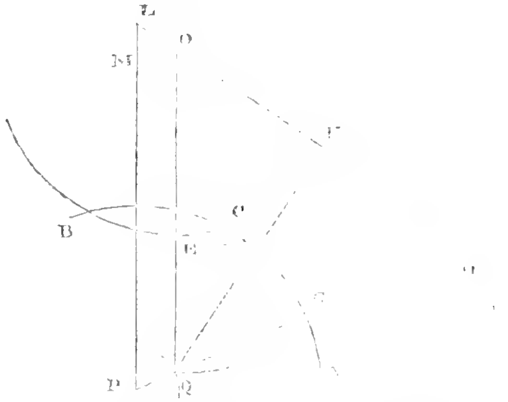
The third feature of the invention, viz. the method of adjusting the expansive valves of combined engines, regulates the flow of the steam into both engines at once, by one simple movement of the spindle and pinion, and without interrupting for a moment the working of the engines, such a means of adjustment being highly important in bringing into operation the full effect of steam applied upon the expansive principle, in economizing fuel, and adapting the power of engines to the varying circumstances at sea, between light and heavy lading, and between strong head-wind and scudding before the gale.

EXTENSIVE USE OF SLATE.—Slates are now applied to purposes unthought of till lately; and when deposited in drains, as the bottoms of tiles, are found as efficacious in keeping the land, as houses, dry. Compared to dressed freestone, or flat tile, they are at once lighter and less expensive; ease in handling is a great advantage, and equally, or more so, the alleged property of "lasting for ever." Mr. Lawrie, Terregles-town, was foremost in trying the experiment in Dumfriesshire, and his expectations have been so fully realized that his example will be very generally followed wherever drains remain to be cut, and that is sectionally, at least almost everywhere. Of the article in question he has imported from Bangor 200,000 bottoms or pieces, and may have occasion to commission further cargoes. The first imported measured six inches by five: but as these were found a kennan too small, the size has been increased an inch each way—that is seven by six. The price put on board is 7*s*. per thousand, and, as wares every way so equable pack as beautifully as herrings in a barrel, we presume, although we do not know the fact, that freightage from Wales will not greatly exceed 1*s*. additional.—*Glasgow Courier.*

RAILWAY CURVES.

On reconsidering this subject, we think, as our correspondent R. W. T. suggests, that the engineer who has to set out the line of a railway upon the ground should, in general, confine himself to the *curves*, and in every respect to the line laid down upon the plan, in which case no such question as that proposed by "An Assistant Engineer," could occur. But, since a deviation from the plan may in some instances be allowed, as "An Assistant Engineer's" question proves, we shall endeavour to solve R. W. T.'s difficulty; and for this we must first consider what may have been the cause of the failure. Now there are two cases: *either* the curve has been commenced at a wrong point of the tangent, *or* the operation of setting it out has been inaccurately performed. In the first case the error can be rectified by referring to the plan and ascertaining the right point of contact, and then setting out the curve afresh. This method would, no doubt, be exceedingly troublesome, and it appears to be the object of "An Assistant Engineer" to dispense with the labour attending such a proceeding; the question then is, what is the best method of getting over the difficulty without returning to the plan laid down, when a deviation from the latter is allowable. Now when two curves were intended to meet and form an S, and the engineer employed to set them out has not succeeded in effecting their junction, there are two cases: *either* the two curves intersect each other, *or* they do not. In the first of these cases, it is true, the two curves *may* be joined by a third, tangent to the two former, and of less radius than the one which it touches on the concave side, though, in our opinion, it would be preferable to correct the curve in accordance with the plan. Now there are an infinity of circular arcs which will satisfy the condition of being tangent to the two given curves, so that another condition must be imposed before the connecting curve can be determined; it may therefore be required, either that this curve shall touch the concave or the convex curve at a given point, or that its radius should be of a given length, which latter is the condition assumed by "An Assistant Engineer." We should recommend solving the problem on the plan and not on the ground, believing the former mode to be much more facile than the latter; we shall therefore adapt our solution to that method.

Fig. 1.



Let A B and C D, (fig. 1) be the two given curves (say of 130 chains radius), and let it be required to unite them by a third curve of less radius, tangent to A B on its concave, and to C D on its convex side.

1st case. The required curve is to pass through the point G of the curve A B.

From P, the centre of A B, and through G, the required point of contact, draw the straight line P G H, equal to the sum of the radii of the two given curves, or twice the radius P G (both curves being supposed to have the same radius); from H draw the straight line H O to the centre of the curve C D; and from K, the middle point of H O, draw the perpendicular K Q, intersecting the straight line P H at the point Q. Q will be the centre of the required curve, and its radius will be equal to Q G. Join Q O, and the point E, where Q O intersects the curve C D, will be its point of contact with the required curve.

For, the right angled triangles H K Q, Q K O being equal, Q H= Q O; and, if from these equals we take the equals G H and E O, the remainders Q G, Q E will also be equal; and, since they are situated on normals to the given curves, the circular arc G E will be tangent to both these curves.

2nd case. The required curve must pass through the point E in the curve C D.

From the centre O, and through the given point of contact E, draw the straight line O E Q; and from the centre P draw P L parallel to O Q and equal to the sum of the radii of the given curves; from P as a centre, and with a radius equal to P L, describe an arc of a circle in the direction in which the connecting curve G E is expected to meet the given curve A B, and from L draw the straight line L O H, intersecting that arc at the point H; join H P. The point Q, where H P intersects O Q, will be the centre of the required curve, and the point G, where it intersects the curve A B, will be the point of contact of the required curve with A B.

For, since O Q is parallel to L P, the triangles O H Q, L H P are similar: and consequently, L P being equal to P H, O Q = Q H: and, if from these equals we take the equals E O, G H, the remainders Q G, Q E will also be equal. And an arc of a circle passing through the points G and E, and having Q for its centre, will be tangent to the two given curves, as we proved for the first case. Or after having drawn O Q and L P, construct the isosceles triangle O L M, of which the side O M = M L; then from P as a centre, and with a radius = M L, describe an arc of a circle, intersecting O Q at the point Q, which will be the centre of the required curve, as before.

For, if through the point Q we draw the straight line P H equal to P L, we shall have, by reason of the similar triangles H Q O, H P L, Q H = Q O; and, taking away the equals G H, E O, we have Q G = Q E, as before.

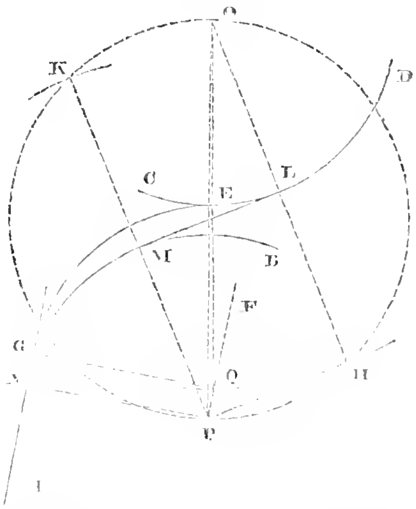
3rd case. The required curve is to have a given radius (say 100 chains).

From the point O as a centre, and with a radius equal to the sum of the radii of the given curve C D and of the required connecting curve, describe an arc of a circle in the direction in which the centre of the latter is expected to be found, and from the centre P, with a radius equal to the difference between the radius of the curve A B and that of the required curve, describe another arc, intersecting the former Q. Q will be the centre of the required curve.

For, drawing the radius P G through the point Q, the part Q G is equal to the radius of the connecting curve, since P Q is the difference between that radius and P G; also Q E is equal to the radius of the required curve, because O Q is equal to that radius, plus the radius of the curve C D, which is equal to the part O E, therefore the remaining part Q E is equal to the radius of the required curve. And it may be proved, as in the former cases, that the arc G E, described with that radius and with the centre Q, will be tangent to both the given curves.

In the case when the two curves intended to have met do not intersect each other, we should certainly recommend connecting them by a tangent, if it should not be required to make them meet, as in the plan.

Fig. 2.



Let A B, C D (fig. 2) be the given curves, the former being tangent to the straight line I A at the point A. To draw a common tangent to the two given curves.

Join (on the plan) their centres O and P by a straight line, and on O P as a diameter, describe the circumference O H P K; than from O and P as centres, and with radii equal to the sum of the radii of the two given curves, describe two arcs of circles intersecting the circumference O H P K in the points H and K respectively; draw the radii O H and P K, and the points L and M, where they intersect the given curves, will be their points of contact with the tangent, that is to say, a straight line L M, drawn through these points, will be tangent to both the given curves.

For O H and P K are parallel, and L H = P M; therefore, joining P H, L M and P H are equal and parallel; but P H is perpendicular to O H, therefore L M is perpendicular to the radius O L, and consequently tangent to the arc C D. In the same manner it may be proved to be tangent to A B. Therefore L M is the common tangent required.

If, on the other hand, it be required to move the curve A B along the tangent I A, from which it springs, until it comes in contact with the curve C D.

From the centre P draw P F parallel to I A, which produce in the direction A G; and from O as a centre, and with a radius equal to the sum of the radii of the given curves, describe an arc of a circle intersecting P F and Q. The point Q will be the centre of the curve which will touch the curve C D and the straight line T G; and, if we draw O Q and Q G, the latter perpendicular to A G, the points E and G, where these two lines cut the curve C D and the straight line A G, respectively, will be the points of contact, and the arc E G will be the required curve.

For Q G and Q E are each equal to the radius P A, and the former is perpendicular to A G, and the latter to the tangent to the curve C D at the point E. Therefore E G is the position of the required curve.

We have thus far only considered the case where the failure has resulted from making one of the curves spring from the wrong point of the tangent. In the other case, that is, when the operation of setting out one or both of the curves has been inaccurately performed, there is no remedy but to set it out again with more care.

CANDIDUS'S NOTE-BOOK. FASCICULUS XIII.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. Let B. of Derby be whoever he may, his remarks on Competition Designs are very much to the purpose; and he not only hits the right nail on the head, but gives it a clincher, when he hints very broadly that the profession have to thank themselves for the abuses which now prevail with respect to competition. If instead of merely shrugging their shoulders with a most Turk-like resignation, they were to apply them heartily to the wheel, they might extricate themselves from a position they affect to deplore. Surely if the Institute were to set about doing so in downright earnest, they might both devise and enforce a greatly better system of competition than the hollow, shuffling, delusive one now practised. Undoubtedly there are many difficulties to contend with,—first and foremost, their own apathy, indifference and want of unanimity of purpose. Some among them are notoriously opposed to competition altogether, and perhaps that the bungling and blundering now so rife in it, will sooner or later cause it to be abandoned entirely. Others seem to be afraid of making any stir about what does not immediately concern them as individuals. On that very account all the more imperative is it that the Institute as a body ought to consult the interests of the profession generally. And if competition be not a case wherein it ought to interfere with all its authority,—be not more especially one which calls for hearty co-operation, I should very much like to know where co-operation can at any time be of positive service. Were the Institute a private Club, it might be left to do as it pleased: but it is—and it may be presumed, wishes to be considered in a very different light,—to cut a figure in the eyes of the public.

II. Whether any one will agree with me or not, I incline to the opinion that so far from being at all calculated to improve architectural taste, such a work as Nash's Mansions is likely to flatter a very corrupt one, and to create a prejudice in favour of a style that taken apart from the associations and accidents, is characterized by fantastic dullness, by incoherent caprices, by expensive ugliness, and by a grotesque combination of extravagant embellishment and offensive meanness. What then, am I insensible to the charm which the mastery of the artist's pencil has communicated to the series of architectural subjects above-named? Certainly not, because it is precisely on account of the fascination with which he has invested them, that I hold them to be dangerous, and apt to seduce, and mislead those who have not the power of discriminating between the architectural deformity of many of the scenes, and the pictorial attractiveness with which they are represented. Undoubtedly many of them are highly picturesque in themselves, and rendered still more so by the manner in which they are treated, and by the adventitious interest arising from costume and figures. Still as architecture, they are for the most part naught,—absolutely frightful. Were equal witchery of effect put into it, not the homeliest merely, but nearly the most insipid subject of the kind might be rendered captivating,—an old barn, a village carpenter's shop, or the kitchen of a country inn. The chief difference would be that in such case persons would not be similarly imposed upon, but instead of attributing any beauty to the scene itself, or being at all blinded to its uncouthness, would perceive that the pleasure it affords arises entirely from the charms with which the pencil has arrayed it.

III. I should very much like to know if, among the numerous churches which have been erected of late years, there be a single one whose interior possesses, or even approximates in any degree to solemnity of character, which quality, it may be presumed, is perfectly appropriate and becoming, or, in fact, to be considered indispensable, to a place of worship. Among all the new churches I have seen, I have certainly not beheld one possessing internally any thing like solemnity in its general effect; on the contrary, differ how much they may as to all other circumstances, they agree as far as the absence of that quality goes. Some are dismal and mean enough, others, if not particularly tasteful, smart enough, just the very places for a fashionable congregation, whom the architect generally takes care to arrange so that they shall make as goodly a show as the audience of a theatre, and be able to reconnoitre each other without obstruction. In fact, there is, so far, very much more of the play-house than of the house of prayer in such buildings—nothing calculated to inspire feelings of reverence. Neither does it make much difference what style be employed, since the interiors of our modern Gothic churches have no greater air of impressive solemnity than have those in any other style. In only very few instances is there any attempt to keep up the mere corporeal semblance of the style; all its spirit, all its attractions, are gone. Richness seems to be quite out of the question, and soberness almost equally so, for notwithstanding the excessive parsimoniousness which betrays itself, there is also a good deal of vulgar jauntiness and spruceness, bad enough in itself, and thus rendered doubly odious. In some of these buildings a tawdry organ-case is the principal object, all the rest consisting only of base, coldly glaring white walls, pews and galleries, the altar itself being hardly noticeable, except on account of the meanness it displays. In short, it is to be feared that our new churches, taken generally, are not calculated to impress foreigners with any high opinion—I do not say, of our taste, but of our religious ardour, if the latter may be judged of from the externals of public worship.

IV. The Reformers have completely discomfited the Conservatives, if not in politics, most certainly in architecture. The poor Conservative Clubhouse now looks sulkier than ever, now that the rival edifice proudly displays itself in its full majesty. I gladly hail the Reform Clubhouse, as an auspicious omen of reform in architecture; it being likely to disgust with that vapid and poverty-stricken so called classical style, which at the best has given us little more than scraps and bits of Grecian architecture, and that chiefly as regards columns alone, since any thing with a shelf on top of it will, we find, do for an entablature. Good lack, my old friend Classicality, how strangely hast thou been cockneyfied since thou took up thy abode among us! It grieves one to think of it, and yet one cannot help laughing, either, at the grotesque figure thou makest in thy present costume, and what is the worst part of the business is, thou hast been thus fantastically tricked by those who all the while have professed the utmost respect for thee.

V. I was pleasingly surprized the other day by the sight of a very great rarity, namely, an architectural volume both amply and beautifully illustrated with engravings, though only a very few copies of the work was printed for distribution among the author's friends. The work appears to have been got up without the least regard to expence, and so far forms a most complete contrast to the blundering, ostentatious, niggardness manifested in the "privately printed" yet tolerably well known volume of Sir J. Soane's, containing a set of coarse and almost caricature prints, intended to show different parts of his own house. On such occasions there is no excuse whatever for stinginess, or anything like it, because a man had better keep his money in his pocket, than fling it away in purchasing for himself the reputation of being an extravagant hunks and a miserly spendthrift.

But I have not mentioned the name of the liberal-spirited individual who, in the work first alluded to, has so worthily illustrated the interior architecture of his paternal residence at Great Yarmouth—W. F. Palmer, Esq., F.S.A. Such an example ought to be made known as extensively as possible, for if there were a few more of the kind, it would not be amiss. If it be said it argues a mere mania, it is to be hoped that a mania of this kind will prove quite as catching as that which induces people to fling themselves off the Monument, to the extreme horror of those philanthropists who would read of their jumping into the Thames quite unconcernedly. Yet it is rather to be apprehended that architectural mania, amateur-mania, will never prove infectious in this country. The truth is, John Bull is likely to stick fast to his old monomania, which, in plain English, is literally a *money-mania*.

REEFING STEAM-BOAT PADDLES.

Fig. 1.

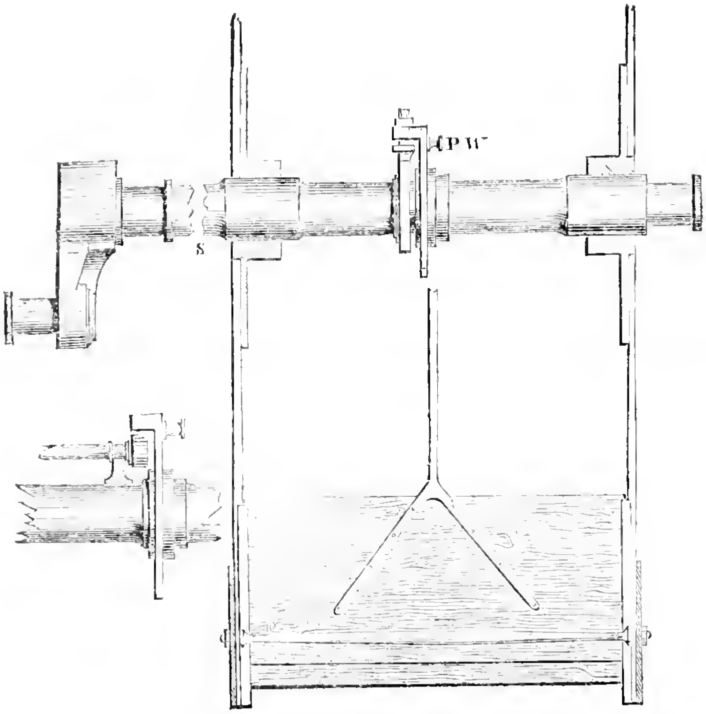


Fig.

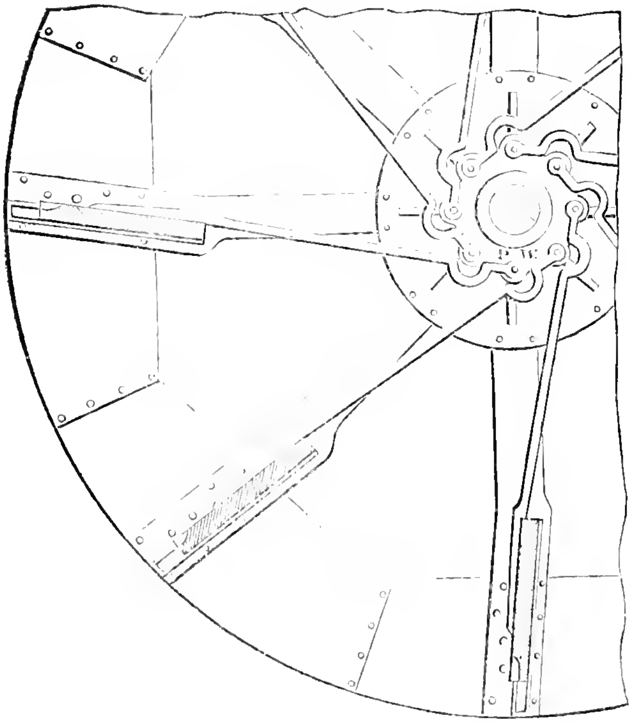


P.W, Pivot wheel. S, Shaft.

Sir,—Observing by some of the public journals that the reefing of steam-boat paddles is becoming a matter of interest, I take the liberty of sending a rough copy of a simple method executed by Messrs. Boulton, Watt & Co. for a vessel on the Tyne in the year 1815 (whose draught was variable,) it was found to answer well.

The extreme diameter when the boards were out, was 11 ft.; by the mode adopted, they could be drawn in 7½ in., reducing the diameter to 9 ft. 9 in., which was considered sufficient for a vessel of only 5 feet immersion.

By the application of a lever, the whole of the boards were moved at once, and fixed in the required position by a screw pin; this involved going into the paddle-box to make the adjustment previous to starting, but the operation is capable of being performed by a pinion working into the internal circumference of the pivot wheel (shewn in the small side figure), while the quantity of reefing may be carried to all necessary extent by enlarging its diameter.

It was the fashion in those early days of steam navigation to fit the wheels with shrouding, which, although not necessary to the scheme, I have chosen to show it as executed at that period. Should you consider this worthy of insertion, you will oblige, Sir,

Your constant reader,

London, 20th January, 1849. T. Z.

PATENT IMPROVED BOILER OR APPARATUS FOR GENERATING STEAM.

The first part of my invention consists of an apparatus (after described) for causing water in the state of dew, or divided into very minute drops or particles, to descend slowly through the interior of the boiler or generator, upon the heated surface of which, so much of it as is not converted into steam during its descent, ultimately falls; by which means a less quantity of heat is abstracted during any given time from the heated surface, than if such surface were covered with a continuous sheet or film of water, or with a body of water, as in the common boiler. And by the means I adopt, I do not merely raise steam, by wetting the heated surface, but the boiler or generator when at work is filled by dew or water in a state of minute division, which in its descent, becomes partially converted into steam, by the heat of the atmosphere or vapour within the boiler itself.

I find that a temperature of 500° or thereabouts, of Fahrenheit, in the body or substance of the boiler or generator, is that best adapted to the purpose of raising steam.

Another part of my invention consists of a self-acting apparatus, (afterwards described) for regulating the supply of water to the generator or boiler, according to the condition of the heated surfaces, and the consequent force of the steam within the boiler, that is to say, that if the boiler contains a greater body of steam, or of greater elastic force, than is necessary for the wants of the engine or other purpose to which it may be applied, then by the self-acting apparatus before referred to, the stroke of the force or supply-pump is shortened, so that when the steam is high in the boiler, the quantity of water injected becomes proportionably less; by this means, if by any chance in consequence of the boiler becoming heated to redness, or to any other degree of heat which would be highly dangerous in other boilers, or from any other cause, steam of a violently elastic force be produced, its effect is, through the medium of the above regulating apparatus, to shorten, or totally shut off, the supply of water, until the surface becoming cooler, or producing steam of less elastic force, the pump is again allowed to act; such a case, however, can never happen, excepting after the engine has been standing still for some time, and when, by neglect or design, the usual precautions and attention bestowed upon other boilers have not been observed, as the damper regulator, which is somewhat similar in effect to those in present use, will always prevent the fire being in advance, or more powerful to heat the surfaces, than the water to cool them.

In applying this invention, it will be generally found desirable to keep that part of the surface of the boiler, exposed to the immediate and corrosive action of the fire, covered with water, by which means it will be prevented from burning, and another part of my invention consists in a self-acting apparatus adapted to attain this object. By this apparatus (which is hereinafter described) the water is prevented from accumulating in the boiler beyond the quantity found best in practice, and which, in the boiler I generally use, is from three to six inches in depth over the fire; this apparatus, at the same time that it prevents the water rising in the boiler beyond a certain limit, acts upon the force-pump in a way which will be presently described, so as to reduce the quantity of water injected, if necessary.

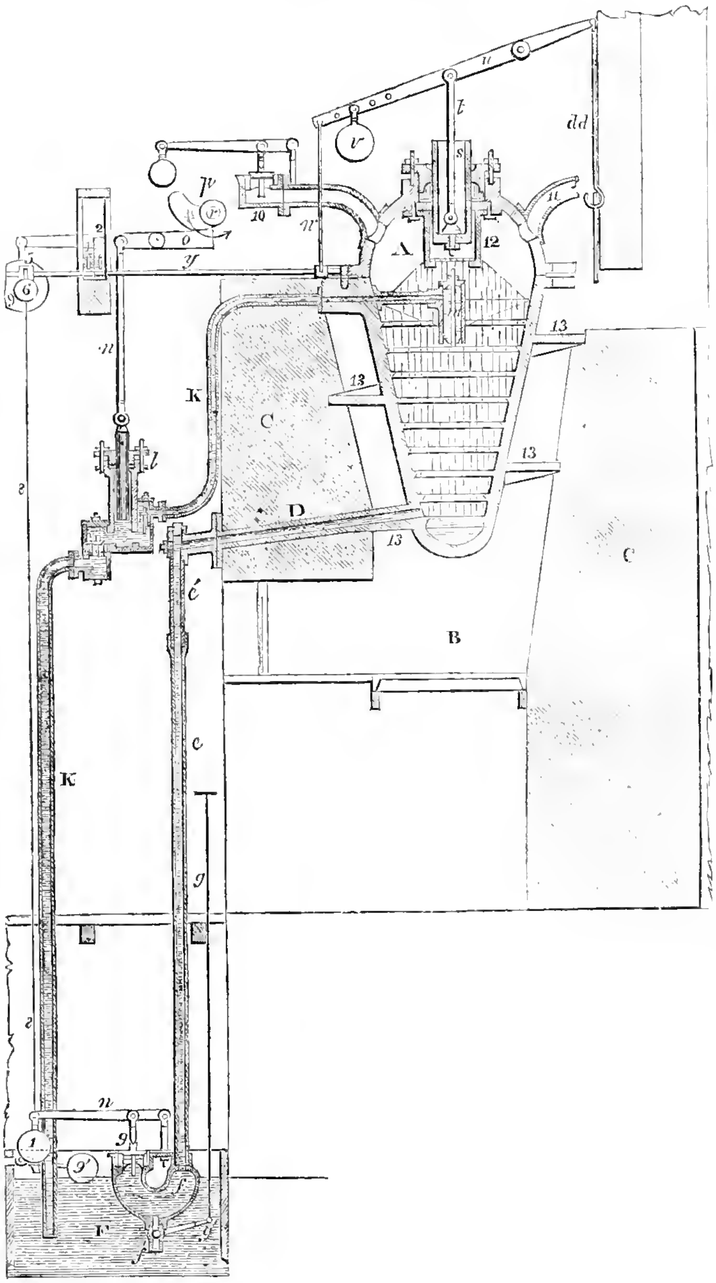
In applying my invention, I employ metal flues, by which means the fire is not only kept longer upon the surface, but the flues become carriers or depositaries of heat, and by radiation impart a certain portion of the effect of the fire upon them to the boiler, and thus economize fuel, besides adding to the strength of the boiler itself.

Another part of my invention consists in forming ridges in the interior of the boiler, by which the descent of the water over the surface is retarded, but which, although a great improvement to the action of the boiler, is not absolutely essential to it.

The external figure or shape which I have generally adopted as the best in practice, will be seen by the accompanying figure; but any convenient form may be employed, and the fire may be either external as shown in the figure, or internal according to the system usually adopted in steam-vessels.

Figure 1 exhibits a cross section of the boiler, pump, and water-

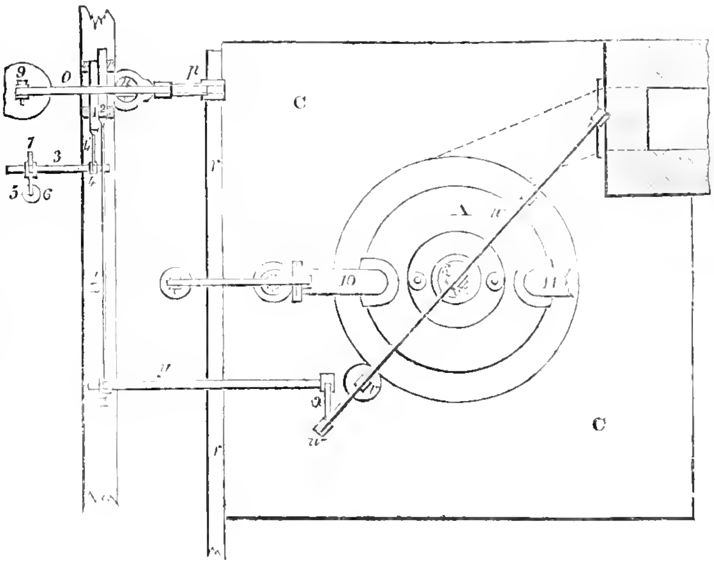
Fig. 1.—Cross section.



valve, with a representation of the water-regulating apparatus. A is a boiler, made of cast iron or other metal, around which is cast the spiral flue 13, and having its interior formed into ridges or corrugated, which ridges increase in width as they approach the bottom of the boiler. B is the fire-place, C the brickwork in which the boiler is set, D the water-pipe, by which the water in the boiler flows off as soon as it has risen to a level with the mouth of the pipe; the water then descends through the pipe *e e*, to the water-valve box *f*, and would pass out into the cistern F if not kept back by the valve *g*; the valve *g* is loaded with weight *i*, and lever *h*, so that it resists the pressure of the steam, in the same way as the safety-valve 10; but when the water accumulates in the descending pipe *e*, so that there shall be an altitude of water above the surface of the valve of from four to six feet, the valve will be unable to sustain the additional pressure of from two to three pounds per square inch upon its area, and it will lift and let out the water, until the descending column balances the weight of the valve; the cock *f* is for the purpose of blowing out any sediment which may have accumulated in the valve box, this is done by depressing the rod *g g*, attached to the lever *g'*, which is fixed on the plug of the cock.

Another mode of self-regulation for marine or other engines, when there would be an objection to the length of the pipe *e*, is as follows

Fig. 2.—Water-regulating Apparatus.



a pipe descends, and is connected with the suction-pipe of a pump, which may be either a bucket or force-pump; the exit valve or clack, is loaded by a weight and lever, like a safety-valve, with the same object as the water-valve already described, viz. that it may counteract the pressure of the steam in the boiler. When the pump is full of water, the action of the plunger will force out of the pump as much water as it displaces in its descent, and draw into the pump from the pipe a corresponding quantity of water, thus emptying the pipe, and preventing the water rising above its proper level in the boiler.

A glass tube is employed at *e'*, by which the state of the water may always be observed, and the usual brass mounting is attached, for the purpose of cleaning either the lying or vertical pipes; C is the force or supply-pump, the suction-pipe K' draws its supply from the cistern F, so that the hot water escaping from the boiler is used over again and no heat lost; *k* is the injection pipe of the pump connected with the nozzle *m*; at about one-third its length from the bottom, the nozzle is perforated with a circle of small holes, drilled so as to discharge the water in a direction slanting upwards, or in such a direction that it may be reflected upwards from the sides of the boiler or generator, (any number of holes in any figure which experience may suggest may be adopted), the best plan I find is to make them about a quarter of an inch apart, and about the hundredth part of an inch in diameter, and drilled in such way that they may be largest outside, by which means they will be less likely to be clogged up; the ends of the nozzle are loose, the upper end screws into its place, and the lower end is made a good joint and ground in, so that when the bolt which passes through it, and the upper end is screwed with a nut and spanner from the top, the nozzle becomes perfectly closed, and no water can escape excepting through the small perforations in the sides; it is necessary to form the ends loose, or provide some other adequate means to discharge the sediment, which may from time to time collect in the nozzle; this adjustment is easily made by merely taking out the plunger *s*, and the perforated plate *s'*, when a spanner can be introduced into the boiler, and the nut or upper end unscrewed as may be required; sometimes the nozzle is formed in a circle with jets like a gas burner, but the above described method I have found to be the best.

The action of the injected water is clearly seen by the dotted and prolonged descendieg lines, the water impinges violently against the sides of the vessel, and is then thrown off at an equal angle in an opposite direction, after which it descends in a vertical shower as shown, it is not necessary that this mode should be always observed, any mode is good that minutely divides the water, and then allows it to descend slowly upon the heated surfaces may be adopted to my invention; but it is essential that the water should be first discharged upwards, either in an inclined direction or perpendicularly, or that it should be discharged in such a direction that it may be reflected upwards, or slanting upwards from the sides of the boiler.

The plunger of the pipe C is connected by the link *n* with the lever *o*, this lever is worked by the cam *p*, fixed on the shaft *r*, which shaft is driven by any of the usual and suitable modes from the engine, or any other equivalent mode of lifting the lever may be adopted; to the end opposite to that on which the cam acts, is suspended the weight *q*, so that the cam lifts the plunger and the weight gives the stroke, producing a sudden and violent rush of the water through the holes of the nozzle *m* which very materially affects that minute division of the water which is necessary to the perfect action of the boiler, *s* is a plunger or piston working through a stuffing box, upon the top of the boiler connected by the link *t*, with the lever *u*, which lever works upon the centre *v*, to the end next the chimney is attached the rod of the damper *dd*, and to the other end the weight *v*, and the rod *w*, thus when the steam rises, it acts upon the plunger or piston *s*, this raises the end of the lever *u*, upon which the weight *v* is suspended, and the rod *w* attached, and depresses the other end to which the damper is attached, thus damping the fire as in the usual way, the lever *u* in the act of rising by the increasing elasticity or volume of the steam lifts the rod *w*, and likewise the end of the crank or lever *x*, to which the other end of the rod *w* is attached, this crank or lever is fixed upon one end of the cross shaft *y*, and to the other end of the shaft, and at right angles with the crank *x* is fixed another and shorter crank *z*, thus when the crank *x* is raised vertically by the action of the steam plunger *s*, it causes the shorter crank *z* to move horizontally forwards, this horizontal movement is continued through the medium of the rod or bar *z'*, connected with the short crank *z* at one end, and the other end with the wedge 2, thus pushing the wider part of the wedge under the pump lever, and by this means shortening the stroke or descent of the pump plunger, this movement may be also effected by a rack and pinion, or by a screw and pinion, or by other means.

I do not claim the plunger or piston as new, to regulate the damper, an analogous contrivance, having already been made; that part of my invention which I have before referred to as a self acting apparatus for preventing an undue accumulation of water in the bottom of the boiler, is as follows: to the extreme end of the lever *h*, of the water-valve, is fixed a slight bar, wire, or chain, 8; the other end of the wire or chain is connected to the short horizontal crank 7, fixed upon the short cross shaft 3; to the longer arm 5 of the horizontal crank, is suspended the weight 6, which weight, when the wire or chain is slackened, descends, and descending, produces motion in the shaft 3, to which the crank is fixed, and also in the short crank 4, fixed upon the other end of the cross shaft 3; thus as the weight descends, the crank 4, by means of the rod 4', connected with it, and the wedge 1, draws the wedge 1 forward; by the wider part being thus drawn or introduced under the lever *o* of the pump, the stroke of the pump is shortened, and the supply of water consequently diminished. I do not confine myself to the particular modification of machinery here described for effecting this object, but any other adapted to the purpose may be used; thus for instance, another mode of regulating the action of the pump, is by forming the descending tube about 8 or 10 inches internal diameter, and placing therein a float, which shall rise and fall with the water in the tube in the same way as the float in the feed head of a common boiler regulates the damper, then a wire passing through a stuffing box in the upper part of the pipe *c*, and communicating with the crank 7, in the same way as the wire 8, the same movement will take place in the wedge 1, as has been before described; in the case of a locomotive where the pump plunger is connected with the cross head of the piston rod, and works very fast; the method to be adopted to reduce the stroke of the pump, will be to make the barrel of the pump moveable, then by means of a screw fixed to the end, and causing the nut in which the screw works to be acted upon either by the steam plunger or the lever of the water valve, and thus making the barrel of the pump advance towards, or recede from the plunger, the same regulating process will be easily applicable; it will be merely necessary that the suction and injection pipe should work in stuffing boxes, or by making them elastic to allow for the variation; 9 is the pipe and cock for supplying the water cistern with water, 9' is the ball-cock which keeps the water to its level, 10 is the safety valve, 11 the steam pipe, 12 the steam casing in which the plunger works, the lower part is covered with a plate perforated with holes, so that the steam plunger may work more steadily, and not be acted upon so suddenly by the steam, as the steam before acting upon the plunger will pass through the holes of the plate, and thus a certain regularity of action will be preserved, which could not be ensured without it.

A boiler upon this construction, but made in a very rude manner for the purpose of experiment, 2 ft. deep, 1 ft. over at the bottom, and 2 ft. wide at the widest point, was at work for some time driving a 6 horse condensing engine at Messrs. Burton & Sons, engineers, Bankside, but now of Holland Street, Blackfriars Road; the area exposed to the fire was about 8 ft., and this drove the engine fully loaded, the steam blowing off during the greater part of the time; it had no tendency to get red hot, and upon several occasions, for the mere purpose of the experiment, the engine was stopped, and the boiler purposely made red hot, when the only result that followed was a rapid generation of steam whilst the water was pumped into the boiler; by this apparatus the great desideratum of a powerful, portable, and safe boiler is obtained, and I feel certain that in a properly constructed vessel, a velocity of 20 miles per hour through the water can be easily accomplished.

Stamford Street, W. J. CURTIS.
Blackfriars Road.

ON THE PRESSURE OF WATER AND THE STRENGTH OF COFFER-DAMS.

By John Neville, C. E.

The following propositions are intended to furnish rules for calculating the dimensions of coffer dams from having the depth of water, and the specific gravity of the materials to be used in the dam given. The construction of the coffer dam is supposed to be that generally adopted, namely, two or more rows of piles having the spaces between filled with clay, or a mixture of clay and gravel, the whole united into one mass by walings, bolts, &c. And it will be seen that the dimensions found from the investigated formulæ do not differ materially from those adopted with success by many celebrated engineers.

The pressure arising from mere depth of water is not the only force to be prepared against in constructing a coffer dam, as moving water or an exposed situation must also be taken into consideration. These latter I have not calculated for in the following problems, as I consider they are sufficiently provided for by the resistance of the piles penetrating the bottom, which assists the solidity of the dam; and by the auxiliary aid of stays and braces, and have determined the dimensions of the dam itself as only sufficient to resist the pressure of an outside depth of dead water.

Problem I.

To determine the amount of pressure against a coffer dam or obstruction, the depth of water being given.

Put c for the depth of water in feet. The pressure on each point of the dam is as the depth of that point from the surface of the water; the whole pressure for the depth c is therefore represented by the area of a right angled triangle having the base and perpendicular each equal to c, or by $\frac{c^2}{2}$. The weight of a cubic foot of water may be taken at $62\frac{1}{2}$ lbs.; hence we have $62\frac{1}{2}\times\frac{c^2}{2}=\frac{125c^2}{2}$ for the pressure on each foot in length of the dam in lbs., which, multiplied by the length, will give the whole pressure required.

Example 1.—What is the pressure on each foot in length of a coffer-dam, the water inside being exhausted, and the depth of water outside being equal to 15 feet?

Here $c=15$ and $\frac{125c^2}{2}=\frac{125\times15\times15}{2}=14062\frac{1}{2}$ lbs., the pressure required.

Example 2.—What is the pressure against a coffer dam whose girth is 60 feet, the depth of water outside being 20 feet?

Here we have $\frac{125\times20\times20}{2}=25000$ lbs. for the pressure on each foot in length, therefore $25,000\times60=1,500,000$ lbs. is the pressure required.

Problem II.

To find the effective pressure against a coffer dam or lock gate, the depth of water outside being given: a given depth of water being inside.

Put c for the outside depth of water, and d for that inside, we then get $\frac{125c^2}{2}-\frac{125d^2}{2}=\frac{125\,(c^2-d^2)}{2}=\frac{125\times(c+d)\times(c-d)}{2}$ for the pressure on each foot in length, when the inside and outside girths are equal; putting therefore g for either girth, we get $\frac{125\times(c+d)\times(c-d)\times g}{2}$ for the pressure required.

Example 1.—Given the depth of water on the outside of a dam equal 20 feet, that inside equal 6 feet, and the girth 60 feet, what is the effective pressure against the dam?

We have $c+d=26$, $c-d=14$, and $g=60$ therefore

$$\frac{125\times(c+d)\times(c-d)\times g}{2}=\frac{125\times26\times14\times60}{2}=125\times26\times14\times30$$

$=45,500\times30=1,365,000$ lbs. for the effective pressure.

When the inside and outside girths differ, by putting g for the outside girth, and g' for that inside, we get in this case $\frac{125(c^2g-d^2g')}{2}$ for the effective pressure.

Example 2.—Given the height of water on the sill to the upper gates of a lock above, 10 feet and girth 24 feet; below 4 feet and girth 25 feet—what is the effective pressure on the gates?

The pressure is equal $\frac{125(c^2g-d^2g')}{2}=\frac{125(100\times24-16\times25)}{2}$

$=125(100\times24-8\times25)=125\times1000=125,000$ lbs. the pressure required.

Example 3.—Find the effective pressure against a coffer dam, the exterior depth and girth respectively being 27 and 120 feet; and the interior depth 5 feet, and girth 100 feet.

Here by the formulæ $\frac{125(27\times27\times120-5\times5\times100)}{2}=$

$125(729\times60-25\times50)=125\times42490=5,311,250$ lbs. the pressure required.

Problem III.

To find the centre of pressure in a given depth of water: or that point where the force of the whole pressure is equal to the sum of the forces arising from the pressures at different depths from the surface.

The whole pressure (problem 1) is represented by a right angled triangle having its base and perpendicular each equal to the depth of water, and as the pressure at each point along the depth is proportional to the depth of such point from the surface, or which is the same thing to a line parallel to the base at that point meeting the hypothenuse; the centre of pressure is evidently on the same horizontal line with the centre of gravity of the triangle. But the latter is at one third of the perpendicular from the base, therefore the centre of pressure is at one-third of the depth of water from the bottom, or $\frac{1}{3}c$.

Examples. The centre of pressure in 15 feet of water is 5 feet above the bottom: in 18 feet of water at 6 feet above the bottom: and in 30 feet of water at 10 feet above the bottom.

Problem IV.

To find the centre of pressure when given depths of water are inside and outside a coffer-dam.

By putting as before c for the depth outside, and d for that inside, we find the outside pressure acting at the distance $\frac{1}{3}c$ from the bottom equal $\frac{125c^2}{2}$ (problems 1 and 3), and the inside pressure acting at the distance $\frac{d}{3}$ equal $\frac{125d^2}{2}$. The centre of pressure is now therefore in the fulcrum of a lever, whose length is $\frac{c-d}{3}$, which lever is acted on at its ends by the two pressures $\frac{125c^2}{2}$ and $\frac{125d^2}{2}$. To find this point we have $\frac{125c^2}{2}+\frac{125d^2}{2}:\frac{c-d}{3}::\frac{125d^2}{2}:\frac{(c-d)\times d^2}{3(c^2+d^2)}$ the distance of the fulcrum from a point corresponding to $\frac{1}{3}c$, therefore $\frac{c}{3}-$

$$\frac{(c-d)\times d^2}{3(c^2+d^2)}=\frac{c^3+cd^2-cd^2-d^3}{3(c^2+d^2)}=\frac{c^3+d^3}{3(c^2+d^2)}.$$

The distance of the point required from the bottom of the water from which we deduce the following rule:—

Divide the sum of the cubes of the inside and outside depths by three times the sum of their squares, the quotient will be the distance of the centre of pressure from the bottom of the water.

Example.—Take $c=20$ and $d=10$ we then have

$$\frac{20^3+10^3}{3(20^2+10^2)}=\frac{8000+1000}{3\times500}=\frac{9000}{1500}=6$$ feet for the distance of the centre of pressure from the bottom.

Problem V.

To find the centre of pressure in a depth of water lying between the depths c and d below the surface.

Let c be the greater depth, and put x for the distance of the centre of pressure in the depth $c-d$, from the centre of pressure in the depth c; we then have from the properties of the lever

$$x\times\frac{125(c^2-d^2)}{2}=\frac{2(c-d)}{3}\times\frac{125d^2}{2},$$

from which equation by an easy reduction we find $x=\frac{2d^2}{3(c+d)}$ therefore $\frac{c}{3}-\frac{2d^2}{3(c+d)}$ is the distance of the point required from the bottom of the depth c, and $\frac{2c}{3}+\frac{2d^2}{3(c+d)}$ its distance from the surface of the water.

Example 1.—In 15 feet depth of water what is the distance of the centre of pressure of the lowest 5 feet from the bottom?

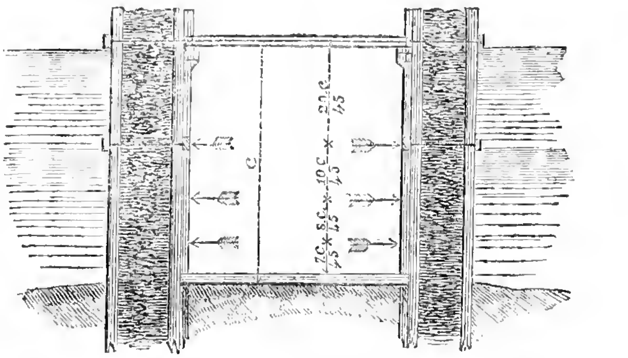
Here $\frac{c}{3}=5$ and $\frac{2d^2}{3(c+d)}=\frac{2\times10^2}{3\times(15+10)}=\frac{200}{75}=\frac{8}{3}$ feet, therefore $\frac{c}{3}-\frac{2d^2}{3(c+d)}=5-\frac{8}{3}=\frac{7}{3}$ feet the distance required.

Example 2.—Two stays support a coffer-dam at depths of 20 and 10 feet below the surface of the water, and it being found necessary to place another between these, at what distance shall we place it from the lower stay, so that it may afford the greatest assistance possible?

It is easy to see that the third stay must be applied opposite the centre of pressure. To find this point we have $c=20$ and $d=10$, therefore $\frac{c}{3}-\frac{2d^2}{3(c+d)}=\frac{20}{3}-\frac{2\times10^2}{3(20+10)}=\frac{20}{3}-\frac{200}{90}=\frac{20}{3}-\frac{20}{9}=\frac{60-20}{9}$ $=\frac{40}{9}=4\frac{4}{9}$ feet, the distance required.

A proper knowledge of the position of the centre of pressure will enable us to place our stays with advantage and economy, particularly in those cases where a coffer-dam is surrounded with water. If the top and bottom of such a coffer-dam (fig. 1) are kept from approaching

Fig. 1.

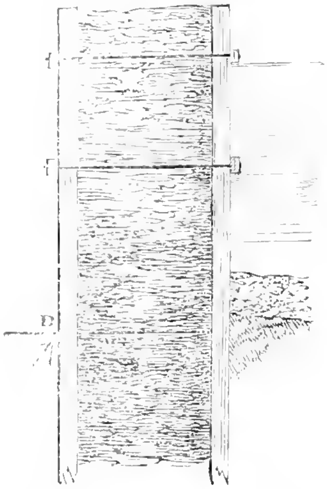


each other, the next best point to secure is evidently at the centre of pressure of the whole depth of water, or using the same notation as before at $\frac{1}{3}c$ from the bottom. If more stays are necessary, the most important points to be secured are those at the distance $\frac{7c}{45}$ and $\frac{5c}{9}$ from the bottom, or in other words at the points corresponding to the centres of pressure in the lower and upper portions of the depth $\frac{c}{3}$ and $\frac{2c}{3}$.

Problem VI.

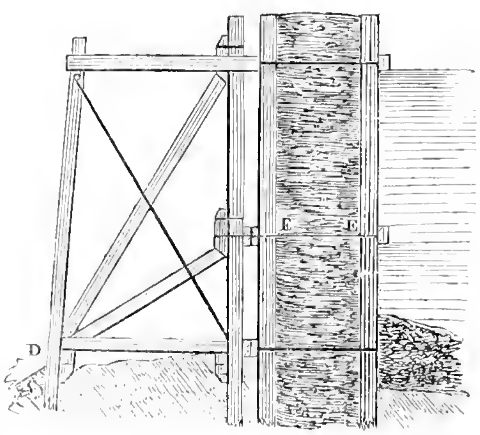
To find the dimensions of a coffer-dam fig. 2 sufficient to resist the pressure of a given depth of water when the section is rectangular.

Fig. 2.



Put s for the mean weight in lbs. of a cubic foot of the materials in the dam, b for its height in feet, d for its width in feet, and c for the depth of high water in feet. We then have $b\,d\,s$ equal the weight of one foot in lenght. It is evident that the dam fails only when the force of the water is able to turn it round the point D, and as the weight $b\,d\,s$ acts at the distance $\frac{d}{2}$ from D in the figure its force is properly represented by $b\,d\,s \times \frac{d}{2} = \frac{b\,d^2 s}{2}$. The pressure of the water is equal $\frac{125c^2}{2}$ (problem 1,) which acting at the distance $\frac{c}{3}$ above D (problem 3) has its force represented by $\frac{125c^2}{2} \times \frac{c}{3} = \frac{125c^3}{6}$. Therefore in case of equilibrium we have $\frac{b\,d^2 s}{2} = \frac{125c^3}{6}$ from which equation we find $d^2 = \frac{125c^3}{3\,b\,s}$ and $d = \sqrt{\frac{125c^3}{3\,b\,s}}$. From this proposition it is clear that when $b=c$, *the width d of the dam is proportional to the depth of the water, and that the power of water to overturn a dam is as the cube of its depth.* The value of s will depend on the nature of the puddle used in the dam, and the proportion it bears to the quantity of timber and iron in the width d. In the examples to this and the following problems, s is supposed to be equal to 90 lbs., which in most cases may not be far from the true value, except in those cases where the water penetrates under the dam when it must be reduced to about one-third, or to 30 lbs. nearly.

Fig. 3.



Example 1.—Find the width of a coffer-dam sufficient to resist the pressure of 17 feet of water on the outside, the height of the dam being 19 feet.

Here we have

$$d = \sqrt{\frac{125c^3}{3\,b\,s}} = \sqrt{\frac{125 \times 17^3}{3 \times 19 \times 90}} = \sqrt{\frac{614125}{5130}} = \sqrt{116{\cdot}4} = 10{\cdot}8 \text{ feet.}$$

If $b=c=17$ feet, then $d=17\sqrt{\frac{125}{270}}=11{\cdot}6$ feet. If we suppose from want of proper precaution the water to penetrate under the dam, s is reduced to about $\frac{s}{3}$ for the height c, say $\frac{s}{n}$, we then get

$\overline{(b-c)\,ds+cd} \times \frac{s}{n} \times \frac{d}{2} = \frac{125c^3}{6}$ for the equation of equilibrium from which we find $d^2 \times (3\,nbs + 3cs - 3\,ncs) = 125c^3 n$ and

$d = \sqrt{\frac{125nc^2}{3nbs+3cs-3ncs}}$. When $n=3$ as would be nearly the case in practice, $d = \sqrt{\frac{125c^3}{s \times (3b-2c)}}$. By using the numbers in example 1, we get by this formulæ

$d = \sqrt{\frac{125 \times 17^3}{90 \times (57-34)}} = \sqrt{\frac{614125}{2070}} = \sqrt{296{\cdot}7} = 17{\cdot}2$ feet, shewing under these circumstances a necessary increase of nearly six feet in width.

Example 2.—What width of dam is sufficient to resist the pressure of 17 feet depth of water, the dam to rise 4 feet above the surface, when the bottom is porous gravel communicating with the water.

In this case we have

$$d = \sqrt{\frac{125c^3}{90(3\,b-2\,c)}} = \sqrt{\frac{125 \times 17^3}{90 \times (63-34)}} = \sqrt{\frac{614125}{90 \times 29}} = \sqrt{\frac{614125}{2610}} = \sqrt{235{\cdot}3} = 15{\cdot}3 \text{ feet.}$$

PROBLEM VII.

To find the strength of a coffer-dam (fig. 3) sufficient to resist the pressure of a given depth of water so that by the intervention of stays, &c. the coffer-dam could only fail by the failure of the point D.

Put k for the distance E D, d for the distance E F, and by using the same notation as before for the other dimensions, we get by the properties of the lever $bds \times (\frac{d}{2}+k) = \frac{125c^2}{2} \times \frac{c}{3}$ for the equation of equilibrium, and by reduction $d^2 + 2\,kd = \frac{125c^3}{3\,bs}$ from which we find

$$d = \sqrt{\frac{125c^3}{3\,bs} + k^2} - k.$$

Example 1.—Find the width d when $k=18$, $c=17$, and $b=21$ feet, here $\sqrt{\frac{125c^3}{3\,bs}+k^2}-k = \sqrt{\frac{125 \times 17^3}{3 \times 21 \times 90}+18^2}-18 = \sqrt{\frac{614125}{5670}+32{\cdot}4}-18 = \sqrt{649}-18 = 25{\cdot}5-18 = 7{\cdot}5$ feet$=d$. These were nearly the dimensions of the coffer-dam for building the river wall at the New Houses of Parliament (see Journal, vol. 1, page 31). But this coffer-dam was still held more firmly on its base by the resistance to the piles penetrating the silth and clay substratum requiring a considerable force to overcome it, over and above that which was already sufficiently resisted by the upper portion of the coffer-dam.

When d is given we find from the equation $d^2 + 2\,dk = \frac{125c^3}{3\,bs}$.

$$k = \frac{125c^3}{6\,bsd} - \frac{d}{2}.$$

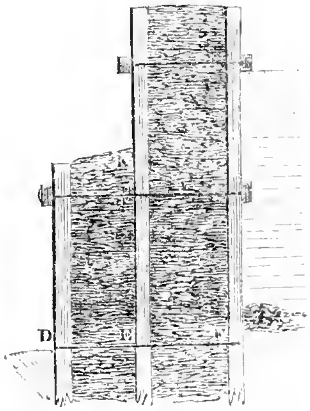
Example 2.—At what distance from the inner sheet pileing of a coffer-dam 10 feet wide shall we place the brace pileing D, so that when properly braced the dam shall resist the pressure of 30 feet depth of water outside. The dam rising 4 feet above the surface.

Here $k = \frac{125 \times 30^3}{6 \times 34 \times 90 \times 10} - \frac{10}{2} = \frac{3375000}{18360} - 5 = 18{\cdot}4 - 5 = 13{\cdot}4$ feet the distance required. If $s=30$ as would be nearly the case if the bottom was porous, k should be increased to about $3\times18\cdot1-5=55.2-5=50$ feet. This shows the importance of securing the bed of the dam from water by dredging, or otherwise clearing away all porous materials.

Problem VIII.

To find the strength of a dam (form fig. 4) sufficient to resist the pressure of a given depth of water.

Fig. 4.



By using the same notation as before, putting f for E K, and k for D E, we get $s\,b\,d\times(\frac{d}{2}+k)+s\,k\,f\times\frac{k}{2}=\frac{125c^2}{2}\times\frac{c}{3}$ for the equation of equilibrium from which $s\,b\,d^2+2\,s\,b\,d\,k+s\,f\,k^2=\frac{125c^3}{3}$. This equation gives us $d^2+2\,d\,k=\frac{125c^3}{3\,bs}-\frac{k^2f}{b}$ and $k^2+\frac{2\,b\,d}{f}k=\frac{125c^3}{3\,sf}-\frac{b\,d^2}{f}$. From these we find $d=\sqrt{\frac{125c^3}{3bs}+\frac{(b-f)k^2}{b}}-k$ (1), and

$k=\sqrt{\frac{125c^3}{3sf}-\frac{b\,d^2}{f}+\frac{b^2\,d^2}{f^2}}-\frac{b\,d}{b}$. (2). From these values for d and k we can find one when the other is given.

Example 1.—Having given $k=4$ feet, $f=10$ feet, $b=21$ feet, and $c=17$ feet, to find the value of d?

By equation (1) $d=\sqrt{\frac{125c^3}{3bs}+\frac{(b-f)k^2}{b}}-k=\sqrt{\frac{614125}{5670}+\frac{176}{21}}-4=\sqrt{108\cdot3+8\cdot4}-4=\sqrt{116\cdot7}-4=10\cdot8-4=6\cdot8$, or 7 feet nearly, the value required.

Example 2.—Suppose $k=10$ feet, $f=17$ feet, $b=33$ feet, and $c=30$ feet, what is the width (d) equal to?

Here $d=\sqrt{\frac{125\times30^3}{3\times33\times90}+\frac{16\times10}{33}}-10=\sqrt{\frac{12500}{33}+\frac{1600}{33}}-10=\sqrt{\frac{14100}{33}}-10=\sqrt{427\cdot3}-10=20\cdot7-10=10\cdot7$ feet, the width required.

Example 3.—To find the value of k when $d=6$ feet, the other dimensions remaining the same as in Example 1.

From equation (2) $k=\sqrt{\frac{125c^3}{3sf}-\frac{b\,d^2}{f}+\frac{b^2d^2}{f^2}}-\frac{b\,d}{f}=$

$\sqrt{\frac{614125}{2700}-\frac{756}{10}+\frac{15876}{100}}-\frac{126}{10}=\sqrt{227\cdot5-75\cdot6+158\cdot8}-12\cdot6=$

$\sqrt{310\cdot7}-12\cdot6=17\cdot6-12\cdot6=5$ feet, the value sought.

Example 4.—To find the value of k when $d=10$ feet, the other dimensions remaining the same as in Example 2.

Here $k=\sqrt{\frac{125\times30^3}{3\times90\times17}-\frac{33\times10^2}{17}+\frac{33^2 10^2}{172}}-\frac{33\times10}{17}=$

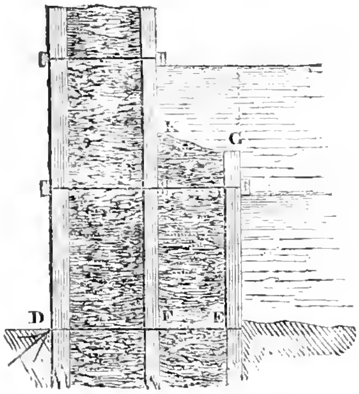
$\sqrt{\frac{12500-3300}{17}+\frac{108900}{289}}-\frac{330}{17}=\sqrt{541\cdot2+376\cdot8}-19\cdot4=$

$\sqrt{918}-19\cdot4=30\cdot3-19\cdot4=10\cdot9$ feet, the value sought.

Problem IX.

To find the strength of a coffer-dam fig. 5, sufficient to resist the pressure of a given depth of water.

Fig. 5.



Here, by putting k' for F E, and f' for K F, we have

$$\left(\frac{k'}{2}+d\right)\times s\,k'f'+\frac{d}{2}\times s\,d\,b=\frac{125\,c^2}{2}\times\frac{c}{3},$$

for the equation of equilibrium by disregarding the vertical pressure of the water above K G, and thence $s\,k'^2f'+2\,s\,d\,k'f'+d^2s\,b=\frac{125c^3}{3}$; from this equation we get

$$d^2+\frac{2\,k'f}{b}d=\frac{125\,c^3}{3\,b\,s}-\frac{k'^2f'}{b}$$

and $k'^2+2\,d\,k'=\frac{125\,c^3}{3\,sf'}-\frac{d^2\,b}{f'}$; these equations give

$$d=\sqrt{\frac{125\,c^3}{3\,s\,b}-\frac{k'^2f'}{b}+\frac{k'^2f'^2}{b^2}}-\frac{k'f'}{b} \qquad (1).$$

$$\text{and } k'=\sqrt{\frac{125\,c^3}{3\,sf'}-\frac{b\,d^2}{f'}+d^2}-d \qquad (2).$$

Example 1.—When k' is equal 4 feet, what is the value of d, the other dimensions being the same as those in example 1, problem 8.

From equation (1) $d=\sqrt{\frac{125\times17^3}{3\times90\times21}-\frac{4^2\times10}{21}+\frac{10^2\times4^2}{21^2}}$

$$-\frac{10\times4}{21}=\sqrt{\frac{614,125}{5670}-\frac{160}{21}+\frac{1600}{441}}-\frac{40}{21}$$
$$=\sqrt{108\cdot3-7\cdot6+3\cdot6}-1\cdot9=\sqrt{104\cdot3}-1\cdot9$$
$$=10\cdot2-1\cdot9=8\cdot3 \text{ feet.}$$

Example 2.—Using the same dimensions as in example 2, problem 8, what is the value of d?

$$d=\sqrt{\frac{125\times30^3}{3\times33\times90}-\frac{10^2\times17}{33}+\frac{10^2\times17^2}{33^2}}-\frac{10\times17}{33}$$
$$=\sqrt{\frac{12,500-1700}{33}+\frac{28,900}{1089}}-5\cdot2=$$

$\sqrt{327\cdot3+26\cdot5}-5\cdot2=\sqrt{353\cdot8}-5\cdot2=18\cdot9-5\cdot2=13\cdot7$ feet.

Example 3.—Using the same dimensions as those in example 3, problem 8, what is the value of k?

From equation (2) $k=\sqrt{\frac{125\times17^3}{3\times90\times10}-\frac{21\times6^2}{10}+6^2}-6$

$=\sqrt{227\cdot5-75\cdot6+36}-6=\sqrt{187\cdot9}-6=13\cdot7-6=7\cdot7$ feet.

Example 4.—Using the same dimensions as those for example 4, problem 8, what is the value of k'?

$$k'=\sqrt{\frac{125\times30^3}{3\times90\times17}-\frac{10^2\times33}{17}+10^2}-10$$

$$= \sqrt{\frac{12{,}500 - 3300}{17} + 100} - 10 = \sqrt{\frac{9200}{17} + 100} - 10$$

$$= \sqrt{541{\cdot}2 + 100} - 10 = 25{\cdot}3 - 10 = 15{\cdot}3 \text{ feet.}$$

If we take into consideration the weight of the water above K G, the values found for d and k in the examples are too high; but the gravity of the materials in the dam being to the gravity of the water as s to $62\frac{1}{2}$, if we substitute $f' + \overline{c - f} \times \frac{2s}{125}$, or $f' + \overline{c - f'} \times \frac{2}{3}$ (nearly), for f' in the general equations (1) and (2), we will find correct values for d and k. Thus in examples 1 and 3, $f' = 10 + \overline{17 - 10} \times \frac{2}{3} = \frac{44}{3}$, and in examples 2 and 4, $f' = 17 + \overline{30 - 17} \times \frac{2}{3} = \frac{77}{3}$; using these values of f' we would find in

Example 1.—$d = 7{\cdot}4$ feet;
Example 2.—$d = 11{\cdot}2$ feet;
Example 3.—$k = 5{\cdot}9$ feet;
Example 4.—$k = 11{\cdot}4$ feet;

all of which are intermediate between the former values and those found in the examples of problem 8. It appears therefore in these examples that fig. 4 is to be prefered to fig. 5. If we wish to have equal strength in these two forms, we get by equating the general equations in problems 8 and 9, $s\,b\,d^2 + 2\,s\,b\,d\,k + s\,k^2 f = s\,k'^2 f' + 2\,s\,d\,k' f' + d^2 s\,b$, and thence $2\,b\,d\,k + k^2 f = k'^2 f' + 2\,d\,k' f'$, which equation will furnish the value of any of the quantities when the others are given. By substituting $f' + \frac{2c - 2f'}{3} = \frac{2c + f'}{3}$ for f', we take into consideration the weight of water over K G; in assisting the stability of the dam Fig. 5, this substitution gives us $6\,b\,d\,k + 3\,k^2 f = 2\,c\,k'^2 + 4\,c\,d\,k' + (k'^2 + 2\,d\,k')f'$, for a general equation of equal strength in both forms.

The subject we have now been considering, is closely connected with the consideration of the comparative strength of buttresses and contreforts to retaining walls. If we put n for the weight of a cubic foot of earthwork or filling, and s for that of masonry, and substitute $f' \times \frac{\overline{c - f'} \times n}{s}$ for f' in the equation $2\,bdk + k^2 f = 2\,dk'f' + k'^2 f'$, we get $2\,bdsk' + k^2 f s = (k'^2 + 2\,dk') \times \frac{nc + (s - n)f'}{s}$ for a general equation of equal stability between buttress and contrefort, by which we may with ease determine any of the dimensions by having the others given, as none of the quantities rise higher than the second power. The quantity $\frac{\overline{c - f'} \times n}{s}$ is the height of a prism of masonry equal in weight to a prism of clay whose height is $c - f$. This prism acts with the clay or filling in moving out the wall, and also, from its weight on the contrefort, gives the latter greater stability. This double action often separates the contrefort from the main wall when both are not well bonded into each other.

Having pointed out the method of taking the weight over K G, Fig. 5 into account, where considered necessary, we will neglect it in the examples to the following problem, though the formulæ are general by substituting $\frac{2c + f'}{3}$ for f'.

PROBLEM X.

To find the dimensions of a coffer-dam, Fig. 6, sufficient to resist the pressure of a given depth of water.

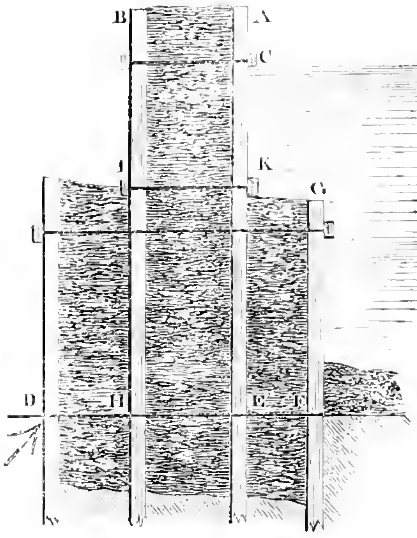
By observing the same notation as in the former problems, we get from the principles of the lever,

$$s f' k' + (k + d + \frac{k'}{2}) + s\,b\,d \times (k + \frac{d}{2}) + s f k \times \frac{k}{2} = \frac{125 c^2}{2} \times \frac{c}{3}$$

for the equation of equilibrium, and by reduction we find $2\,k\,k' f' + 2\,k' f' d + k'^2 f' + 2\,k\,d\,b + b\,d^2 + f k^2 = \frac{125\,c^3}{3s} = m\,c^3$ by putting $m = \frac{125}{3s}$. From this equation we find

$$d^2 + \frac{2\,k' f' + 2\,k\,b}{b} \times d = \frac{mc^3 - 2\,k\,k' f' - k'^2 f' - k^2 f}{b};$$

Fig. 6.



A B $= d$ I H $= f'$
B H $= b$ H D $= k$
C E $= c$ FE $= k'$
K E $= f$.

$$k^2 + \frac{2\,b\,d + 2\,k' f'}{f}\,k = \frac{m\,c^3 - 2 f' d\,k' - f' k'^2 - b\,d^2}{f};$$

$$\text{and } k^2 + (2\,d + 2\,k)\,k' = \frac{mc^3 - 2\,bdk - f k^2 - b\,d^2}{f'}.$$

From these equations we find, by quadratics, the following general values for d, k and k'.

$$d = \sqrt{\frac{mc^3 - 2\,k\,k' f' - f' k'^2 - f k^2}{b} + \overline{\frac{k' f' + kb}{b}}^2} - \frac{k' f' + k\,b}{b} \quad (1).$$

$$k = \sqrt{\frac{mc^3 - 2\,d f' k' - f' k'^2 - bd^2}{f} + \overline{\frac{bd + k' f'}{f}}^2} - \frac{bd + k' f'}{f} \quad (2).$$

$$k' = \sqrt{\frac{mc^3 - 2\,bdk - f k^2 - bd^2}{f'} + \overline{d + k}^2} - d - k \quad (3).$$

When $f = f'$, as is generally the case in practice, we get by a simple reduction,

$$d = \sqrt{\frac{mc^3 - f \times (k + k'^2)}{b} + \overline{\frac{k' f + kb}{b}}^2} - \frac{k' f + kb}{b} \quad (4).$$

$$k = \sqrt{\frac{mc^3 - (2\,dk + k^2) f - bd^2}{b} + \overline{\frac{ba + k' f}{b}}^2} - \frac{bd + k' f}{b} \quad (5).$$

$$k' = \frac{mc^3 - (b - f) \times (d^2 + 2\,dk)}{b} - d - k \quad (6).$$

from which equations, by having any two of the widths a, k, and k' given, the other may be found.

Example 1.—Required the width of the main dam in Fig. 6, the depth of the water to be resisted being 30 feet, and the other dimensions as follows, viz. $f = f' = 17$ feet; $k = 7$ feet; $k' = 10$ feet; and $b = 33$ feet.

By equation (4) we have

$$d = \sqrt{\frac{\frac{125}{270} \times 30^3 - 17 \times 17^2}{33} + \overline{\frac{10 \times 17 + 10 \times 33}{33}}} - \frac{10 \times 17 + 7 \times 33}{33} = \sqrt{\frac{12{,}500 - 4913}{33} - \overline{\frac{401}{33}}^2} - \frac{401}{33} =$$

$\sqrt{229{\cdot}9 + 147{\cdot}6} = 12{\cdot}2 = \sqrt{377{\cdot}5} - 12{\cdot}2 = 19{\cdot}4 - 12{\cdot}2 = 7{\cdot}2$ ft. which nearly corresponds with the width of the principal dam in the coffer-dam used by Telford for building St. Katherine's docks, the other dimensions being taken from the transverse section given in the *Journal*, page 433, Vol. II.

Example 2.—Other dimensions remaining the same as in the last example, what is the value of k when d and k' are each equal to 7 ft.

From equation (5)

$$k = \sqrt{\frac{12,500 - 17 \times (2 \times 17 \times 7 + 7^2) - 33 \times 7^2}{17} + \left(\frac{7 \times 33 + 7 \times 17}{17}\right)^2} - \frac{7 \times 33 + 7 \times 17}{17} = \sqrt{\frac{12500 - 2499 - 1617}{17} + \frac{350}{17}} - \frac{350}{17} =$$

$$\sqrt{493 \cdot 2 + 424 \cdot 3} - 20 \cdot 6 = \sqrt{917 \cdot 5} - 20 \cdot 6 = 30 \cdot 3 - 20 \cdot 6 = 9 \cdot 7 \text{ feet.}$$

Example 3.—Other dimensions remaining the same as those in example 1, what is the value of k' when $d = 7$ feet and $k = 9$ feet?

From equation (6) we have $k' = \sqrt{\frac{12500 - 16 \times (7^2 + 126)}{17}} - 7$

$$- 9 = \sqrt{\frac{12,500 - 2800}{17}} - 16 = \sqrt{\frac{9700}{17}} - 16 = \sqrt{570 \cdot 6} - 16$$

$= 23 \cdot 9 - 16 = 7 \cdot 9$ feet.

When $f = f'$ and also $k = k'$, we find from equation (4) by a few easy reductions

$$d = \sqrt{\frac{m\,c^3}{b} + \left(\frac{(b - f)\,k}{b}\right)^2} - \frac{(f + b) \times k}{b} \qquad (7).$$

also from the general equation of equilibrium, $2\,k^2 f + 2\,k\,f\,d + k^2 f + 2\,k\,d\,b + b\,d^2 \times f\,k^2 = m\,c^3 = 4\,k^2 f + 2\,k\,f\,d + 2\,k\,d\,b + b\,d^2$, from which $k^2 + \frac{b\,d + d\,b}{2f}\,k = \frac{m\,c^3 - b\,d^2}{4f}$, and by quadratics,

$$k = \sqrt{\frac{m\,c^3}{4f} + \left(\frac{(b - f) \times d}{4f}\right)^2} - \frac{(b - f)\,d}{4f} \qquad (8).$$

Example 4.—Required the width of the main dam in fig. 6, the depth of water being 30 feet, and the other dimensions as follows, viz. $k' = k = 8$ feet, $f = f' = 15$ feet, and $b = 34$ feet.

From equation (7) $d = \sqrt{\frac{12,500}{34} + \left(\frac{(34 - 15)\,8}{34}\right)^2} - \frac{(34 + 15)\,8}{34}$

$$= \sqrt{\frac{12,500}{34} + \frac{23,104}{1156}} - \frac{392}{34} = \sqrt{367 \cdot 7 + 20} - 11 \cdot 5 = \sqrt{387 \cdot 7}$$

$- 11 \cdot 5 = 19 \cdot 7 - 11 \cdot 5 = 8 \cdot 2$ feet, the width required.

Example 5.—What is the value of $k = k'$ when the depth of water is 27 feet $f = 15$ feet, $b = 30$ feet, and $d = 6$ feet?

From equation (8) $k = \sqrt{\frac{\frac{125}{270} \times 27^3}{60} + \left(\frac{30 - 15 \times 6}{60}\right)^2} - \frac{45 \times 6}{60}$

$$= \sqrt{\frac{91,125}{600} + \frac{9}{4}} - 4 \cdot 5 = \sqrt{151 \cdot 9 + 2 \cdot 2} - 4 \cdot 5 = \sqrt{154 \cdot 1}$$

$- 4 \cdot 5 = 12 \cdot 4 - 45 = 7 \cdot 9.$

Example 6.—What width shall we adopt for the main dam, the depth of the water being 18 feet, when $k = k' = 5$ feet, $f = f' = 12$ feet, and $b = 21$ feet?

$$d = \sqrt{\frac{\frac{25}{270} = 18^3}{21} + \left(\frac{(21 - 12) \times 5}{21}\right)^2} + \frac{(21 + 12) \times 5}{21}$$

$$= \sqrt{\frac{2700}{21} + \frac{2025}{441}} - \frac{165}{21} = \sqrt{128 \cdot 6 + 4 \cdot 6} - 7 \cdot 9 = \sqrt{133 \cdot 2} - 7 \cdot 9$$

$= 3 \cdot 6$ feet, the width required. If $s = 80$ lbs., we would find $d = 4 \cdot 3$ feet; and if s was still farther reduced to 60 lbs., d would require to be increased to 6·1 feet.

It appears that the value of s in the foregoing formulæ greatly operates on the result in finding the width of the coffer-dam under its different forms. Unless where otherwise mentioned it has been taken at 90 lbs. in the examples given, but this value may be much reduced if water presses under the dam, and the reduction will be in proportion to the quantity of the bottom surface pressed upon, or exposed to the action of the water. As the construction of some forms of coffer-dams are more liable to admit water underneath than others, s may probably in such cases have to be reduced so low as 60 lbs.

The dimensions in the last example are nearly those of the coffer-dam used by *Semple* for constructing the piers of Essex Bridge, in Dublin, in 1753, the depth of water varying from 13 to 20 feet along the line of the coffer-dam. This coffer-dam deserves particular attention as being probably the first constructed in the kingdom, at that time, for such a depth of water; and from the difficulties the engineer had to encounter in the execution of the work, and overcoming one of the prejudices of the time then supported by the authority of a *Labylye*.

Figs. 7 and 8 show a plan and section of the coffer-dam taken from *Semple's Treatise of Building in Water*, which the author acknowledges to have taken from *Belidor's Hydraulic Architecture*. The

Fig. 7.

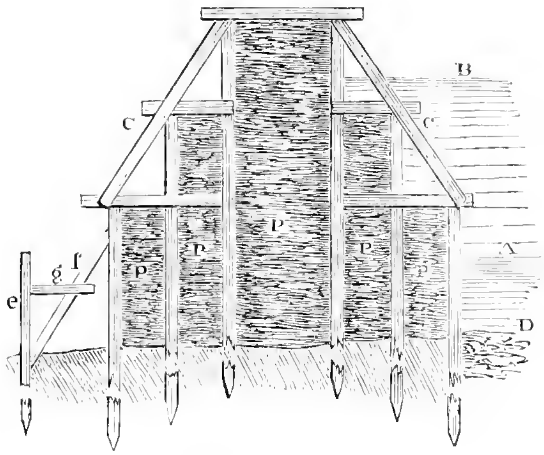


Fig. 8.

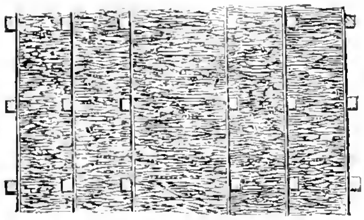


piles are about 6 inches square, placed at 4 feet apart along the line of the dam, and sheeted along the inside with, apparently, inch boarding. B high-water mark, A low-water mark, D bed of river, C C occasional braces, f, g, and e, auxiliary braces, and P pudling. The width between the sheeting from out to out is 15 feet, and the main dam is 5 feet wide. This construction is however far inferior to that of continuous sheet piling as adopted at St. Katherine's Docks, and at the New Houses of Parliament; as the resistance, offered by the depth of bed penetrated by the pileing, is trifling in the former plan compared with that in the latter, but on the other hand the quantity of timber employed is less in the former.

It may be necessary in conclusion, to remark that the depth of water ought to be taken from the surface to the bottom of the exposed coffer-dam, inside; for though that depth may not be on the outside, yet the water generally forces its way down so far; or if not, forces the bed with nearly an equivalent pressure against the coffer-dam.

Ancient Greek Manuscript.—An important discovery has been made by M. Didron, during his recent archæological tour in Greece and Turkey, of a Greek manuscript, about 900 years old, containing a complete code of religious monumental paintings. This document, found at Mount Athos, gives full instru tions concerning all the subjects and persons that ought to be painted in churches, with the age, costume, and attributes that each figure ought to have. A copy of this manuscript is making at Mount Athos with the greatest care. Another manuscript, containing a similar code on religious architecture, is believed by M. Didron to exist at Adrianople, and he has some hopes of obtaining it.—*French paper.*

LONDON AND WESTMINSTER BANK.

WITH AN ENGRAVING, PLATE VIII.

The accompanying engraving originally appeared in the *Atlas*, from which also we are enabled to give the following description of the building.

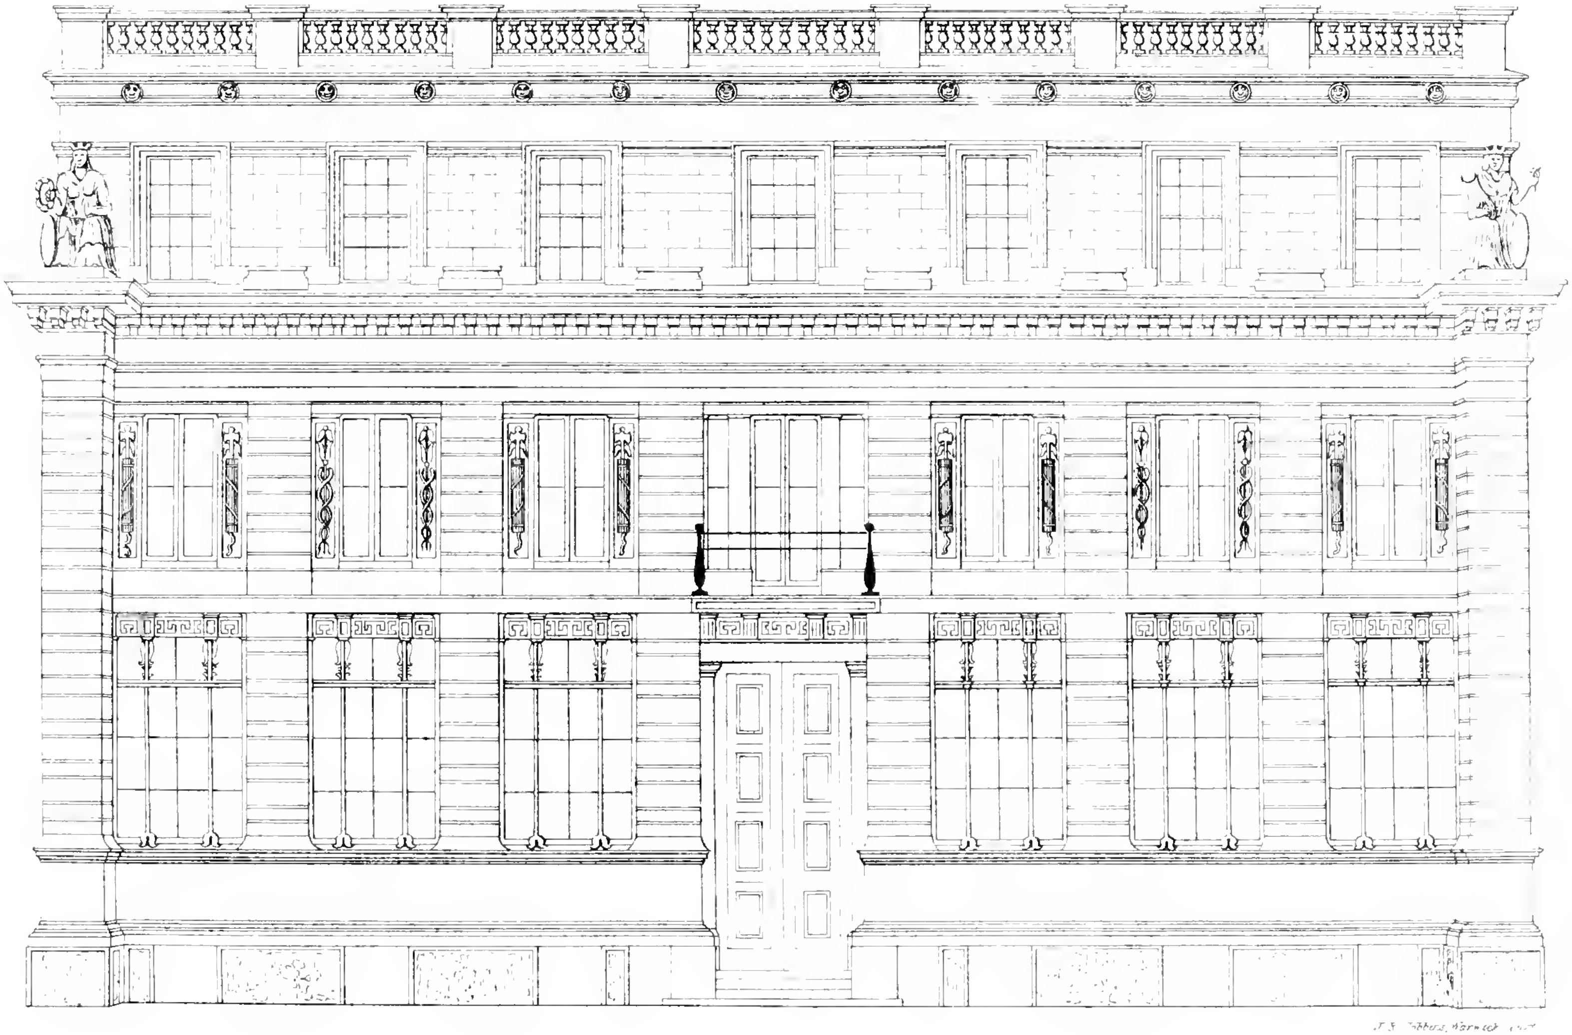
This new building for the city establishment of the London and Westminster Bank, which was completed in the latter part of 1838, under the joint professional superintendence of Mr. C. R. Cockerell and Mr. William Tite, architects, is situated in Lothbury, immediately opposite to the Bank of England. The whole structure occupies a site of nearly eighty feet in frontage, and ninety in depth. The entrance front possesses, not only from its extent, but from its architectural treatment, a bold and imposing character. It displays, indeed, no columnar decorations, no hundredth edition of an approved portico; but its composition has the much greater merit of strict appropriateness, simplicity in general forms; such simplicity, we mean, as conduces to unity, together with a perfect expression of purpose; an air of solidity and strength, and a judicious equality of decoration. The façade consists of one general plane or face, broke only by an advancing pier at each end. It has seven apertures in the length, and three tiers of them in the height; the two lower tiers, comprehending the openings on the ground and one-pair floors, are included in one architectural story, or order, if such it may be called; the upper tier, which consists of the windows of the two-pair floor, being contained in an attic story. The whole of the front is of Portland stone, with the exception of the plinth, which is from the Bramley-fall quarries. To describe the front rather more in detail, we may state that the substructure is a stylobate, or continuous pedestal, resting upon a deep rock-faced plinth. From this stylobate rise broad pilasters, or rusticated piers, in courses of alternate widths; the whole including, as we have said, two tiers of openings, and surmounted by a regular entablature, the cornice of which is enriched with modillions. Of the seven compartments into which the front is divided, the central one is somewhat wider than the rest, and displays, on the ground floor, a handsome entrance doorway of large proportions, and deeply recessed, approached by several steps externally, and having the flight continued within. The remaining intervals afford six large windows, each being so wide as to admit of subdivision by two mullions and a transum of cast iron, of elegant design and novel structure; the isolated mullion partaking of the character of an antique candelabrum at the base, and finishing with a scroll or console at the top: very wide and lofty Venetian windows are thus obtained, without affecting the real or the apparent solidity of the fabric, and the great and important problem (as applied to the City of London), namely, to obtain the largest possible admission of light, with the smallest obstruction of solids or piers, is most effectually, and, at the same time, architecturally attained. These windows are furnished with Bunnett and Corpe's iron shutters. The windows above, upon the one-pair story, are narrower than the former, and consequently leave, on each side between the rusticated piers, intervals available for decoration: these are sculptured alternately with caducei, the invariable commercial symbol, and with the bundle of sticks, expressive of the *vis unita fortior*, so appropriate to the union, or joint-stock association, of this establishment. In consequence of the advance of the two end piers in the principal order before-mentioned, there is gained in front of the attic story, which is not similarly broken, sufficient space for the display of two statues of seated female figures, emblematical of the commercial interests of London and Westminster, and having shields charged respectively with the arms of those cities; a mode of applying statuary to the purposes of external decoration, enlivening and appropriate to the general structure, and effective as regards the proper development of the subjects themselves. These figures are designed (and one of them—that of London—we understand to have been modelled) by Mr. Cockerell, and executed by Mr. Nicholl.

But it is time that we pass to the notice of the interior. The entrance vestibule or avenue has, on each side, a line of four plain Doric columns, with appropriate entablature and decorative mouldings. Its effect is, however, unavoidably impaired by the interference of two pairs of screen doors, though these are panelled and surrounded with plate glass, to obviate the objection as far as possible. From this ample vestibule, access is gained on the right to the country bank, the principal staircase, and some official apartments; and, directly in front, to the principal, or town bank. The latter apartment is not only by far the most considerable in the building, but is unequalled in importance by anything of the kind in London, except in the case of some offices of the Bank of England, and in altitude it exceeds even them. Its general form is a square of about 37 feet, whose height is that of the entire building—namely, 59 feet 6—and is extended by lateral additions, east and west, to a portion of this height. These additions or aisles are divided from the centre, on each side, by an arcade of three arches, springing from Doric columns of the same size and order with those of the vestibule, with cornices. The columns themselves, in common with all the other features of the design, display a sober and subdued style of decoration or enrichment, being fluted only at the upper and lower extremities, and elevated upon plain flat plinths. The surrounding walls are channelled in rustic courses to the height of this order. The aisles or extensions are sufficiently lofty, by the arches raised upon the columns, to allow of the introduction of a gallery on each side, finished in front by a balustrade. Above this, the arches of the arcades run across over the aisles, and are intersected by a contrary vaulting, producing a system of groins as ceilings to the galleries; they are also advanced over the main body of the building, and treated as a series of half groins, so as to afford support to an upper projecting gallery, which passes quite round the principal square. The verge of this upper gallery is guarded by a simple, but handsome barrier, consisting of a double horizontal rail, sustained at intervals by ornaments of scroll foliage. Over this gallery the lines of the cubical form below are continued through, and gathered up, by means of pendentives, into a domed figure, exhibiting nearly that portion of a hemisphere cut off by planes raised upon the sides of a square inscribed within its circumference. The top of this dome is pierced by a large circular opening for a skylight, the margin of which is covered, and additionally ornamented with mouldings and lions' masks. Light is also obtained by triple windows, occupying the flat semicircular spaces left by the pendentives of the dome, on the three sides which are exposed to the view of a person entering, in the manner of the imperial Roman baths: these windows are filled with glass in geometrical compartments, alternately ground and polished. Smaller semicircular windows are introduced likewise in the three arches on the north side, which form a continuation to those of the lateral arcades, so that a very sufficient light has been contrived throughout this vast apartment, surrounded as it is with lofty and close buildings on all sides. Such is a general description of this apartment, the composition of which displays considerable novelty of adaptation, magnitude of proportions, and felicity of effect. The general forms are very happily diversified, and the decorative details distributed with equality; except, indeed, that the eye would have welcomed the application of some enrichment to the large expanse of the dome, which is left entirely plain. The fittings up are in a style of appropriate completeness; comprising handsomely finished and extensive ranges of counters; a massive central stove, of consistent design, being a bee-hive, round which the arms of London and Westminster, and the guardian of British commerce, as well as of goverment—the lion—are ranged with taste and propriety; an hydraulic apparatus, by which plate chests and cash boxes may be lowered into the basement story for security, or brought up with great facility, and other minor appurtenances.

RAMBLES BY PHILOMUSÆUS.—No. V.

THE BRITISH MUSEUM.

After this establishment has been partially closed for months, its directors have felt themselves compelled to show the public that at least they have not run away with the collections. They still keep the long gallery closed, and have thrown open two new galleries, in which a few unnamed articles are placed in undescribable confusion. We have seen representations of the plunder of a wreck by a crowd of savages, one with a pair of breeches in his arms, another with a coat matted round his waist, running from one package to another, ransacking their contents, and then throwing them about in confusion, and such is the state of the Museum. Egyptian coffins in one place, Etruscan tombs in another, all in most admirable disorder, the passages choked up, the rooms encumbered, and packages covered with the dust of months, accusing the inefficiency of the officers of the establishment. Nothing, perhaps, more nearly resembles the Spectator's description of a monkey in an Egyptian temple, ranging about not knowing what to do, and then establishing himself in a corner. That this institution has the active services of many men of the highest ability we fully recognize; we do not complain that there are not enough men of talent, we only call for the employment of more routine-working men. We are sure there are numbers of young men, sufficiently qualified, who, for a small remuneration, and many indeed for none at all, who would, under the superintendence of the officers, be competent to assist in the classification, without requiring a permanent employment in the establishment. We know that there is a great want of room, that the architectural department is sadly cramped,



THE LONDON & WESTMINSTER BANK

but we are convinced, notwithstanding, that there is a want of energy on the part of the officers, which throws the business into arrear, and paralyses the whole operations.

The Long Gallery has now been closed nearly a year, and the public thus shut out from the Portrait Gallery, the geological and mineralogical collections. At the same time we know that Dr. Mantell's collection of nearly thirty thousand specimens has been purchased, and ought long since to have been arranged. The Etruscan collection has remained in its present state during the whole of the last year, and thus has it been rendered totally useless. The Egyptian collection is, on the lowest estimate, two years in arrear, and the Vase Room good for nothing. As to the mammalia, their condition has been a subject of ridicule many years, and every month, by increasing the collection, renders the absurdity but more manifest. The managers of this department certainly deserve the highest praise for their compressive power, in which, doubtless, they have hardly yet met with a rival. An old bachelor's travelling portmanteau is nothing to it; cats crouching under lions, deer striding over wolves, the cases, crammed even into the crevices with stuffed animals, show a crowd of imprisoned and confused creatures, which even the ark of Noah could not equal.

With regard to what has been done, it has been little indeed. The arrangement of the Ægina marbles has been completed, the Phidian and Phigalian Saloons have been painted of a red granite colour, which, it is to be wished, may be continued throughout the whole house. The collection of fish, saurians, and batrachians, has been extended, and the insects and corallines removed. At Paris, a much greater number of entomological specimens is exhibited to the public, and so far is the respect even for vulgar curiosity carried, that the whole of the papilionaceous tribes are shown, forming a sight of natural beauty which is well calculated to strike the spectator with emotion. It is a national disgrace, that, ruling over one hundred and forty millions in India, we have no good collection of oriental objects, the illustration of our own antiquities is equally defective, and many departments flourishing in countries of less resources, are here totally neglected.

As to the catalogues of public collections in this country, with the exception of a portion of that of the British Museum relating to natural history, they are miserably defective, and inferior to what is done abroad. The catalogue of the National Gallery is a gross imposition, charging one shilling for a book which contains about one pennyworth of print and paper, and scarcely one farthing's worth of information. The catalogue of the Louvre, although necessarily restricted, gives much more detail, the name of the painter, of his master, the period at which he lived, the school to which he belonged, and a description of the subject. That of the National Gallery gives the name of the painter, and the date of his birth, and only the name of the picture, giving such references to the people as to a story in Tasso, and limiting the descriptive matter to a history of the picture, which, as many of the works are spurious or contemptible, is of no value. The catalogue of the antiquities in the British Museum is of no use, either to the artist or the public, giving the name of the statue, and barely that! No—a Mithraic subject! Who knows what that means, or who can tell where to find out. The catalogue of the Paris Museum of Antiquities, under the same circumstances, gives a page or two of small type to an account of the Mithraic rites. That catalogue gives, in every case, the name of the subject, extent of mutilations or restorations, history, stone of which made, height and breadth, and a full antiquarian and artistical account, with reference to the authorities of any peculiarity to be observed in the statue. To such an extent is this carried, that the catalogue is a complete encyclopædia of Greek and Roman costume, having the author's name attached to it, and invaluable to the student.

THE PUBLIC WALKS OF LONDON.

Much is said about the public gardens and walks of Paris, nothing is said of those of London, except by foreigners whom they never fail to strike with admiration. The Tuileries, the Champs Elysées, the Luxemburg, the Jardin des Plantes, and the Quais have great and incontestable merits, they possess features which we cannot rival, but those of London again are unexcelled in their own department. Each style is suited to its respective nation, perhaps it is a consequence of their several characters, perhaps a cause. We see at once the Frenchman in the classic statues, in the ordonnanced foliage, the imprisoned orange trees, and the straight walks. The Englishman seems to impress his own character in the grassy slopes, luxuriant timber, and placid waters of the scenes in which he epitomizes his beloved isle. The Frenchman knows no paradise without artifice, the Englishman none without nature, the American hates even the sight of a tree. That of which we have to complain is neither the grandeur nor extent of our public walks, but their unequal distribution. The parks were truly named the lungs of the metropolis, they are so, to the overworked mechanic they are receivers from which he obtains fresh breath to carry on his life-shortening labours. Yet as in the human being if we had an unequal distribution of the respiratory organs, we should find an atrophy of the body, so in the immense metropolis an insufficient provision of these necessaries of life causes an immense loss of human existence. The southern portions of the metropolis between Greenwich and Kew are miserably unprovided, but it is among the impoverished population of the east that the want is felt in all its severity. So great indeed is the difference between the average value of life in the east and the west of the metropolis, that whereas in the latter it is 2·1 per cent., in the former it is 3·2, and in Whitechapel it is so low that one female in twenty-four dies in a year, an awful mortality, scarcely perhaps equalled by Portugal or any other misgoverned country.

The walks of London may be divided into two classes, public and corporate, and the former again into special promenades and into thoroughfares and micellaneous sites used for this purpose.

Among the special promenades are to be reckoned St. James's Park, collection of curious birds, military monuments and music; Green Park; Hyde Park, military exercises and Kensington Gardens, military music; Regent's Park; Greenwich Park; Kew Gardens; Draper's Gardens, Throgmorton-street; Artillery Ground, City Road, military music; Tower Hill, recently planted; Lambeth Walk; Cheyne Walk, &c.

Among the other places used for walks are the old commons and greens as Islington and Kennington; Chelsea Hospital; the Cemeteries at Kensall Green, Highgate and Norwood; the Docks, &c.

We have not a line of Quais as at Paris, and we should be sorry indeed if we had, but we have points on the river affording unrivalled views:—the Dock Wharfs, Tower Wharf, Custom-house Wharf, Temple Gardens, Waterloo Bridge, the Adelphi Terrace, Hungerford Stairs, Millbank, Cheyne Walk, the Bishop's Walk (Lambeth), and the Terrace of Greenwich Palace.

Coming to the second class walks belonging to and used by communities, we have the unrivalled squares, the gardens of Lincoln's Inn, Gray's Inn, the Temple, Charterhouse, &c.

These many establishments place London almost without a rival in the provision for this department of public health, and in the beauty of many of the establishments and their accessaries, as well as in the splendour of the views which they afford,—unique prospects of one of the largest cities and ports in the world.

GOVERNMENT MEASURES FOR STEAM VESSELS.

It was with regret that we learned that on the first day of the session the government gave notice of their intention to bring in a bill for carrying out the recommendations of the Steam Vessel Inquiry Commission. This report has now been long published, and so far from attracting the support of those who have examined it, it has excited either open hostility or silent contempt. We had occasion on its appearance to call the attention of our readers to its provisions, we pointed out the meanness and paltriness of the means by which it was attempted to be supported, and the injurious results which must infallibly ensue from the enactment of its provisions. A case of grosser jobbery, or more iniquitous misrepresentation than is presented by the report was never hardly brought before the public. Had indeed the necessity of inquiry been so great as to require investigation only to ascertain the extent of injury, a case would at once exist for the appointment of a commission, but when no such necessity existed, when no evils prominently called for redress, it was but a gross mockery of public credulity, and an arbitrary exercise of delegated power to invest men of whatever standing with authority, which they received as it were with permission to direct for their own personal advantage. What was it but calling on the commissioners to make out a case not only to justify their present employment, but to give them occupation for the future, to do as they have done in this case, to use every artifice of an accuser to overwhelm the object of pursuit? Has even common respect been paid to the judgment of the public, common justice been shown to the victims of this persecution? facts of trivial insignificance have been overrated and overstated, a judicial investigation has resorted to absurdities to bolster up a false cause, popular prejudices have been appealed to, insufficient and untried examples have been enforced as of authority and example, in fine the dignity of the government and the people has been outraged, the prosperity of the country threatened, and the vested interests of property attacked. And for what purposes but the grossest? To furnish new places at the expense of the best interests of the country, to subject the genius of its inventors and the characters of its manufacturers to an inspection more servile than degrades even a French police; to stifle ingenuity, to give a monopoly to ignorance and indolence, to cripple the energies of the nation, and in striking at one branch, to prepare a chain for all.

We have on previous occasions exposed the misrepresentations and fallacies of this report with an unsparing hand, and therefore refrain from enforcing on our readers arguments, of the truth of which they are well persuaded. We may observe that admitting all the statements of the commissioners to their fullest extent, they are but arguing from the abuse against the use, they are seeking to upset the great principles of English administrations, and to foist in foreign degradations; they are endeavouring to substitute for the grand principle of protecting the mass against the errors of a few, that of sacrificing the whole body to correct trifling abuses, a system which while it is being abandoned abroad, is endeavoured for the first time to be introduced here. Founding their claims upon untried or inefficient precedents, they call for powers greater than even these examples authorize, and make up by boldness of demand for the weakness of their cause. They rely upon the examples of the United States and of France, they dare to bring forward that of Belgium, they conceal that other circumstances prevail in the States, that the laws of France are inefficient and unobserved, and that Belgium has no vessels for which to legislate.

This measure ought not to be, cannot be, carried; its results are too evidently mischievous to allow us to believe that the parties affected can be so deaf to their own welfare as to allow it to be carried into effect without resistance. We call upon them, therefore, to unite, to meet together and concert measures for the defeat of a project so odious and so ruinous; it is only by union that this can be effected; it is thus the aggressions of government have been successfully resisted by the railways and other interests. We earnestly advise, therefore, that immediate steps should be taken for calling a meeting of the boat-builders, engine-makers, and steam-boat captains, and of all those who have property embarked in this large and increasing branch of the shipping interests.

THE STATUE OF HUSKISSON.

By John Gibson, R. A.

[We are indebted for this able paper to the kindness of our eminent and talented correspondent at Rome, whose love of art is only equalled by his knowledge of it.—Editor.]

We have much pleasure in announcing that Mr. Gibson is engaged in executing another statue of Huskisson, which, we understand, is to be placed in the Custom-house, at Liverpool. This statue differs in some respects from the former one executed some time ago, in as much as that, the attitude is different, and we think that it is more dignified, and seems to breathe the true Attic spirit of a great orator, both statues however partake of the character of the Demosthenes of the Vatican, and the Aristides* of Naples. The latter was so famous that Demosthenes accused his rival Eschines of imitating it, or an antique statue that resembled the Aristides, by folding his arm in his pallium when he addressed the public from the rostrum.

As the former statue of Huskisson was sacrificed from the fact of its having been placed in a temple of too small dimensions, we therefore shall offer a few observations, lest the one we now are about to describe should share the same fate. The first statue was composed in such a manner as to allow of its being seen in any point of view, and it necessarily followed, that the temple should have been of that magnitude, to have enabled a spectator to have encompassed with his eye the entire figure on walking at a sufficient distance around it, whereas it was found necessary to place it with its back to the wall. Thus it is that the skill of the sculptor displayed in the composition has been miserably defeated by the ignorance of the architect; in consequence of which the statue can only be seen in one point of view, and that, the most unfavourable, remaining enshrined in stone, hid from vulgar eyes, like the oracle of Delphi. The height of the statue should have given the architect the scale of proportions for his temple. Arrian's description of the Pontus Eurinus, says that the statues and images placed in a sacred edifice should always be in proportion to it, as being a part of it. "Quod enim ad membra sacrarum ædium etiam statuæ earum atque imagines pertineant, docet nos Arrianus in ipso statim invitio peripli ponti Euxini." The proportions of temples with regard to the statues which were to be placed in them was strictly observed by the ancients. The Emperor Adrian objects to the statues of Mercury and Philesius in the temple of Trapesuntia, as being less than the just proportions which the temple required. "Ibi enim Adrianum Imper: certiorem facit Mercurii ac Philesii statuas in Trapesuntiorum templo minores esse, quam pro ipsius templi ratis debeant." Bad artists place small statues upon large pedestals, thus showing their own ignorance. Vitruvius says* all the parts of a sacred edifice must agree in each single part with the general height of the whole.

Trusting this second statue will not share the same fate, we will now proceed to describe it. The statue, like the first one, is colossal, Huskisson is represented standing in an easy and dignified attitude, the right leg a little advanced, his arms are naked, and the left one is raised towards his face, whilst the right arm hangs by his side, and in the hand he holds a scroll. The breast is naked, while the drapery falls within a short distance of his feet, and is brought over the left shoulder. The attitude is becoming the senatorial dignity of a great statesman, and is at once quiet and impressive; from the stern and meditative air it might be almost imagined that he was about to summon up to his bidding all the resources of his gigantic mind, and that he had grown a colossus in power,—that Demosthenic eloquence was about to burst from his lips. The head which we believe is a faithful portrait, has all the artistical attributes which are indicative of genius, approaching to the beau ideal of a philosopher, the expression of the face is severe, and the features are vigorously pronounced, the cold marble is made to breathe with a soul, nay almost with human intelligence. The nude is true to nature, yet all traces of mechanical art and vulgar impurities have been effaced by the magic touches of a chisel directed by the master hand of another Phidias, it has made the marble start into immortal life. The entire figure would seem to have been cast in that mould in which the Greeks were wont to form their heroes and their gods. The drapery is consonant with the subject, masterlike in style, easy and flowing, it is in fact the Greek pallium, consequently classic, and hence suitable to assist at the apotheosis of a great statesman. Huskisson like another Aristides,† has now had a statue raised to his memory for having caused by his eloquence the embellishment of that city which gave him political fame during life, and immortality after death. He is fortunate too in having for his artist a fellow-citizen so distinguished. In the drapery of Gibson's figure we find that it is disposed with judgment, while the skill shown in the arrangement of the folds gives a rich effect, and the harmony of the lines serve to preserve a proper balance of light and shade. We also remark that the angular creases, and the spirited touches of the details contribute to the grand effect of the whole. To arrange drapery is one of the most difficult branches of the art, sculpture cannot as in a painting, imitate the nature of the stuff, and give the various shades of colour which have their origin from the reflection of light and shade.

Quatremere de Quincy observes, "that ancient clothing is employed by art, not as ancient but as natural, not because it was adopted by the Greeks and Romans, but because no other can be employed in imitation; and further not even so much because it is accordant with the metaphorical style, as because the modern costume is anti-imitative. This being the case, the interest of every nation requires that in confiding to the sculptor the task of perpetuating its exploits, and its great men, it should watch over the taste and the style of imitation in works, which while they inspire respect for the images so enshrined, may bear favourable testimony to future ages of the period at which they were upraised."

No reasoning can be stronger than this, and we think the observations of the above cited learned author irrefutable, but we will repeat that the modern style of dress is wholly inconsistent, and quite unworthy of the dignity of sculpture, and we shall find that whenever it has been attempted, whatsoever might have been the style of dress of the period, classic taste has been outraged and every principle violated which is the characteristic of beauty in art. The object of sculpture is not to give an individual portrait dressed up in the whimsical or the ephemeral fashion of a day, but to perpetuate the memory of persons by investing the lasting marble with the attributes of that classic style of art, which has been handed down to us by those whose works yet stand omnipotent, and have outlived the wreck of time. Sculptural portraiture in fine was considered by the Greeks and Romans as a convention, at once allegorical and imaginary, sometimes it represented the metamorphosis of the gods, or the apotheoses of princes, warriors, orators, poets, and philosophers. The statues of

* From some very recent discoveries we believe that this statue called Aristides, is Eschines himself.

* Vitruvius, lib. 3, cap. 3.

† When Smyrna was destroyed by an earthquake, Aristides wrote a letter so pathetic to M. Aurelius that he ordered the city to be immediately rebuilt, for which intercession a statue was in consequence raised to the orator.

Alexander, Adrian and Antinous are naked, and were made ideal gods, they like the statue of Pompey, seem to have a mystic life, there is a very language in those cold, stern, and colourless stones, which breathes an air of truth and creates on our minds more interest than their names in the pages of history. The statue of Napoleon,* by Canova, is naked, and is an apotheosis; it is confessedly, grand, imperial, and collossal; it has immortalized the hero, as well as the artist, and when we consider that Canova and Gibson were the first to set so good an example to their country, we must say that their statues will ever stand pre-eminent over the barbarous objects which disfigure some of our public monuments.

We would ask is there a person capable of reflecting who has paced the vast sculpture gallery at Versailles, and not smiled at the absurd dresses of some of the marble effigies; in days gone by they were admired, and the persons they represented were doubtless, much venerated, but alas! how changed, they now excite our contempt, and we feel inclined to laugh outright at their antiquated costumes. The time will come, and it is not far distant, when the vagaries of our sculptors will share the same fate, and become also objects of ridicule. It is an opinion held by some artists that all monuments should have the figures executed in the style of dress of the period in which they were erected, but we feel sorry to observe that it is only interested and inferior artists who advocate this opinion, and it is because they find that to model drapery and the naked proportions is excessively difficult, and often beyond their capacity, they are therefore contented to please the ignorant multitude, who for the most part, like the cobbler could only criticise the sole of the shoe in the picture of Apelles, for which reason persist in perpetuating the fame of our generals and admirals in all the glorious absurdity of modern tailory—epaulets and cocked hats, boots and spurs. Of what possible consequence can it be to us that antiquarians should discover in after times that pig-tails were commonly worn in the reign of George the Third? and moreover, that it was a most singular custom with their ancestors to represent great warriors in a mutilated state, having only one arm, and sometimes wooden legs. This they would conjecture was done to bring to the recollection of the public that they had lost their limbs in the service of their country. Lest the time may arrive when even the name of a Nelson should be blotted out of the page of history, we would recommend that his amputated arm be placed by his side, to convince future ages that he was once a perfect being, and furthermore to satisfy the public who ever crave after monstrosities,† the arms and legs of his brave comrades might be piled up in a group as monumental trophies of their valour! Non eadem miramur!!

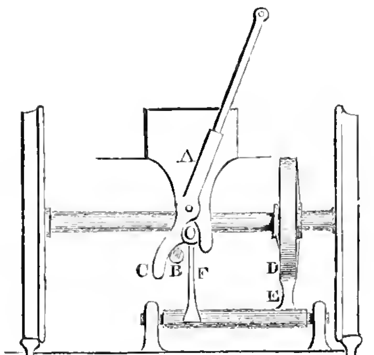
FELAGRIO.

Rome, January 18, 1840.

DIOGENES'S SELF-ACTING GROUND-ROPE APPARATUS,

FOR TAKING UP THE ROPE.

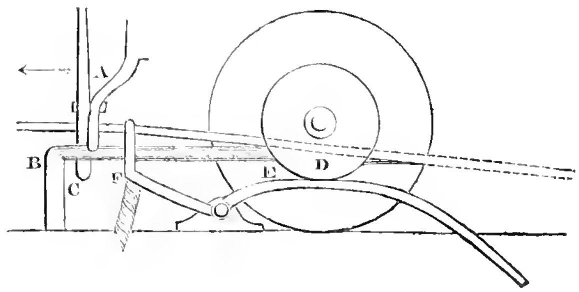
Front View.

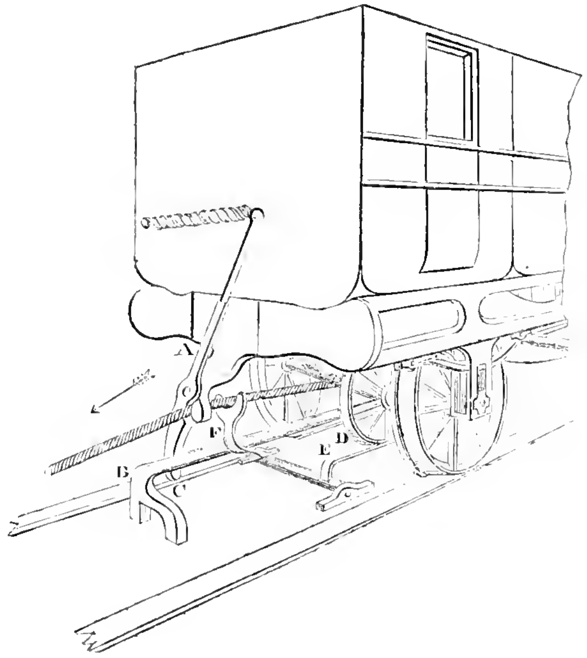


* This fine statue of Napoleon is in the possession of his Grace the Duke of Wellington, at Apsley-house.—ED.

† We have *dogmatical* proofs that the French have outgeneralled us in sculptural atrocities, for in the triumphal arch of Napoleon at Marseilles, there are *poodle-dogs*, and a whole legion of amputated *arms and legs*.

Side View.





REFERENCE TO THE LETTERS.

A Claws or holder for the rope.
B Bar for forcing open the claws, in order to liberate the rope, or previous to taking hold of it.
C Lower part of claws, which works against the bar B.
D Small wheel fixed upon fore axle of carriage to elevate the fork.
E Lever over which the wheel D passes, and forces it down.
F Fork fixed on the same axle as the lever just mentioned; but by being on the opposite side, it is raised as the lever is depressed; it is pulled down again by a spring It is to raise the rope to the level of the claws; were the claws fixed lower, they would catch against the pullies. It should be observed that the fork is not raised until the claws have passed it. The rope is liberated by a similar bar, only the fork for lifting up the rope is omitted.

THE EPICYCLOIDAL STEAM ENGINE.

[We have given this communication at the request of some of our readers, although it is not new, as we stated in our notice to correspondents. The motion will be found described in the second volume of Gregory's Mechanics, and the author there states that it was introduced in an engine erected at Bermondsey. It may be seen as we before stated at the Saw Mills in the Arsenal at Woolwich.]—ED.

SIR—I am happy to communicate my improvement on the steam engine.

In all engines now employed the motion of the piston rod is communicated by a connecting rod to the crank. This rod, by the nature of the motion always works obliquely. The obliquity of action is certainly objectionable, as it evidently occasions a loss of power.

Accordingly, the connecting rod is always made as long as may be, within limits fixed by other circumstances, for thereby the obliquity of its action is diminished. A method of communicating the motion of the piston to the crank, without loss of power by such a cause, has therefore been a *desideratum.*

The fundamental principle of my contrivance is, that the epicycloid generated by any point of the circumference of a circle rolling on the interior of the circumference of another circle of twice its diameter, is a straight line, the same point always describing the same straight line. Thus, the circle A B F, fig. 1, rolling on the circle A C A', in the above-mentioned circumstances, any point, A in it, moves up and down A A', a diameter of the larger circle. It is easily inferred too, that the centre E, of the inner circle describes a circle E G, of equal radius concentric with the larger circle; so that, were E and F connected, the connection E F would move round F, in the manner of a crank.

Fig. 1.

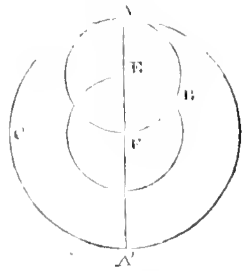


Fig. 2.

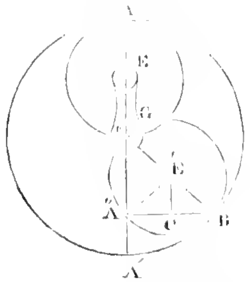


Now, let A A' and A F, fig. 2, be the primitive diameters of two teethed wheels, in which the teeth of the larger one on the interior of the circumference, and those of the smaller on its exterior, so that they may run into each other. Let G be the extremity of a shaft concentric with the wheel A A', and carrying a crank G E, of which the pin at E is also concentric with the smaller wheel A F. Then, when G revolves, it carries the wheel A F with it, which runs on the crank pin, its teeth at the same time taking into those of the wheel A A', and the point A of the wheel A F describing the path A A'. Reversing the mode of action, suppose the large wheel to be fixed; then if the piston rod of a steam cylinder of which the stroke is equal to A A', be jointed to a pin standing on the primitive circumference of A F at A, for example, the machine, with a fly on the shaft G, will work, so as that this shaft will have a continous rotatory motion.

In this method there is neither connecting rod nor parallel motion. The piston rod is connected immediately with the pin on the wheel A F, and is led up and down rectilineally by the very nature of the motions.

Now, the fact that no special parallel motion is required, proves that none of the power is wastefully exerted. To be more minute, however, suppose the crank in the position F E', fig. 2, A' A'' will be the piston rod, jointed at A'' to the wheel. Producing F E to B, this will be the touching point of the two circles. Draw A'' B, A'' E', and drop the perpendicular E' C upon A'' B. Then A'' E' B must be considered as a crooked lever of the second kind, in which B is the fulcrum, and E' and A'' respectively, the points of application of the resistance and power. Now, in the triangles F E' A'', A'' E' B, the angle $E' F A'' + E' A'' F$ (or 2 $E' A'' F$, 5.1. Euclid) = 2 right angles — $F E' A''$; and $E' A'' B + E' B A''$ (or 2 $E' A'' B$, 5.1. Euclid) = 2 right angles — $A'' E' B$ (32. 1. Euclid). And taking the half sum of these equations, we have $E A F + E A B$ = 2 right angles — ($F E' A'' + A'' E'' B$) = 1 right angle, that is, A'' B is perpendicular to A' A'', and therefore, A'' B is the leverage of the power acing in the line A' A''. C B is also the leverage of the resistance acting in the line E' C; and it is easily seen that A B = 2 C B; so that, as this demonstration applies in every position of the crank, putting the angle A'' F B' = Z, and F B = 1, we conclude, in general, that,

1. The leverage of the power $= \sin. Z$;

2. resistance $= \dfrac{\sin. Z}{2}$;

3. The line of action on the crank is always parallel to the piston rod. Now, as could easily be proved, by this mode of action, namely, the parallelism of the impulse on the crank, the whole power of the piston is communicated to the main shaft; and thus is my object proved to be attained.

Besides the advantage already stated, this engine possesses two others, simplicity of construction, and smallness of bulk. It differs from the common ones in this also, that with the same sweep of crank, it has twice the length of stroke; and accordingly, as we see from the above two fixed conclusions, the leverage of the power is twice that of the resistance.

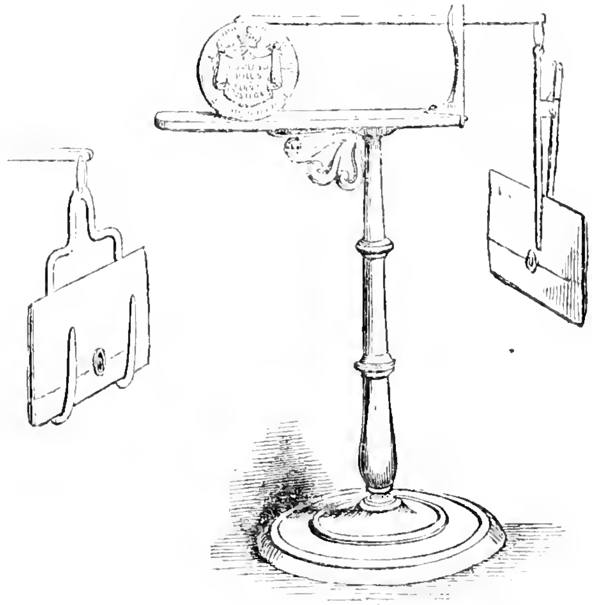
I am, Sir, your obliged servant,

Daniel Clark.

Glasgow, Dec. 19, 1839.

HOOPER'S POST OFFICE LETTER WEIGHTS.

The accompanying engraving represents one of Hooper's peculiar letter balances, the merits of which are its simplicity and accuracy; a grain in effect would turn the balance either way. Although numerous devices have been introduced for this purpose, none that we have seen surpass this in utility, in which it is as much before its competitors, as it was in priority of introduction.



THE FITZWILLIAM MUSEUM.

The Fitzwilliam Syndicate have reported to the Senate:

"That Mr. Basevi has certified to the Vice-Chancellor that Mr. Baker has executed works in the building of the Fitzwilliam Museum to the value of £34,000 or thereabouts; and Mr. Basevi has thereupon recommended that a sum of £5,000 be now paid to Mr. Baker on account of the said works in addition to the sum of £25,500 already paid to him on that account.

"That although the above-mentioned sum of £5,000 exceeds the instalment which Mr. Baker is at present entitled to demand according to the terms of the contract: the Syndics, under the circumstances stated in Mr. Basevi's certificate and letter, beg leave to recommend to the Senate that the said sum be paid to Mr. Baker, provided that he is willing to agree that the balance to be retained by the Vice-Chancellor until six months after Mr. Basevi shall have duly certified the entire completion of the works, shall according to the terms of the contract, be not less than 10 per cent. upon the whole amount of the contract; and that Mr. Baker's sureties are willing to agree that the payment of the sum of £5,000, as above proposed, shall not affect or impair their present liability under the contract."

The Syndics further recommend;

"That Mr. Basevi be authorized to order the execution at a cost not exceeding £1,000, of certain works at the Fitzwilliam Museum not included in Mr. Baker's contract; it being advisable that such works should be completed previously to making any further contracts for the finishing of the building.

R. Tatham, *Vice-Chancellor.*

W. French. G. Peacock.
G. Ainslie. J. Haviland.
J. Graham. H. Philpott."

At the Congregation this day, a Grace will be offered to the Senate to confirm the above Report.

* Mr. Basevi's certificate and letter will be laid on the Registrar's table.—*Cambridge Advertiser.*

EXPLANATION OF SOME TECHNICAL TERMS USED IN STEAM ENGINE CALCULATIONS,

WITH REMARKS ON THE CORNISH QUESTION.

Sir—The full and satisfactory account you have given in your February number, of the new engine at the East London Water-works, must not only be highly interesting to those of your readers who are attached to pursuits connected with the steam-engine, but also to those who value truth for its own sake, inasmuch as it will very soon settle the long-disputed Cornish question, besides being of the greatest practical importance to the proprietor of mines and other large works in all parts of the kingdom.

It now appears that in my comparison of the Cornish and Lancashire systems in your number for January, I had, as indeed I wished to do, rather over than under-rated the power of the engine above referred to, and when I have all the data for going into the commercial part of the question—the comparative expense—I am afraid it will be found that the advantage of the Cornish system has been somewhat more largely overrated by others, especially with reference to the propriety of adopting that system in cotton factories. At any rate, when the proper corrections are made in my table of comparative duty, from the statement you have furnished, I think no one will be found to contend that *four, five*, and even *six* times more work (as has been often asserted) is performed by the steam-engines in Cornwall than in the north of England for the same quantity of fuel of like quality. Indeed, the excessive degree of perfection hitherto claimed for the Cornish engine is much to be regretted, even if true, as it carries a certain degree of absurdity on the face of it, that has not a little indisposed engineers on both sides of the question to a fair and dispassionate inquiry. With a view to expedite the settlement of the most important parts of the question, and prevent that divergence from the main point at issue which is liable to occur with the best-intentioned disputants, I have made the following attempt to define certain technical terms which prevail in this district, and it will be of use, perhaps, to some engineers both in and out of Cornwall. I am also induced to submit these definitions to the approval of your readers, because I observe, in Mr. Enys' remarks in your last number, a few slight misconceptions of my meaning, which, together with perhaps a want of strict accuracy of application in some of the expressions used by me, have led that gentleman to underrate the comparative duty of the Lancashire engine; there are also errors in his statement that go to the disparagement of the *Cornish* system, which I am sure must be quite obvious to that gentleman, as well as the rest of your readers, on the slightest reconsideration of the subject—I more particularly allude to the concluding portion of Mr. Enys' communication. No guess work allowances are at all requisite either for "vacuum imperfections" or engine friction and resistance in my estimate of the Lancashire engine, as the load on the piston of 10 lbs. per circular inch was not the calculated, but the *observed*, steam pressure taken by the indicator, as I distinctly stated, and it of course includes the friction of the engine, shafting, &c. The average steam pressure acting on the piston of the pumping-engine, was, on the other hand, not observed, but *calculated* to be 10·65 lbs. per circular inch, which would be the difference of pressure between one side of the piston and the other, due to the given load on the other end of the beam, including of course a small allowance for the friction of the engine itself, as was required to render it equivalent to the indicator pressure; but no allowance was required in this case, any more than in the other, for "vacuum imperfections." I purposely chose this method of avoiding the risk of making erroneous deductions from what I think is properly termed the "gross horse power," so that a more just comparison of the two systems might be obtained. Possibly some allowance may be required for pit-work friction, but as Mr. Enys seems to think that nearly equivalent to deficient water delivery, the omission cannot make much difference.

From the corrected data now given by Mr. Wicksteed, it appears that the load in the shaft, 66,443 lbs. must be reduced for the leverage of the beam in the proportion of 10 ft. 3 in. to 9 ft., or to 58,398 lbs. and this sum, *plus* an allowance for friction, is the gross load in the cylinder, instead of 68,160 lbs., which I had before assumed from the data then furnished to me. The proper substitutions corresponding to this correction being made in my table of "Comparative Duty," it will be seen that the latter will be materially altered in favour of the Lancashire system.

For the purpose already stated, and also in order that a clear understanding of the meaning intended to be conveyed in future, when comparing the power or economy of steam engines, it seems necessary that some technical terms commonly used by engineers and others should be strictly defined. The following are definitions of such as are used in reference to the power of the factory or cotton mill engine; and I trust that some of our Cornish friends will favour us with a similar elucidation of the equivalent terms that obtain in Cornwall, such as "duty, efficiency, &c."

The "*nominal power*" is what an engine is called by its maker, and Mr. Watt's standard, it is well known, was that due to an effective pressure of steam in the cylinder of 6 lbs. per circular inch, and a speed of 220 ft. a minute for each horse power. The "*gross power*" is the total power exerted by the steam in the cylinder, including that required to work the engine itself, or to overcome what are called the friction and resistances of the engine, and is equivalent to the whole force of the steam acting on the piston against a vacuum more or less perfect; or, in other words, it is the force resulting from the average difference of pressure between one side of the piston and the other; this average is that obtained by the indicator, and it is in general sufficiently correct for all practical purposes. The indicator pressure, it will be observed requires no correction or allowance for what are called vacuum imperfections, such allowance only being required when, for want of indicator experiments, the steam pressure in the cylinder can only be estimated from that in the boiler. The "*effective power*" is the total power exerted by the engine, or delivered at the crank shaft, after overcoming its own friction. This friction, of course, not only includes the friction, properly so called, of the piston, pump buckets, stuffing boxes, &c., as well as all the bearing parts of the engine, but it also includes the resistances due to the water lifted by the engine pumps, and is a quantity that varies in different engines according to the different degrees of excellence in their workmanship, situation, and other circumstances. In general it is found to be equal to from one to two pounds per circular inch on the area of the piston in the best modern engines, but in a much less ratio in large engines than small ones. When an engine can be unconnected with the shafting, its own friction can be readily ascertained by the indicator; this, however, would only be what M. Pambour properly calls the "*unloaded* friction," for, of course, the friction of nearly all the bearing parts of the engine must increase with the load in some ratio corresponding to the goodness of workmanship. This *loaded* friction is variously estimated by different engineers, at from one fifth to three tenths of the gross load; and Tredgold estimates it at about ·238 of the whole of the force of the steam in the boiler, or with the resistance to the steam in the passages, the loss of power by cooling, &c., included, he calls it ·368 of that force (see Tredgold, new edition, page 196). Although the unloaded friction of the engine, when the speed of the latter admits of being easily regulated, is capable of correct ascertainment, as I have already stated, yet it is rarely so obtained in factory engines separately from the friction of the shafting; but when so obtained and deducted from the gross power, the result gives a certain amount larger than the real effective power, by so much as the loaded exceeds the unloaded friction of the engine. This result has been proposed to be termed the "effective *indicated* power."

The "*net effective power*," or available power of an engine, is usually understood to be the power delivered at the machine pulleys, or that which is effective or available in turning the machinery, exclusive of that required to turn the shafting, the straps, and the loose pulleys. The friction of the shafting, when ascertained by the indicator, (the machine straps being thrown on the loose pulleys) is of course the unloaded friction, and as in the case of the unloaded engine friction when deducted from the effective power, leaves a result for net effective power somewhat greater than the truth; this result, however, has been proposed to be denominated the "net effective *indicated* power." This last is what is meant when the number of horses power required to turn any given portion of machinery is said to be ascertained by the indicator. It is always understood to include so much of the friction of the engine and shafting as is due to the increased load, and is commonly, and I think properly, termed the "*indicated horse power of the machinery*." It is also sometimes called "available" power, but evidently without due consideration, that term being only strictly applicable when used to signify the net effective power, and which may be ascertained in many cases independent of indicator experiments.

Should it meet with your approbation, I shall be glad to furnish you with practical illustrations of the above remarks by indicator, diagrams, and calculations taken from engines now at work in this county, previous to going farther into the consideration of the question of the *economy* of the Cornish system.

I am, Sir,
Your obedient servant,
R. Armstrong.

STEAM APPARATUS.

Sir—Having had my attention drawn to the notice of my drying machine in your Journal of this month, page 28, and conceiving that your editorial remarks is calculated to withdraw attention from it, I beg to trouble you with the following explanation :—

The application of steam heat to the purposes of drying is very common, as every one knows; but, in all cases that I am acquainted with, its *direct* application is *to the air* in which the goods intended to be dried are exposed —that is, they are hung up in a heated air. Ventilation is essentially necessary in every operation of drying; but the ventilation which carries off the moisture evaporated from the wet goods, carries off also, a portion of the heated air before it is *saturated* with moisture. There is, therefore, a waste of caloric, or heat, in all systems of drying with which I am acquainted. My object has been to avoid this—to prevent any particle of caloric generated from escaping without performing its duty. The mode adopted in this machine, is not to heat the air, but to hang the drying goods close to the pipes which generate the heat, and in such a manner as shall form an entire sheet, *closing in* and *covering* the pipes. In this case it is evident that no heat can escape *without passing through the wet goods*, for the heat is on one side only of the drying material, which on the other side is a current of air which carries off the moisture as fast as it is expelled. It is by this economy of heat that we are enabled to dry 150 sheets in an hour in the small machine at Abingdon.

The principle may perhaps be better understood by any one acquainted with the common mode of drying woollen clothes in stoves. It is well known that the usual length of a piece of cloth is about 40 yards, and that the rack on which it is hung in a stove is *doubled* in two parallel lines 6 or 7 inches apart, to avoid an extreme length of building. The cloth when hung is stretched on this rack, so forming a double line with an interval of 6 or 7 inches; into this interval or between the double rack, pipes are introduced, the top of the interval being closed by a piece of board connecting the double rack.

It is thus clear that the heat generated from the pipes can escape only *by passing through the cloth.* So effectual is this mode found in the extensive manufactories of Messrs. Wilkins and Co., near Bath, that a cloth which used to be four hours in drying, is now dried in three quarters of an hour, while the fuel is diminished two parts out of three. It follows also, of course, that from the rapidity of the changes, one-fourth of the space formerly required is now sufficient.

As applied to the drying of wool the same advantage is discernable. In this case the pipes are laid under a perforated floor, and the wool so disposed that the ascending heat *may pass through it.* By this means two rooms are found to dry more than was formerly done in six.

I am, Sir, your obedient servant,

James Wapshare.

A PARISH CHURCH BURIED IN THE SAND FOR 700 YEARS, LATELY DISCOVERED.

(From the Churchman.)

Of the many objects to which the attention of your readers is drawn, in the various departments of your paper, there is not one which can exceed in interest the following account of the church of Perranzabuloe, or St. Peran, in the hundred of Pydar, in the county of Cornwall. For more than seven hundred years it had been imbedded in the sand, from which it was rescued, in the year 1835, by the persevering exertions of a private gentleman, William Mitchell, Esq., of Compregny near Truro; and there are many considerations which render a description of the church, in the state in which it was found, very opportune and seasonable at this moment; for its present state affords presumptive and internal evidence of the fallacy of some of those pretensions in which the members of the Romish communion indulge, as to the antiquity of the church, and the pomp and splendour of their services. It would be no difficult matter to prove, by authentic documents, that the first three centuries furnish not the slightest authority for those pompous ceremonies, and those puerile observances which were introduced, and which still continue to outrage the simplicity of the primitive worship. With respect to this particular church, the sand has been accumulating for many hundred years, but when completely removed, the church was found in the most perfect state; and it is a very singular circumstance, that the interior contained none of the modern innovations and accompaniments of a Romish place of worship, from which the evidence is clear and indisputable, that it must have been built at a period anterior to the introduction of the numerous corruptions, &c., of the Papistical communion, and gives sanction to the well authenticated fact, that, in the first three or four centuries, not one of those puerilities and observances, borrowed either from Pagan idolatries or the Jewish ritual, were known; for the truth is, what we see in Romish places of worship, is nothing but a transfer of what we read from the synagogues of the Jews, or the temples of the Pagans; and which outvie in particular, in splendour and magnificence, the sacerdotal vestments with which those were apparelled who officiated either in the one or the other. The whole of their service is an appeal more to the external sense, than an address to the understanding and the affections. There was no rood left for the hanging of the host, nor the vain display of fabricated relics, no latticed confessional, no sacring bell (a bell rung before and at the elevation of the host,) no daubed and decorated images of the Virgin Mary or of Saints, nothing which indicates the unscriptural adoration of the water, or the no less unscriptural masses for the dead. The most diligent search was made for beads and rosaries—pyxes and Agni Dei—censers and crucifixes. Strange that this ancient church, in which it will be borne in mind, everything was found as perfect as at the time in which it was first imbedded, should so belie the constant appeal to *antiquity*—to the *faith* of their *forefathers*—to the *old religion*, as it is falsely termed, as if that were religion which has not a particle of the simplicity and purity of the primitive church, to sanctify and identify it as a branch from the true apostolical tree! At the eastern end, in a plain, unornamental chancel, stands a very neat but simple stone altar, and in the nave of the church are stone seats, of the like simple construction, attached to the western, northern, and southern walls. With such humble accommodations were our fathers, who worshipped God, in simplicity and truth, content!

From the amiable and intelligent historian of the past and present condition of Perranzabuloe—the Rev. C. T. Collins Trelawny, a descendant, on the maternal side, of the good Bishop Trelawny—a name of which he may well be proud—one of the seven of the glorious company who preferred the gloom of a prison before submission to the mandates of an arbitrary papistical tyrant,—I have had an interesting letter, in which, in answer to my inquiry as to the present state of the parish church, he informs me that it is not in a condition to admit of its being used for any purpose whatsoever, as it is already again entombed in the sand! It was with extreme regret that I received this communication; for so much had my interest been excited by Mr. Trelawny's narrative, which is beautiful and will well repay many a perusal, that I was on the point of fulfilling arrangements I had made for a summer visit to the venerated spot; but I hope that the same enterprising spirit by which it was five years since resuscitated as it were, and recalled into being, will be again interposed to rescue it from its present entombment, and be a temple yet appropriated to the service of the living God! I know not the localities; but who in such a wish does not join? and where is the man whose piety would not grow warm as he worshipped within the hallowed pile of Perranzabuloe, as much as it would within the mouldering ruins of Iona? It may not, perhaps, be unimportant and uninteresting to add, that the tutelar Saint of Cornwall was Peranus, or St. Perran, after whom the imbedded church was named, and that the memory of this saint is still cherished with fond veneration by the people of Cornwall. His annual commemoration is celebrated on the 5th of March. Christianity was first preached in Cornwall by Corantinus, by whom the whole of the population was rescued from Pagan idolatry, and converted to the Christian faith, at the end of the third, and at the commencement of the fourth century.

James Rudge, D.D.

Hawkchurch Rectory, 18th Dec. 1839.

ARCHITECTURE AT HOME AND ABROAD.

[We select the following remarks on architecture from an interesting paper which appeared in the last *Foreign Quarterly Review.*]

Owing to the great impulse which has been given to building, since the peace, we have now, throughout the country, a show of very respectable bits of architecture—things of rather ambiguous or negative merit;—Gothic made neat, Grecian made homely, Italian softened down to insipidity. In art our ambition is of a staid, modest, and reasonable kind. Among all our recent works we have few of monumental character, that is, such as testify honourably to the power and taste of the age in which they were produced: scarcely any thing that is really imposing in point of scale, and not less imposing and dignified in style. Our classical school is mechanically correct, frigid, an mannered: we must not look to it for geniality of conception, masterly originality, or happiness of invention. What beauties it gives us are almost altogether borrowed;—transcripts of good originals as regards individual features, which are, however, seldom more than merely put together, instead of being so combined as to produce an ensemble with one and the same spirit pervading every part, a kindred feeling diffusing itself throughout. Owing to an unfortunate littleness and feebleness of manner, buildings large in themselves do not make an impression at all proportionate to their size, but are reduced to the minimum of effect. For grandeur and majesty of aspect Buckingham Palace will hardly bear comparison with that lately erected at Brunswick; and which though by no means unexceptionable, proves Ottmer to be as superior to Nash, as Brunswick is inferior to Great Britain. What the former looks like, or rather does not look like, we all know too well; but the other has a princely air that bespeaks the residence of a sovereign.

Contrasts of this kind are likely to pass for invidious, more especially when they happen to be unfavourable to ourselves; yet the best way of preventing such is by taking a salutary lesson from them for the future, and endeavouring to be first where we now stand almost last. If, however, only to show that we wish to be impartial, and do not blindly defer to the authority of names and reputations, we shall here bestow some notice on the Königsbau, or new palace at Munich, numerous plans and other engravings of which may be seen in the Bauzeitung for 1837. We need scarcely disavow any prejudice *against* Klenze, for we have been charged with being much too favourably disposed towards him our comments, therefore stand a chance of being received as free from bias either way.

The principal, or indeed, only façade, namely, that forming the north side of the Max-Josephs-Platz, extends in a perfectly unbroken line for the length of 406 feet (English). It is 65 feet high, except in the centre, where the height is increased to 95 by the addition of another order, for the extent of eleven windows, or somewhat more than half the length of the front: there being twenty-one windows or apertures in each of the other stories. So far there are the elements of grandeur—length, continuity, loftiness; and when we add to these, massiveness, both with regard to the relative proportion of solid and void, and that arising from the character of the style employed, namely, the older Florentine, it will be taken for granted that it is not at all deficient in greatness of character and the qualities allied to it. Nevertheless we are dissatisfied, less for what it is than for what it is not. Scarcely any pretension whatever is made to originality; the whole is too direct and close an imitation of the Palazzo Pitti; the character also is palpably borrowed and assumed, with this additional drawback of being altogether exotic, and not at all in unison with anything else. As a monument, the original is a highly interesting and impressive work of architecture; as a study, most valuable; as a model, most unfit,—that is, for a palace in the nineteenth century. Recourse might have been had to the same style, but it ought we conceive, to have been differently treated,—in many respects considerably modified; and required a livelier and more captivating expression imparted to it. Instead of this, the physiognomy given to the edifice is by far too repulsive and stern: simplicity has been carried to severity, uniformity pushed to monotony, and to the exclusion of play or contrast of any kind. Moreover, its close general resemblance to the Palazzo Pitti is apt to provoke a disadvantageous comparison, because after all it falls considerably short of that edifice in its mass; at the same time that it is deficient in the powerful contrast produced in the other by the greater solidity there of the lower part. We do not approve of architectural duplicates, more especially when an opportunity offers for a masterly and original production. Such opportunities are far too precious to be negligently thrown away, and ought to be turned to account by creating something that shall carry art onward, and, if possible, give it a new and invigorating impulse.

These objections are no way diminished when we discover that instead of the façade preparing us for the interior, it is quite in opposition to it; the decorations throughout the latter, both architectural and pictorial, being scrupulously, not to say affectedly, Grecian, both in style and character. By Wiegmann, Klenze has been reproached with inconsistency for having in the Glyptotheca employed vaulted ceilings and other forms of Roman architecture within a building externally professing to be purely Grecian:—this, we must say, savours rather of hypercriticism. But in the case before us there is a positive clashing of opposites, because though the apartments are in every other respect perfectly Greek in style and taste, their circular-headed windows contradict it, and disagreeably remind the spectator of the still more decided difference between the taste of the exterior and that of the interior. This, however, is a trivial blemish compared with one very serious and pervading efect; namely, that of the plan altogether, which so far from presenting any kind of beauty, any originality, contrivance, variety, contrast, or play, is exceedingly commonplace and monotonous, and is inconvenient withal as can well be imagined. It is divided on each floor into two enfilades of rooms, all rectangular, either square or oblong, without any intermediate communication, except one part where there is a narrow passage for domestics. As far as arrangement goes, not the slightest attempt has been made at effect. Not only are the principal rooms nearly of the same form, but nearly all of the same size, and so disposed as to occasion inconvenience, and exclude effect also. This will hardly be disputed when we say that the centre of the enfilade in the front of the building divides into a series of small rooms, having only a single window each; and being appropriated as the king's and queen's bed-rooms, dressing-rooms, &c., entirely cut off all communication between those on either side of them. Thus, so far from any climax being produced, all sort of focus and centralization is destroyed, and the parts are disunited and scattered. In fact the whole of this floor can be considered as consisting only of private apartments, notwithstanding that both on the king's and queen's side there is a throne-room preceded by two or three ante-chambers. With the exception of the rooms at either extremity of the front, all the others must be inaccessible to those whose immediate personal attendance on their majesties does not give them the privilege of passing and repassing as there may be occasion of doing.

We will not be quite sure that fresco-painting, when employed to the extent which it is throughout Munich palace, is altogether the very best mode of decoration, or calculated to give the greatest importance to the architecture. For particular rooms and in certain situations, it may be suitable enough; but it is hardly so for sitting rooms, where paintings upon such a scale are apt to become too obstrusive, and by their subjects forming too harsh a contrast—sometimes perhaps almost a ludicrous antithesis—to the familiar details of social life: the opposition becomes that of poetry to prose. A mere picture does not force itself so conspicuously upon the attention; it may be gazed at or not, studied or overlooked; but paintings which constitute, so to say, the local scenery of the whole space, put forth a too direct claim to notice; and though they may be interesting to the casual visitor, cease to make so much impression after constant familiarity. A great deal may certainly be said on both sides; we shall therefore only observe that as decorations for the walls of sitting rooms, subjects in fresco ought, we conceive, to be employed with some reserve, and not suffered to occupy too great a space of surface. In this opinion we are borne out by one who must be admitted a competent authority on the subject, and who has not scrupled to question the propriety of some of the most noted works of the kind. "The far-famed Loggie of the Vatican," says Hessemer, "which ever since they first existed, have been extolled as the greatest models of decoration, are in fact not decoration at all, but a series of paintings covering the surface of both walls and ceilings. As a whole they possess no architectural character; and if the separate pictures, allegories, &c., have very little intimate connection with each other, they have, as such, still less with their situation and with the building itself. As offering an instance of the greatest contradiction between locality and decoration, may be mentioned the works of Giulio Romano in the *Palazzo del Te* at Mantua, with regard to the pictorial but *non-decorative* merits of which I forbear to make any further comments."

After our animadversions upon the Königsbau we can hardly be charged with being indiscriminate partisans of the "Bavarian Ictinus;" nor is it without concern we are compelled to admit that the talents of Klenze have not always been in proportion to the opportunity afforded, or in correspondence with the generous ardour of his royal patron. For the faults we have pointed out we are not indebted to his opponent Wiegmann: since he bestows no notice on any of Klenze's buildings, except merely *en passant*, with brief and general censure, and without entering at all into particular criticism. So far his pamphlet has disappointed us, for though the title makes no specific promise, we did expect that, whether for eulogy or the reverse it would furnish —if not a biography, yet something like an account of the architect's professional career. Instead of this, the writer confines himself almost entirely to the consideration of Klenze's principles and theory, as illustrated in his collection of designs for churches, entitled "Christiche Bauart." Of that production we cannot trust ourselves to speak, not having the volume by us to refer to, nor now recollecting more of it—after a single inspection—than that we considered the designs of rather mediocre quality, and betraying a want of study. The specimens there given of Greek architecture as applied to that class of buildings appeared to us by no means happy models, nor calculated to no trace, as they might have done, had the motives of each subject been explained. As little are we able to say whether the severity of Wiegmann's remarks,—his fastidiousness and captiousness are justified by anything he himself has done, or by greater success attending his own principles; to confess the truth, it is not very clear to us what the latter really are, or what at times he means to say. We may however venture to assert that several of his remarks come home to others besides Klenze, and who, equally bigotted in favour of Greek architecture, are still more cold and pedantic in their application of it; formal copyists, who do not even attempt more than a mere reflection of the antique, and that only in particular features; and while certain forms are scrupulously imitated, fidelity as to the genius and real spirit of the style affected is usually lost,—perhaps held matter of no account. The consequence is that the things so produced are more of less failures—neither antique nor modern—not a skilful adaptation of both, but a harsh and disagreeable conflict of opposing elements and contradictory ideas. Little does it avail for an architect to exhibit the most perfect Grecian portico or colonnade, if he at the same time lets us see that he has trusted to that alone;—that so far from being a necessary portion of his structure, it is a mere adjunct which, though certainly not so intended, chiefly forces us to feel its own vast superiority over all the rest; and the difficulty, if not impossibility, of making that which ought to be principle harmonize with, or even seem worthy of, what is engrafted upon it. Almost invariably do architects forget that by such adoptions they tacitly bind themselves to raise every other part in the same spirit, and to display such powers as shall excuse their appropriating the merit of others to themselves, by making it truly part and parcel of their own work.

Unless this last can be effected with ability, the antique forms will seldom be more than something hung about a modern building,—extraneous parts;—not a consistent dress in which the whole is attired, but mere trimmings and appendages; intended to pass for architectural style, but oftener making it all the more manifest, how deficient the building itself is in character, and destitute of all that conduces to style. Nay, if, on the one hand, columns and other Greek decorations display the great superiority of classical taste, on the other, they lose much of their original value and charm, by being associated with what but ill accords with them. Many a modern soi-disant Greek building reminds us of Cicero's witty question to Lentulus: "Who has tied you to that great sword?"—for with us the question might frequently be: Who has tied that plain and insignificant building to that classical portico?—It also generally happens that such feature is itself impoverished, in order that the contrast between it and the rest may not be too ridiculously glaring.

Diametrically opposed to Klenze, who considers Grecian or Greco-Roman architecture—for he does not reject the Roman arch—to be the only style adapted for universal application, Wiegmann contends that the adherence, or the attempt to adhere, to pure Greek forms in our present and totally different system of construction, is no better than pedantic affectation; and that they ought no longer to be retained by us as models. He further asserts that there can be no such thing as a permanent and unchangeable style in architecture, and that the endeavour to revive at the present day any by-gone style whatever is an absurdity, and very much like trying to force a stream to flow back to its source. According to him, only that which is perfect matter of indifference in itself, and has nothing to do with style, can be indiscriminately adopted as suitable to all times and all occasions. In this there is a certain degree of truth, but somewhat of perverseness also; for a style based upon Greek architecture must upon the whole be allowed to run more in unison with modern taste generally, and prove more capable of application to every diversity of purpose, than any other we are acquainted with. At all events Wiegmann himself has not even attempted to point out how we are to extricate ourselves from the perplexities of his doctrine. He is not one of those who would discard Grecian in order to make way for Gothic, because he rejects the one just as much as the other. Neither do we exactly know how far he really objects to the Greek style, or under what limitations he considers its adoption allowable or even beneficial. That he admits the latter to be possible, is, however, apparent from the commendations he bestows upon Schinkel, observing:

"He is an inspired venerator of Grecian art: but instead of adhering to its externals alone,—to what was more or less conventional in it, and arose out of the circumstances of the times in which it flourished—he has actually penetrated into its very spirit, and in more than one of his works has shown that the rationality and beauty arising out of construction,—which stamps the works of the Greeks as superior to all others, may be made to display themselves even at the present day; and that notwithstanding the great difference between them and the structures of antiquity in regard to many particulars of design, such works partake infinitely more of the same spirit than do the ill understood and lifeless imitations of which Klenze has furnished us so many," viz. in his Christliche Baukunst.

How the above passage can be very well reconciled with the apparently unqualified rejection of Greek architecture even as a type for us moderns, is a point we must leave to Herr Wiegmann himself to explain. In admitting that it is possible to catch the true spirit and genius of Grecian architecture, and to infuse them into buildings adapted to widely different purposes from those of antiquity, he admits that all we ourselves contend for; and in fact, so far advocates the very course we ourselves would uphold;—since few can be more strongly opposed than ourselves to that cold, formal, lifeless imitation of Greek models, which amounts to nothing more than the most servile and tasteless species of copying,—slavishly correct as to certain particulars, but egregiously incorrect—absolutely licentious, in all that regards taste and feeling. We certainly should have been far better satisfied had Wiegmann explained himself so fully as to remove all apparent contradictions, and to leave no room whatever for doubt; still more, had he confined himself more strictly to architecture, instead of entering into vague metaphysical inquiries with regard to the nature and power of art generally, while he is so brief and obscure in regard to many points connected with the former, and which it is highly desirable that either he or some one else should render perfectly clear. What he chiefly proves is, not that Grecian architecture is altogether inapplicable at the present day—such doctrine being wholly at variance with the very high commendation bestowed upon Schinkel for the happiness with which he has in many instances made use of it;—but that the designs in the Christliche Baukunst are nearly all more or less defective, notwithstanding that they were put put forth as models for the instruction of others, nor was their author at all fettered in his ideas by any of those circumstances which generally interfere in the case of actual buildings. After all, therefore, the more important question is left poised in equilibrium, as much being conceded on one hand as is denied on the other. Very little notice, again, is bestowed on the buildings actually erected by Klenze, notwithstanding that many of them—not only the Pinacotheca and Neue Residenz, but Prince Maximilian's Palace, Kriegsministerium, Post Office, &c., are almost entirely in the Italian and particularly in the Florentine style; yet whether the Munich architect's practice is on that account to be considered much more sound than his theory, we are not explicitly told, but left to guess it as well as we can. Now this indistinctness and indecision are to us highly disagreeable: if Wiegmann thought he could even demolish Klenze altogether and give the death-blow to his theory in recommendation of Greek architecture, he should have shown himself more in earnest; and instead of saying a very great deal that amounts to nothing, should have stuck to the main point, and there battered away. If he wishes to have it understood that Klenze is little better than a charlatan in art, he should have put—or tried to put the fact beyond doubt,—should have left us no middle course, but have either compelled us to adopt, or called upon us to refute his arguments.

We are, indeed, favoured with opinions as to one or two of the structures erected by Klenze at Munich; yet mere opinions are very different from argument and criticism: they may be correct or erroneous, just or unjust, but, if received at all, must be taken entirely upon trust, at least by those who have either not the means, or else not the ability, judging for themselves. Thus, Wiegmann dispatches the Königsbau very summarily, calling it a "verballhornten Pallast Pitti;" and again, condemns the Glyptotheca as an unhappy combination of a pure Greek temple with a prison-like mass of building. If it is the absence of windows that constitutes the prison-like character complained of, the same comparison may be extended not only to the temples, but almost all the other public edifices of the ancients, that are remaining; while if some other circumstance produces this effect, it might not have been amiss to explain it to us. Is Wiegmann of opinion that the wings of the façade are too low for the portico?—that, instead of rising above the rest, the portico would have appeared more of a piece with it, if merely stuck on to the building, and made to jut out from it, the whole front being kept of the same height throughout? Or does he think that some windows both within the portico and on each side of it would have improved the whole,—have mitigated the too temple-like character of the one, and the too prison-like aspect of the other? This is what he does not care to inform us; neither does he afford the least clue as to what he considers a more harmonious combination, by referring to something else as an example of it. The most therefore, that we can say in his excuse is, that he is kept in countenance b a great many others who seem to think that the mere expression of praise or blame is sufficient for architectural criticism.

This last remark applies far more strongly than we could wish to the Allgemeine Bauzeitung, where of the various buildings that have been represented and described, scarcely one has had any comments made upon it. Yet this suppression of criticism can hardly have been occasioned by overstrained delicacy, because several would have afforded opportunity for descanting upon the merits of their design. Among these are the Buchhändler Börse at Leipsic, erected by Geutebrüch, the architect of the Augusteum, 1834-6; and Dr. Härtel's house in the same city, by Waldemar Herrmann of Dresden. Both are in a rich Italian style; and of the two the latter has somewhat the superiority as to extent of façade, its front being 112 feet (English), in length, while that of the other is 108. Besides which it has very much the air of a public building, as there is only a principal floor with an open Corinthian loggia of five intercolumns, above the ground-floor or basement, while the loggia itself is decorated with compartments in fresco. As far as style and beauty of external architecture go, there is scarcely a private mansion in all London that can compete with it, certainly not one of recent date; for even Sutherland House is but a very plain and frigid piece of design in comparison; and both Norfolk House in St. James's Square, and Buckingham House, Pall Mall, are absolutely homely. To say the truth, it may fairly challenge almost any one of our Clubhouses,—at least of those already erected,—for we must not as yet include the Reform Club, whose façade promises to eclipse all its neighbours. We call attention to this example all the more, because we have nothing similar at home: on the contrary, so far from any stimulus having been given of late years to architectural display in the town residences of our nobility and persons of fortune, it would rather seem that the trumpery show and flaring tawdriness of the Terraces in the Regent's Park, and other barrack-like ranges of buildings of that class, have brought the system into disrepute; and it certainly must be acknowledged that the plain and perfectly unassuming brick fronts of houses far more costly and spacious than those just alluded to, have a far more aristocratic look than the others, whose grandeur is nothing more than overgrown littleness, and meanness tricked out in the coarsest finery: truly they may be described as the very Brummagem of architecture.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL SOCIETY.

Dec. 19.—Major Sabine, R.A. V.P., in the chair.

A paper was read, entitled,

"*An Account of Experiments made with the view of ascertaining the Possibility of obtaining a Spark before the Circuit of the Voltaic Battery is Completed*," by J. P. Gassiot, Esq.

The author of this paper adverts to the fact, of a spark invariably appearing when the circuit of the voltaic battery is completed; an effect which Dr Faraday has shown can be easily produced, even with a single series. He then refers to the experiments of Mr. Children, Sir Humphry Davy, and Prof. Daniell, recorded in the Philosophical Transactions; in which experiments, when more powerful and extended series were used, the spark was obtained before contact took place. In order to ascertain, not only the fact of a spark being obtained, but also the distance through which it may be passed, the author had an instrument prepared, which he denominates a *Micrometer Electrometer*, and by which an appreciable space of one five-thousandth of an inch could be measured with great accuracy. He describes this instrument; and relates several experiments which he made with a view to test the correctness of its action. He first prepared 160, and then 320 series of the constant battery, in half-pint porcelain cells, excited with solutions of sulphate of copper and muriate of soda; but although the effects, after the contact had been completed, were exceedingly brilliant, not the slightest spark could be obtained. He was equally unsuccessful with a water battery of 150 series, each series being placed in a quart glass vessel: and also with a water battery belonging to Prof. Daniell, consisting of 1,020 series; but when a Leyden battery of nine jars was introduced into the circuit of the latter, sparks passed to the extent, in one instance, of six five-thousandths of an inch. The author mentions his having been present at the experiment of Prof. Daniell, on the 16th of February, 1839, when that gentleman had 70 series of his large constant battery in action; and having been witness of the powerful effects obtained by this apparatus, he was induced to prepare 100 series of precisely the same dimensions, and similarly placed: but although this powerful apparatus was used under every advantage, and the other effects produced were in every respect in accordance with the extent of the elements employed, still no spark could be obtained, until the circuit was completed; *even a single fold* of a silk handkerchief, or a piece of dry tissue paper, was sufficient to insulate the power of a battery, which, after the circuit had been once completed, fused titanium, and heated 16 feet 4 inches of No. 20 platinum wire. The author then describes a series of experiments made with induced currents. 1,220 iron wires, each insulated by resin, were bent into the form of a horse-shoe. A primary wire of 115 feet, and a secondary of 2,268 feet, were wound round the iron wires. With this arrangement he obtained a direct spark (through the secondary current), sufficient to pierce paper, to charge a Leyden jar, &c. Several forms of apparatus employed by the author are next described, and also a series of 10,000 of Jacobone's piles. With this arrangement he charged a Leyden battery to a considerable degree of intensity, and obtained direct sparks of three-fiftieths of an inch in length. He ultimately succeeded in obtaining chemical decompositions of a solution of iodine and potassium: the iodine appearing at the end composed of the black oxide of manganese.

Jan. 9.—J. W. Lubbock, Esq., V.P. and Treasurer, in the chair.

A paper was read, entitled,

"*On the Construction and Use of Single Achromatic Eye-Pieces, and their Superiority to the Double Eye-Piece of Huyghens.*" By the Rev. J. B. Reade, M. A.

The author observes, that experience has shown it to be impracticable to make a telescope even approach to achromatism by employing the same object-glass with an astronomical, as with a terrestial eye-piece; for if the focus of the blue rays from the object-glass be thrown forwards, as it must be, in order to make it impinge upon the focus of the blue rays upon the terrestrial eye-glass, then there will be produced a great *over-correction* for the astronomical eye-glass, and *vice versâ*. Hence it appears that the application of Huyghenian eye-pieces to refracting telescopes are incompatible with the conditions of achromatism throughout the entire range of magnifying power: and that, in reflecting telescopes, they are incompetent to correct dispersion, because they are not in themselves achromatic. These defects the author proposes wholly to obviate by substituting, for the Huyghenian eye-pieces, single achromatic lenses of corresponding magnifying power, consisting of the well-known combination of the crown, and its correcting flint lens, having their adjacent surfaces cemented together; thus avoiding internal reflections, and enabling them to act as a single lens. The achromatic eye-pieces which he uses were made by Messrs. Tully & Ross, and are of the description usually termed *single cemented triples.*

"*Meteorological Observations made between October*, 1837, *and April*, 1839, *at Alten in Finmarken.* By Mr. S. H. Thomas. Chief Mining Agent at the Alten Copper Works; presented by J. R. Crowe, Esq., H. B M. Consul at Finmarken; communicated by Major E, Sabine, R. A. V. P. This memoir consists of tables of daily observations on the barometer and thermometer, taken at 9 A.M., 2 P.M., and 9 P.M., with remarks on the state of the weather at Kaafjord, in lat. 69° 58′ 3″ N., and long. 23° 43′ 10″ E. of Paris.

J. Whatman, Jun,, Esq., was elected a Fellow.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Jan. 20.—Edward Blore, V.P., in the Chair.

A paper was read,

"*On the History of Græco-Russian Ecclesiastical Architecture.*" By Herr Hallmann, architect, from Hanover.

Before examining the existing Russian churches, the author thought it necessary to take a hasty glance at the origin and history of Christianity in Russia, or what amounts to the same thing, at the histoty of those churches. One of the first Christians in Russia was the Princess Olga, who caused herself to be baptized at Constantinople in the year 964; but the era of Christianity in Russia did not commence before the reign of Vladimir the Great. The first church which he caused to be built was that of Cherson, and, a year afterwards, he ordered the construction of the Church of St. Basil, which was, as well as the other, of wood. He sent an embassy into Italy, Arabia, and to Constantinople, to examine the various religions, for the Western and Eastern churches were already separated from each other; and Prince Vladimir, embracing the Greek religion, ordered the baptism of the whole of his people, and was the first to commence destroying the ancient idols. Vladimir built the church of the tithe at Kief; and it is said that, at the time of his death, there were already 500 churches at Kief. Prince Yaroslaf turned his attention still more than Vladimir to the construction of religious edifices; he founded the churches of St. Sophia, at Kief, and another, of the same name, at Novogorod:—they exist, in part, to this day. He also erected the convents of St. George and St. Irene. In 1075 was built the celebrated convent of Petchersky, at Kief, since which time the Russian metropolitans remained subordinate to the metropolitans of Constantinople. Christianity made rapid progress; there remained an uninterrupted communication between Constantinople and Kief, and various marriages between the two reigning houses of the two countries were celebrated. About the year 1124, a great fire destroyed 600 churches and monasteries. In the civil war under Yisaslaf, Kief was taken; it was set on fire: and finally, nearly at the same time that Constantinople was taken by the Venetians, the city of Kief was ravaged and destroyed a second time, never again to realize its former splendour. Moscow is first mentioned in the year 1154, and at that time it was but a miserable village. Daniel of Moscow added to it greatly; and, in the year 1304, under John Danielowitsh, the city was chosen capital of the empire, where, on the 4th of August, 1326, was laid the first stone of the church of the Assumption of the Virgin, in the Krimlin. Under Dimitri Donskoi, the palace of the Krimlin, until then of wood, was erected in stone; and under the reign of Basil the Blind (1425-1462), the church of Russia ceased to be dependant on that of Constantinople, after the taking of that city by Mahomet II. In the year 1487, a palace, known by the name of the Granite Palace in the Krimlin, was built, and in 1499 the Belvedere Palace. Ivan IV. did much for the arts (1534-1584). He likewise renewed the laws for exactly imitating the ancient painting in new churches, whence the reason why all the paintings are so much alike that it is impossible to judge of the epoch, but they may be regarded as a sure type of the earliest Christianity. About the year 1600 the Tzar Boris caused the erection of the magnificent clock-tower, Ivan Valiki, at the Krimlin; and at this period Moscow reckoned 400 churches, of which 35 were at the Krimlin alone. From the time of Peter the Great, and particularly at Petersburg, a change of style took place, and the type of the ancient church was replaced by the absurdities of the *rococo*.

After this general view of the progress of Christian art in Russia, the author turned to the consideration of the Russian church itself, and for this purpose he chose for his examination the cathedral church of the Assumption of the Virgin, at Moscow, as holding the middle rank amongst the existing churches, both as to form and time of construction. (1326.) The plan of the church forms an oblong square divided, and the vaults of which are supported by six equal columns in the interior. Upon a first glance, the form of the Greek cross is not noticed, but it is indicated by the arrangement of the cupolas. The more ancient churches often form an exact square preceded by a porch, but here the porch is united with the interior of the church, and the arches of the cupolas are placed as if the church still retained the primitive form. The six columns divide the church into four parts from east to west, and three from north to south. On the eastern side are seen three apsides, only divided by the width of a pillar. The middle apsis is bigger than the side ones; this arrangement is found in nearly all the Greek churches, and these apsides indicate the situation of three altars, which are met with everywhere except in small chapels. The altars are not visible to the public; they are covered or concealed by the iconostasis, an arrangement peculiar to the Greek church. This iconostasis (or image-bearer) is merely a kind of colossal skreen, occupying the whole width of the church, thus dividing it into two different parts. The iconostasis has three doors, a principal one in the middle, and two smaller ones on each side. Behind the lateral doors there is a more particular distribution, which is, that on each side stands a second little iconostasis, occupying only the width of the little apsis, but the arrangement of which, with three doors and an altar behind, is analogous to the great one. This is what is met with in the ancient churches; in the more modern, an alteration has been made, so that at the farther end of the edifice are seen, upon the same line, three different distinct iconostasis. Between the principal door and the lateral ones, there is, in front of the iconostasis, on each side, a place for the choristers. Above and before the iconostasis always rises the principal cupola, and in the cathedral churches, at the foot of the apsis, opposite the iconostasis which support the cupola, are seen on the left a baldachin for the emperor, and, on the right, another for the metropolitan. As to the situation of the cupolas, there is generally one principal cupola in the midst of four smaller ones which surround it, and the small ones are nearly always at the four angles of the Greek cross. In every church, the iconostasis is the principal part, which ought to be a representation of the celestial empire; it is composed of four or five different tiers, four of which are indispensable. Each tier is composed of an unequal number of pictures of saints, painted on tablets or long square surfaces, the place of which is rigorously fixed. On the first tier are the three doors; the middle door (in two foldings) ought to be ornamented with the Annunciation of the Virgin—the Virgin on one of the foldings, and the Angel on the other—accompanied with the heads or emblems of the four evangelists; on the right of the door is the effigy of Christ, on the left that of the Madonna; on the right, after that of Christ, is placed the picture of the saint or of the festival of the church: then come the little doors already mentioned, but they ought only to be single doors; above the little doors is placed, on the left, the Greek cross, on the right the cross of Moses, symbols of the New and the Old Testament. Such are the indispensable arrangements of the first tier. The ground of the whole iconostasis is gilt. On the second tier, in the middle, is Christ on a throne; and on the right is St. John the Baptist; on the left the Madonna (without the child): after that appear, on each side, two archangels and six apostles. On the third tier, in the middle, is seated the Madonna, holding the infant Jesus on her knees; on each side of her are seen the effigies of the prophets. On the fourth tier is placed God the Father, on a throne, with the infant Jesus; on each side the pictures of the patriarchs of the church. Sometimes there is a fifth tier, upon which are seen representations of the history or of the passion of the Saviour. The other parts of the church are ornamented with paintings on a gold ground. The forms of the exterior are very simple; with respect to the upper part of the edifices the adoption is nearly general of the oriental manner of the eleventh and twelfth centuries—namely, the entire rejection of the horizontal line of a cornice, as the crowning of the building for the substitution of arched, or pointedly arched forms—determining the extrados of the vaults. This cylindrical covering is well known in the east, and is even to be seen in Italy at the present day, in the environs of Naples. These extrados are painted in all colours. The Russian churches derive a peculiar aspect from the cupolas which rise above the roof. On beginning to build churches in the eleventh century, the prevalent manner in the east was naturally imitated—that is to say, such cupolas were not employed as are seen, for example, at St. Sophia at Constantinople, or at Venice, but such as are to be met with in the churches of those times in Greece. The form of the cupolas themselves, which are generally placed on an octagonal drum, are extremely various, some having the form of a half globe, others of a flat onion, a bud, or a long pear, &c.

Mr. Hallmann next drew a parallel between the Russian, the original Greek, and the western churches which bear traces of Greek influence. The first Christian temples under Constantine in the east, and even at Rome, were circular or octagonal, and were surmounted by a single dome: afterwards the same disposition we find in the interior of the churches, with few variations, but the exterior assumes the square form, as in the church of Sergius and Bacchus, and St. Sophia at Constantinople. This latter church already evinces in the interior the form of a Greek cross, and may be regarded as the basis of the Russian churches. At the end of the seventh century began the difference of dogmas between the iconoclasts and iconolaters, which ended in the rupture between the churches of the east and the west. From this time, probably, may be dated the custom of not allowing carved images or statues in Greek churches, except statues of angels; wherefore we see *niellos* upon bronze doors of Greek origin, even in Italy, as at Monte St. Angelo, at Canopa in Apulia, and at Amalfi, &c. Another difference, probably one of the consequences of the schism, was the establishing, at each side of the grand altar, a secondary one; not, as in Roman Catholic churches, at the ends of the transept, or in side chapels, but at the extremity of the church, in the same direction as the grand altar. Their place is always indicated by a niche or apsis. In the Russian churches which commenced in the same century, it has been shown that this disposition became typical, and that it is quite conformable to the division and subdivision of the iconostasis. This disposition is to be met with in nearly all the churches of the eleventh, twelfth, and thirteenth centuries, at Bari, Trani, Malfetta, Otranto, &c., where the Greek worship then prevailed. This situation of the altars is seen even where the churches are Roman Catholic, as at Palermo, in the chapel at Martorana and Monreal, and even at Amalfi and Ravello. Considering that this disposition is found in churches of an earlier date, as St. Parenze in Istria, at St. Fosca, &c., and that perhaps even the form of the ancient basilicas might have given rise to this disposition; it may be very possible that the Greeks preserved this form as an ancient custom of the Church, and that it was the Roman Catholics rather who departed from it. This observation is corroborated, if we observe that the ancient writers tell us that there was, on the left of the altar, a place for the deacons of the church, afterwards called the sacristy, and, on the right, an altar for the consecration of the bread and wine for the communion. In Roman Catholic churches, we always see a sacristy at the side of the church, but, in the Greek Church, the priests always robed themselves behind the iconostasis; and, up to the present day, there is an altar at the side of the present one for the preparation of wine and bread. Another very remarkable difference in the Russian churches is the not having separate places for the women, and there is not a single remnant of a tribune or gyneceum—a circumstance the more astonishing as this disposition is met with not only in the East, but also in nearly all the churches on the coasts of the Adriatic Sea, at Bari, &c. The author concluding by passing in review the modern churches erected after Peter the Great, especially at Petersburgh, and by exhibiting and explaining an original design for a Græco-Russian church exquisitely drawn, and embellished with all the attractions of that gorgeous colouring, which is so peculiar a feature in those edifices.

REMARKS ON ARABESQUE DECORATIONS, AND PARTICULARLY THOSE OF THE VATICAN.

Read at the Institute of British Architects, Feb. 3, 1840,

By A. Poynter, Esq., one of the Secretaries of the Institute.

It is an observation which has been very frequently repeated and very variously expressed, that the proper use to be made of the study of the ancients in their works of art, is not to copy, but to endeavour to think like them. Among the principles which guided them, none is more important, or has exercised a greater influence in bringing ancient art to perfection, than that which has been so well condensed into one line by Pope, that

"True Art, is Nature to advantage dressed;"

and if we wish to rival the ancients in the productions of what is at once excellent and original, we must like them seek for original types in the works of nature.

That such a course of study would be analogous to the practice by which the ancients themselves attained so high a reach of perfection, we have sufficient proof. Nothing in art can be imagined more conventional than the orders of architecture, and yet Vitruvius endeavours to derive them all from simple principles. Vitruvius sufficiently indicates it to have been a received principle that the most conventional forms—and a more conventional form than the Corinthian capital it would be difficult to point out, were supposed to have been originally suggested by the forms and accidents of nature.

To follow up the subject of these remarks, would open a boundless field of inquiry. I offer them in the present instance merely as prefatory to a few observations on the arabesque style of decoration, illustrated by a short review of the arabesques in the Loggia of the Vatican, of which the engravings are before you. I propose to inquire how far the artists who designed and executed these arabesques have been indebted to the antique, and how far they have modified the hints derived from that source, so as to adopt their compositions to the purposes they are destined to fulfil.

In speaking of these sorts of compositions as arabesques, I of course adopt the term as it is commonly understood, and need not explain that we disregard both the etymology and the meaning of the term in applying it to the paintings and stuccoes of antiquity, which represent not only foliage and fruits, but also beasts of every species, and imaginary creatures combined and interlaced together. These decorations have also acquired the name of grotesque, from the grottoes or underground buildings in which they have been found—a term we have perverted still more from the sense in which the Italians invented it.

It is remarkable, that the only mention Vitruvius makes of this style of decoration is in reprobation of it—but he describes it so accurately, that the passage is worth repeating, if for no other reason. After pointing out and classifying what he considers legitimate objects for painting walls, such as architectural compositions, landscapes, gardens and sea pieces—the figures of the gods, and subjects drawn from mythology, and the poems of Homer. He proceeds thus, "I know not by what caprice it is, that the rules of the ancients—(observe, that Vitruvius looks up to the ancients in his day, that is to say, to the Greeks)—who took truth for the model of their paintings, are no longer followed. Nothing is now painted upon walls but monsters, instead of true and natural objects. Instead of columns we have slender reeds, which support a complication of flimsy stems and leaves twisted into volutes. Temples are supported on candelabra, whence rises, as from a root, foliage on which figures are seated. In another place we have demi-figures issuing from flowers, some with human faces, others with the heads of beasts, all things which are not, never have been, nor ever can be. For my own part, I hold that painting is to be esteemed only so far as it represents the truth. It is not sufficient that objects be well painted—it is also necessary that the design be consonant to reason and in no respect offensive to good sense." Pliny also laments that in his time, gaudy colouring and quaint forms were held in greater estimation than the real beauties of art. But with all deference be it spoken, there is another side to the question, which these great authorities seem to have overlooked. Conventional decorations of this kind were within the reach of thousands to whom paintings in the higher branches of art were inaccessible, and a more general diffusion of taste must have been at once the cause and effect of their universal adoption—how universal, the remains of Pompeii reveal to us. If we examine the ancient arabesques independently of these prejudices, we shall find endless beauty, variety and originality; graceful details combined in consistent and ingenious motives and analogies, and great skill and freedom in the mode of execution. We shall also find reason to doubt whether the introduction of the arabesque style really had the effect of discouraging painting of a higher class, since even at Pompeii, poetical compositions of great merit are frequently combined with the lighter ground work of the general decoration.

However fanciful and capricious the arabesque style may at first sight appear to be, there can be no doubt that it may be treated according to the general fixed principles of art, and that the artist will be more or less successful as he keeps these principles in view. A due balance of the composition is essential, so that the heavier parts may sustain the lighter through every gradation, and there must be such a disposition as not to cover too much or too little of the ground. Unity of design is to be studied in a connexion of the parts with each other, and in the harmony of the details and accessories, which ought as much as possible to tend so some general aim. It would lead us much too far to enter upon the subject of colour—but it may just be observed, that in the ancient decorative painting, the balance of colour is strictly attended to. Their walls usually exhibit a gradation of dark pannels in the lower part—a breadth of the most brilliant colours in the middle and principal division, and a light ground thinly spread with decoration in the upper part and in the ceiling—an arrangement dictated by the natural effects of light and shade, and reflection. As lightness and grace are the peculiar attributes of arabesque, the foliage which forms its most fertile resource should never be overloaded; its details and modes of ramification ought to be drawn from nature. The poems of Schiller and other German authors have lately been published with a profusion of arabesque decoration in the margin, which are well worthy of attention, both for the ingenuity with which they are rendered illustrative of the text, and for the accuracy, the *botanical* accuracy, with which some of the foliage and flowers are represented, and which form one of the greatest charms of these clever and original compositions.

Although the paintings in the Loggia of Vatican pass under the name of Raffaelle, it is not pretended that they are the work of his hand, nor were his designs. He was indeed the originator and director of the whole, and the character and influence of his taste is visibly stamped on every part. But his coadjutors in the work were artists whose names are inferior to none in the Roman school but his own, such as Guolano Romanino, Perino del Vaga, Benvenuto Tisi, and others, who were occupied not only in the execution but the invention of the details. Francesco Penni, and Andrea da Salerno are particularly noticed as being employed for the figures. Giovanni da Udino for the fruits and flowers, and Polidoro Caravaggio for the releivos. It may be worth digressing to mention, that M. Quatremere de Quincy is of opinion that the sculptures of the Parthenon were produced by similar means, Phidias there performing exactly the same part as Raffaelle in the Vatican—and it is indisputable that the combination of unity of design, with variety of detail which characterizes gothic architecture, could have been produced only by the same system, and by employing the minds as well as the hands, of those by whom the decorations were executed. When we see perfection attained in three distinct styles of art, in three distinct ages, by means precisely similar, it is not too much to assume that these means are probably the right ones.

The Loggi of a Raffaelle, as you will see by the large section which forms one of the permanent ornaments of this room, is an arcade in thirteen compartments. The arches are open, or at least were so originally, toward the court of which the Loggia forms one side. The opposite side, that namely which is represented in the drawing before you, is a wall pierced with windows, one in each arch, giving light to the suite of rooms which contain the great frescoes of the prince of painters. The ceiling of each compartment forms a square cove, on the sides of which are the pannels containing the series of scriptural paintings, the engravings from which are known as Raffaelle's bible. These are his own designs, and some are known to have been touched with his own hand. Both the lateral and cross arches are supported by pilasters about 16 feet high, panelled, and decorated with coloured arabesques on a white ground. It is to these pilasters the present remarks will be confined. Each pilaster on the wall side is flanked by a half pilaster, in which the arabesque is carried through on a smaller scale of composition.

The description of these pilasters will be taken in the order in which Volpato has engraved them, that is to say, beginning on the side next the wall.

1. Notwithstanding the great variety in the composition and details of these works, we shall find a general unity of design pervading throughout, with the exception of the last five of the series, which will be particularly noticed in their turn. Whatever form the composition may take, it is rendered subservient to the introduction of four medallions, or tablets relieved from the back ground in stucco, of contrasted shapes—one like an antique shield—the next circular—the third rectangular—and the fourth spindle-shaped. These medallions occupy the upper part of the pilaster to the extent of about one-third of the whole panel, while the lower part, to the height of the dado, or somewhat higher, is generally filled in such a manner as to afford a *weight of colour*, sufficient to support itself by the side of that member of the architecture, and the marbles introduced into its panels, following in this respect the practice of the ancients. These medallions might appear to violate the due balance of the arabesques if they were identified with them—but the composition is rescued from that fault, by the separate character given to the decoration of the medallions, and by their being detached, and hung as it were, independently upon the back ground. In the general arrangement of the whole, these medallions perform a most important part, connecting the pilasters with the panelled stuccoes adjoining, by their relief, and by means of an accordant style of decoration and a similarity in the subjects represented upon them, neither of which could have been well embodied in the arabesque itself.

It must be admitted that these compositions considered separately are somewhat unequal, and the examples to be first passed in review are by no means the best, but instruction may be derived from a consideration of their defects. The clusters of natural fruit and foliage which surround the windows are continued throughout the series of arches, and are greatly varied in detail, though precisely similar in composition. There is nothing conventional in these festoons—the clusters are simply connected together by a string, and are composed of the most familiar objects rendered with perfect truth. The melon, the orange, the chesnut, the tomata, the olive, grapes of different kinds, pomegranates, gourds of every description, pine and cypress cones are those which most frequently recur, with their foliage and blossoms. The artist has not even disdained the cabbage, cucumber, and the onion. This example may teach us that objects for decoration may be sought throughout the whole range of nature's works with hopes of success.

Unity is again lost sight of in the design No. 18, but the different objects which compose it, are harmonized upon a totally different principle from any which have been hitherto examined, and the effect is rather dependant upon colour than on form. The panels contrast brilliantly with the white back ground, and are relieved and rescued from heaviness by the sharp dark lines which surround them; this is quite antique.

Having now completed the review of this series of arabesques, it is not my intention to detain you by any lengthened observations upon them, such as occurred, having been expressed on the immediate occasions on which they arose. In the resources which the decorative artist can call to his aid, the moderns have greatly the advantage over the ancients, since we possess their materials and our own also. For as long as ancient authors are read, and ancient art appreciated, so long will allusions to the manners, customs, poetry and religion of antiquity be familiar to us, and the symbols to which they gave rise be universally understood; indeed numberless allusions of this kind are constantly before us, and are so familiar, that we forget to inquire their origin. In personification, and the embodying of abstract ideas, the field is as open to us as to them, and we see to what advantage it may be turned by the examples we have just passed in review, and if we add to all these objects, those derived from the useful arts and sciences which may be turned to account in the hands of the skilful decorator, his resources may be considered boundless. For as we have seen in these examples, it is not the familiar aspect of any object which should banish its representation from works of fancy. Every thing depends upon its proper application. The ancients made the best use of whatever they considered most appropriate, and we must endeavour to do the same. Thus on the pedestal of the column in the Place Vendome, which is a professed imitation of that of Trajan, modern arms and habiliments occupy the place of those of the Roman period, sculptured on the original. Whether this translation be as well executed as it might be, is not now the question—I merely notice it as being right in principle. One fertile source we have totally unknown to the ancients, from which materials may be drawn for decoration. Carrying with them the invaluable quality of being in all cases significant as well as ornamental—I mean the science of heraldry—I cannot help thinking that the Greeks who used so much diversity of colour in their architecture, would have availed themselves liberally of the tints of heraldry in their decorations had they been accustomed with it. From the personal allusions it conveys it might be made a much more important feature than it even now is in the decoration of private as well as public buildings, and we have only to study the works of the middle ages for invaluable hints for the work in which it may be applied. The mere display of shields of arms is but one. We shall find heraldry intimately woven into the ornaments of our gothic buildings, and he who can read its language may often understand an allusion in what may appear at first sight a mere decoration. Thus one of the mouldings of the tomb of Humfrey Duke of Glocester, at St. Albans, is filled with an ornament, which on examination resolves itself into a cup containing flowers, a device assumed by that prince, says a MS. in the College of Arms, as a mark of his love for learning. Heraldry has not been neglected in modern Italian art, and I remember in particular a very well imagined arabesque in the Town-hall at Folisno. The ceiling is covered with foliage, spreading from the centre.

In the pilaster No. 3, many of the details are in the true spirit of the antique—the single figures are less so. An ancient painter would not have placed them on a scrap of earth. In the Pompeian decorations, the detached figures—I do not speak of such as are inclosed in frames—but the *detached* figures, partake of the artificial character of the style to which they are adapted, and if they are not represented as floating in the air, they stand upon a bracket, or a mere line, or on any thing but the natural ground.

My objection to some of the terminal figures is, that they are improbable. Improbable I mean upon certain postulates, which it is necessary to assume before we can reason upon these imaginary compositions at all. The mythology of the ancients has peopled the elements with beings compounded of the human and brute creation; their intelligence being indicated by the first, and their fitness for the region they are supposed to inhabit by the second. There is nothing in ancient art in which greater taste or judgement is displayed than in some of these combinations. The animal functions appear in nowise compromised by the mere interchange of corporal members, between different species. Such combinations therefore, as long as they involve no glaring disproportions, present nothing repugnant to the mind, and we are so familiarized to them, that we pronounce upon the success of the representation of a triton, a satyr, or a centaur, with as little hesitation as we might upon that of any of the animals of which they are compounded. We are equally ready, or perhaps owing to a stronger association of ideas, *more* ready to admit of aerial beings, supporting themselves on wings, floating in the ether, or alighting upon a flower without bending the stalk; though these are, in fact, less probable than those born of the ocean or the earth. Between animal and vegetable life there is also a sufficient analogy to attach some probability, or at least to afford an apology, for the graceful combinations between these two kingdoms of nature, invented by the ancients, and adopted to a very great extent in the compositions before us; but, when we come to combine animal life with unorganized matter, the probability ceases, and if, as in the case before us, the unorganized portion is something artificial, and totally out of proportion, besides the combination becomes intolerable. Thus we acquiesce in the metamorphoses of Ovid or the Arabian Nights, as long as certain analogies are observed—but the transformation of the ships of Eneas into sea nymphs, is a violation of probability to which nothing can reconcile us.

No conventional form has been more abused than the terminus; intelligence and immobility are the attributes which the ancients intended it to embody, but their apposite creation is totally different from anomalous composition like this into which it has been tortured.

In No. 5 we arrive at a superior composition, for it must be repealed; we are examining the decoration of a single member of an extensive *whole*, and that, however beautiful each may be, unity is a beauty in addition. No object in decoration has been so extensively used as the scroll. The ancients do not appear to have been afflicted with an unhappy craving for novelties, nor to have been haunted with the apprehension that beautiful forms of composition would become less beautiful by repetition. When the most appropriate forms in architecture and decoration were once ascertained, they were continually repeated, but marked with a fresh character, and stamped with originality by those refined and delicate touches which were all-sufficient when they were properly appreciated. In the same manner with regard to the ever-recurring form of the scroll, as long as the foliage and ramifications of nature are unexhausted, so long will it be capable of assuming an original character in the hands of the skilful artist. A striking illustration of this position may be drawn from the arabesques in the palace of Capsasola, where the pilaster of the Loggia are decorated with scrolls, all similar in composition, but each formed of a different species of natural foliage without the intermixture of any thing conventional except the regularity of the convolutions.

For the magnificent scroll before us we are indebted to the antique; it is an imitation of the well known frieze of the Villa Medici, but the artist has made it his own by the skill with which he has adapted it to his purpose, both in proportion and colour. Nothing can be more happy than the manner in which the upper part grows from the original design. I would particularly call your attention to the animals—the squirrels, the mice, the lizards, the snake, the grasshopper, and the snail, dispersed about the branches, so well calculated to fill the spaces they occupy, and at the same time producing a variety which would have been wanting, had the foliage only been extended with that object. To the scroll in the half pilaster it is to be objected that it is a repetition in small, of that in the principal compartment—but if examined separately, it will be found full of instruction from the union it displays of natural objects with conventional forms. The spiral line of the antique scroll is evidently drawn from the natural course of climbing plants,—it is conventional in its openness and regularity. The involucra of plants furnish the hint for the base from which the antique scroll is made to spring and the spathes of the liliaceous tribe for the sheaths, of a conventional repetition of which, the ancient sculptured scrolls principally consist. Thus far for the general elements of the antique scroll, which the artist has implicitly followed in the example before us; but he has enriched his composition without disturbing its unity, by making every sheath produce a different branch, drawn immediately from nature. The birds present an equal variety, and are occupied according to their natural habits, in feeding on the berries and buds, or on the variety of insects which are also introduced. The arabesques in the side panels are to be particularly noticed in this example. A *motion*, however slight, is always to be desired, and here we see a very graceful one in the two winged boys who dip into a vase-like fountain. The winged bear which occupies the medallion may be noticed as a violation of probability. A being to cleave the air should not be selected from the most heavy and awkward of animals; it is undoubtedly intended for a *jeu d'esprit* and is quite in the spirit of the antique. The ancient frescoes are full of such whimsical combinations, but always as in the present instance, occupying a subordinate place.

No. 7. is one of the most remarkable of the series. In this the artist has ventured, and with the most perfect success, to discard every thing conventional, and to represent a natural tree, balancing its irregularities of ramification and foliage by the numerous birds which occupy the branches, when they may be supposed to have been collected by the call of the bird-catcher, who is concealed in the underwood with his bird-call in his mouth. One bird, fettered by a limed twig, is about to fall into his hands. It is impossible to admire too much the skill with which this simple *motion* is worked out.

It may be observed in reference to Nos. 4 and 11. that folds of drapery are too broad and heavy to be successful in arabesque—its effect is seldom pleasing. I must also protest against the birds which crown this composition. Nature has provided a variety which makes it quite unnecessary to seek novelty by combining the neck of one species and the tail of another with imaginary wings. The first impression is, that these birds are meant for swans; the second, and abiding one, that the artist did not know how to draw a swan; he has not mended them by dressing them in trowsers.

In No. 15. the artist has chosen the apparently incongruous subject of fish to combine with his foliage. In a painting by Hogarth, we see in the fashionable furniture of one of his scenes, a composition of foliage inhabited by fish instead of birds, although this absurdity be intended as a caricature of the talk of the day, it is no great exaggeration of the fact. In this design, the foliage and the fish are brought together without the slightest violation of probability; the fish have been hung to the branches—the variety of their forms and colours produces an admirable effect, and above all, they are perfect in the condition, more especially indispensable in objects not intrinsically graceful or pleasing, of being represented with the most absolute truth to nature.

INSTITUTION OF CIVIL ENGINEERS.

SESSION 1840.—ANNUAL REPORT.

The Council of the Institution of Civil Engineers, on resigning the trust confided to them by the last annual general meeting, solicit the attention of this meeting, and of all those who are interested in the welfare of the Institution, to the following report on the proceedings and on the state and prospects of the Institution at the close of this the twenty-first year of its existence. At the last annual general meeting, the council of the preceding year had the gratification of congratulating the Institution on its then assembling in its new premises under circumstances which furnished so advantageous a contrast with the condition of earlier years, and such convincing evidence of the steady progress and success which had attended the labours of the Council and the co-operation of the general body. And though the year which is now closing upon you may not have been marked by events of so striking a character as the preceding one, the council nevertheless experience the highest degree of satisfaction in reviewing the proceedings of the session of the year so auspiciously commenced. Aware of the more extensive duties and increased responsibility entailed upon them, the council have endeavoured so to direct the affairs of the Institution as to keep pace with its growing importance; and they can with confidence assert, that the proceedings of the last session have not been inferior in interest or importance to those of any preceding session; whilst the attendance at the meetings, and the anxiety which is evinced by strangers to become acquainted with the proceedings and objects of the Institution, show the estimation in which it is held both at home and abroad, and fully warrant the most sanguine anticipations of its future and continually increasing success.

The attention of the last annual meeting was directed to the expediency of some alteration in the existing laws, particularly with reference to the election of officers and the number of the council. It was suggested that the annual election of the council should be conducted in a somewhat different manner from that hitherto pursued; that a greater number than that constituting the council should be nominated, and that, consequently, each person at the annual general meeting, instead of, according to the then existing practice, erasing one name and substituting another, should erase as many names as the number on the balloting list exceeded the constituted number of the Council. It was also suggested, that it would be for the advantage of the Institution that the council should be increased by the addition of two members: that as some members of the council are frequently prevented by professional engagements from regular attendance, the council should be enlarged to as great an extent as might be consistent with the true interests of the Institution. These and some other suggestions for the better regulation and stability of the Institution, were subsequently submitted to a general meeting of the members, and now constitute part of the bye-laws of the Institution.

The practice of other societies in publishing their transactions in parts, containing such communications as were ready at frequent and short intervals, was briefly touched upon in the last report, and was discussed in considerable detail at the last annual meeting. Such is the nature of some communications, that delay in their publication may be considered not only as a positive injustice to the author, but as detrimental to the cause of practical science, and the best interests of the Institution; and if the publication of such papers be delayed until a whole volume is ready, authors will inevitably avail themselves of other channels for bringing their labours before the world. Add to which, when a whole volume containing many valuable plates is to be published, the sources of delay are numerous, and such as cannot be avoided. The council conceive that the experience of the past year has fully borne out the preceding views, and shown the great importance and value of prompt publication. Early in the session the Institution received a most valuable communication from your member, Mr. Parkes. It was considered desirable that the publication of this communication, forming, as it did, a continuation of his researches already published in the second volume of the transactions, should not be delayed. No other communications being then ready for publication, the council resolved to publish it at once as the first part of the third volume. This has now been for some time in the hands of the public, and the number of copies which have been disposed of shows the great desire evinced to obtain these papers as soon as published. The council have also had still further proof of the importance of this plan. The Institution received, during the last session, several communications well suited for publication in the Transactions, and among them, the continuation and conclusion of that already mentioned by Mr. Parkes. Preparations were made for the immediate publication of these papers in a second part; difficulties and delays which could not have been foreseen or prevented, occurred in the publication of some of them, and thus the second part contains but two instead of the nine communications originally destined for it. The greater portion of the remaining seven papers are already printed and the plates engraved, so that the third part will be in the hands of the Institution in a very short time. There are several other valuable communications in the possession of the Institution now in the course of preparation for publication, and which will appear as soon as circumstances will permit.

The minutes of proceedings have been printed at such short intervals during the session, as the abstracts of papers and minutes of conversation would furnish sufficient materials. The council conceive that great advantages may, and indeed have, resulted from a publication of this nature. An authentic account of the communications is thus immediately furnished, attention is continually kept alive to the subjects which are brought before the Institution, and the statements there recorded have elicited very valuable communications, which otherwise would probably never have been brought forth. No one can turn over the minutes of the last session without remarking the number and the diversity of the facts and opinions there recorded, very many of which were elicited by the statements contained in some written communication, or casually advanced in the course of discussion.

The council cannot omit this opportunity of insisting on the importance of these discussions in promoting the objects which the Instituion has in view. The recording and subsequent publication of these discussions are features peculiar to this Institution, and from which the greatest benefits have resulted and may be expected, so long as the communication of knowledge is solely and steadily kept in view. It would be easy to select many instances during the last and preceding sessions, of some of the most valuable communications to the Institution owing their origin entirely to this source. The first communication from Mr. Parkes arose entirely out of the conversations which took place on the superior evaporation of the Cornish boilers being referred to as one cause of the great amount of the duty done by the Cornish engines. The communication by Mr. Williams on peat and resin fuel owes its origin to his being accidentally present at the discussion on the uses of turf in the manufacture of iron; whilst that by Mr. Apsley Pellatt, on the relative heating powers of coke and coal in melting glass, arose entirely from the discussion of the facts stated by Mr. Parkes respecting the superior evaporation produced by the coke from a given quantity of coal than by the coal itself. And lastly, the extremely interesting and highly valuable discussions at the commencement of last session on the uses and applications of turf; and on the extraordinary coincidence between the results obtained by Mr. Lowe, Mr. Parkes, Mr. Apsley Pellatt, and Marcus Bull, of Philadelphia, experimenting as they did with totally different views, and under totally different circumstances, must be fresh in the recollection of all present.

But, besides the positive advantages which have thus resulted, and may be expected, from a steady adherence to these practices so peculiar to this Institution, there are others of the greatest value to those engaged in practical science. By this freedom of discussion statements and opinions are canvassed, and corrected or confirmed, as soon as promulgated, the labours of authors and claims of individuals are made known and secured as matter of history—and attention is continually kept alive to the state and progress of knowledge in those departments of science which it is the especial object of this Institution to promote. The council trust, therefore, that those individuals who have stored up knowledge and facts for many years past, and devoted themselves to some particular branch of science, will consider how much they have in their power to contribute, and how great is the assistance which they can render to the labourers in other branches, and, above all, to those who are ambitious of following in their steps, by freely communicating, either orally or in writing, the knowledge which they have collected; so that the records of the Institution may be unparalleled for the extent and correctness of the information which they contain.

The council have endeavoured from time to time to direct attention to subjects on which it was conceived communications were needed or desirable, by proposing such subjects as objects for the premiums, placed at the disposal of the council by the munificence of the late president. The communications sent in compliance with this invitation have not been numerous. Two, however,—one by your associate Mr. Jones, on the Westminster Sewage, and the other by Mr. Hood, on Warming and Ventilating,—seemed to call for some special mark of distinction.

The communication by Mr. Jones is of the most elaborate and costly description. (*See Journal*, vol. 2, p. 311). The council conceived that, in awarding to Mr. Jones a Telford medal in silver and 20 guineas for this laborious communication, they were bestowing a suitable mark of approbation on the author of a record which is nearly unparalleled, and must be of great value as a source of information in all future works of this nature, when other, and particularly foreign, cities carry into effect a system of drainage, in which they are at present so deficient.

The council cannot pass from this subject without expressing the obligations which the Institution is under to the chairman and the commissioners of the sewers of the Westminster district. On its being intimated to them that the council wished some account and record of the work over which they preside, permission was immediately given for any person desirous of preparing such account to have free access to all the documents in their possession relating to this subject, and to make such extracts or copies therefrom as could in any way contribute towards this object.

The communication by Mr. Hood contains a detailed account of the principles on which the salubrity of the atmosphere in crowded rooms depends, and the various methods which have been adopted for warming and ventilation. (*See Journal*, vol. 2, p. 469). The importance of ventilation, and the success which has attended the adoption of mechanical means in the manufacturing districts, are subjects worthy the attention of all who study the health of those who, from choice or necessity, are exposed to the generally unwholesome atmosphere of crowded apartments. This subject is of the highest importance to the manufacturing poor of this country, who are compelled to work in crowded rooms at high temperatures. The council are aware that much has been done towards this object in some of the large cotton works of Great Britain, and they hope ere long to obtain some detailed account of the means by which this has been accomplished, and the results which have ensued.

The council have also awarded a Telford medal in silver to your associate, Charles Wye Williams, for his communication on the Properties, Uses, and Manufacture of Turf Coke and Peat Resin Fuel; and to Mr. Edward Woods, for his communication on Locomotive Engines.

The various applications of peat as a fuel had been repeatedly the subject of discussion at the meetings of the Institution, and this communication may (as has been already noticed) be attributed to the discussions then going on. (*See Journal*, vol. 2, p. 145).

The communication by Mr. Edward Woods, published in the second volume of the Transactions, will always bear a prominent place among the records of practical science, as one of the earliest and most accurate details on the actual working of locomotive engines. The first communication was received early in the session of 1838. (*See Journal*, Vol. 1, p. 139.) The author was thought capable of adding so much to his already valuable communication, that the council referred it back to him for this purpose, and it was not received in the form in which it appears in your Transactions till after the premiums for that session were awarded. But this communication (notwithstanding the interval since it was laid before the meeting) will probably be fresh in the recollection of most present, from its giving an accurate account of the progress of the locomotive engines on the Liverpool and Manchester Railway from the opening of that important work. The experience of engineers had at that time furnished them with but little knowledge as to what were the most essential requisites in railway engines, and the advance of knowledge, as shown by the history of the locomotive engine on this railway, is a most interesting and instructive lesson to every one who would study the progress of practical science and improvement. Great alterations were found necessary in the strength of the parts, in the weight of the engines, in the road, and the number of wheels. The first engines were gradually adapted to the necessities of the case, and the arrangements then resorted to as necessary expedients have now been adopted into the regular and uniform practice. Besides the extreme interest of that which may be termed the history of these improvements, the communication is replete with theoretical principles as to the working of locomotives, and the advantages and disadvantages incident to peculiar practical adaptations. It would exceed the limits of this report to do more on the present occasion than briefly to state that this paper contains extended remarks on the relative advantages of four or six wheels, of inside or outside framings, of crank axles or outside crank pins, of coupled or uncoupled engines. The council would point out this paper to the junior members of the profession, as an example of how great a service may be rendered by simply recording what passes under their daily observation and experience.

The council have also adjudged a Telford medal in bronze and books to the value of three guineas to Mr. R. W. Mylne, for his communication on the Well sunk at the reservoir of the New River Company at the Hampstead-road, (*see Journal*, vol. 2, p. 311); to Lieutenant Pollock, for his drawings and description of the Coffer Dam at Westminster Bridge, (*see Journal*, vol. 2, p. 311); and to Mr. Redman, for his drawings and account of Bow Bridge.

Among the other communications of the session, the council cannot, on the present occasion, omit to notice those of your member, Mr. Parkes. His communication on the Evaporation of Water from Steam Boilers, (*see Journal*, vol. 1, p. 170), for which a Telford medal in silver was awarded during the preceding session, and the interesting discussions to which it gave rise, are too well known require further comment. But great as were the benefits conferred on practical science by the facts there recorded, they have been much surpassed by the subsequent labours of this author. In continuation of his subject, you received early in the session the first part of a communication on Steam Boilers, (*see Journal*, vol. 2, p. 225); and at the close of the session, the second part, treating of Steam Engines. Before Mr. Parkes was induced to turn his attention to the preparation of these communications, no attempt had been made to bring together, in one connected view, the various facts which had been ascertained. The economy of the Cornish system was indisputable; but to what it was to be referred was involved in some obscurity. It was reserved for this communication to call attention to certain quantities and relations which exerted a peculiar influence over the results; and which, being rightly ascertained, were at once indicative or exponential of the character of the boiler. If it be found that, in one class of boiler, the same quantity of coal is burnt eight times as rapidly as in another class—that the quantity consumed on each square foot of one grate is twenty-seven times that on the grate of another—that the quantity of water evaporated bears some definite relation to the quantity of heated surface—and that there is twelve times more evaporated by each foot of heated surface in one class of boiler than in another—and finally, that the quantity of water evaporated by a given weight of fuel is in one class double the quantity evaporated in another,—we have arrived at some definite relations whereby to compare boilers of different kinds with each other. To these definite quantities and relations, the author, with apparent propriety, assigns the term "exponents;" and these being compared together for different boilers, their respective merits as evaporative vessels are readily perceived. Mr. Parkes has also called the attention of engineers to the effect of the element time, that is, the period of the detention of the heat about the boiler. The importance of attending to this cannot be too strongly insisted on; as it would appear from these statements, that boilers being compared with each other, in respect of their evaporative economy, are nearly inversely as the rate of combustion. Attention is also called to the fact, that there are actions tending to the destruction of the boiler entirely independent of the temperature of the fire, and which may be designated by the term "intensity of calorific action." Of their nature we know nothing, but the durability of different boilers, under different systems of practice, affords some means of comparing the intensity of these actions.

Mr. Parkes having, in the first part of the subject, thus pointed out the distinctive features of the different classes of boilers as evaporative vessels, proceeds, in his subsequent and concluding communication, to consider the distribution and practical application of the steam in different classes of steam engines. And for this purpose, he is led to consider the best practical measure of the dynamic efficiency of steam—the methods employed to determine the power of engines—the measures of effect—the expenditure of power—the proportion of boilers to engines—the standard measure of duty—the constituent heat of steam—the locomotive engine—the blast and resistance occasioned by it—the momentum of the engine and train, as exhibiting the whole mechanical effort exerted by the steam—the relative expenditure of power for a given effect by fixed and locomotive non-condensing engines. This bare enumeration of the principal matters in the second communication will give some, though a very inadequate, idea of the magnitude of the task undertaken by Mr. Parkes, for the communication is accompanied by elaborate and extensive tables, exhibiting the results of the facts which he has collected and used in the course of his inquiry, and it may confidently be asserted that a more laborious task has rarely been undertaken or accomplished by any one individual than the series of communications thus brought before the Institution.

It will be one of the earliest duties of the succeeding council to consider in what manner the sense of the great benefits conferred on this department of practical science can most appropriately be testified.

The council also received, at the close of last session, from your member, Mr. Leslie, a most valuable communication on the Docks and Harbour of Dundee. This is one of the records on which the Institution sets the highest value, being the detailed account of an executed work of great extent. It is not, in its present form, well adapted for being laid before the meetings; but on its publication, which will take place very shortly, the Institution will have an opportunity of judging of the high value which it possesses.

In acknowledging, with gratitude, the numerous and valuable presents made to the Institution during the past year, the council would call the attention of the members generally to the want still existing in the library of works of reference on general scientific subjects not immediately connected with engineering, and express a hope that such wants may be supplied by that liberality to which the Institution is already so deeply indebted. The collection of models also requires many additions to render it as complete as the council could wish, and it is only by the wants of the Institution being constantly borne in mind by all who are i nterested in the subject, that such a collection can be formed as shall be worthy of the Society.

Several societies have made an exchange of Transactions with the Institution, and from the Royal Society of Edinburgh, the Philosophical Society of

Manchester, the Royal Irish Society, and the Royal Astronomical Society, sets of Transactions, as complete as could be made up, have been received The Master-General of the Ordnance, the Lord-Lieutenant of Ireland, and Colonel Colby, continue their liberal presents of the English and Irish Surveys; and Captain Beaufort and the Secretary of the Admiralty have continued the present of the series of Admiralty Charts. The Institution is also indebted to Mr. Vignolles for the Busts of Locke and Dr. Hutton; to Mr. Field, V.P., for a Bust of the late Henry Maudslay; and to Mr. Rivers, for that of Dr. Faraday.

The council would wish to take especial notice of the large collection of works of the late eminent philosopher, Dr. Young, now deposited in your library. For this great acquisition, the Institution is indebted to the kindness and liberality of his brother, Mr. Robert Young, who conceiving most justly that every thing connected with so great a benefactor to practical science must be highly valued by this Institution, has made it the depository of these books from the library of his distinguished relative. The council, in thus publicly recording their sense of the kindness and liberality of Mr. Robert Young, would earnestly press upon others the importance of following so noble an example, and of presenting such works as are at their disposal, and of which the library of the Institution is particularly in need.

It is announced through the medium of the last Annual Report, that the monument of Telford was nearly finished, and that a site had been selected in Westminster Abbey. The council have now the satisfaction of announcing that the monument is fixed in the place destined for it, and they are confident that all who enjoyed the acquaintance, or knew the merits, of the late distinguished president of this Institution, will rejoice that the memory of one so eminent and so highly deserving has met with so proper and just a tribute of respect; whilst all, no less than those by whose liberality the monument was erected, will feel that he has a name which will endure so long as there exists a record of the triumphs of the British engineer.

It would be vain to expect that an annual meeting should ever recur without the council having to lament the removal by death of some who, by their acquirements, or by their associations of friendship, were endeared to the Institution. On the present occasion the council have to lament the death of your members, Mr. David Logan and Mr. Henry Habberley Price, and of your honorary member, Mr. Davies Gilbert. The records of the Institution contain several communications from Mr. Logan, particularly one on the new Graving Dock at Dundee, and Mr. H. H. Price was, when in town, a constant attendant at the meetings, and took a lively interest in the proceedings and success of the Institution. Mr. Davies Gilbert was, by his writings and his influence, a great benefactor of practical science, and the Transactions of the Royal Society, over which he presided for three years, contain several papers of great value to the practical engineer. He took great interest in the introduction of Mr. Watt's improvements in the steam engine into the Cornish mines, and in the controversy betwixt Mr. Watt and Mr. Jonathan Hornblower respecting working steam expansively, the former employing one cylinder only, the latter two cylinders, in the manner afterwards revived by Woolf; the theoretical efficiency of the two methods being identical, but simplicity and mechanical advantage being greatly in favour of the former, as its present universal adoption testifies. Mr. Davies Gilbert introduced into practical mechanics the term "efficiency" as the product of the applied force and of the space through which it acted in contradistinction of the term "duty," as indicative of a similar function of the work performed. His attention was also directed to the theory of suspension bridges, when the plan for making such communication across the Menai was submitted to the commissioners appointed by parliament. It appeared to him that the proposed depth of curvature of the catenary was not sufficient, and his well-known theoretical investigation of this subject was undertaken with the view of ascertaining this fact; and in consequence of these investigations, the interval between the points of support of the chains and the roadway was increased to the height which appeared to him requisite for works of this nature. The labours of this distinguished individual for the promotion of science were unremitting. He was the founder of several societies; he was the discoverer and early patron of the talents of Davy; and while in parliament he laboured most assiduously in the advancement of all the public works. Regret for such a man, exerting the power of his mind so advantageously and through so many years, must always be strong and sincere; but having attained the ordinary limit of human life, he sunk into the grave amidst the respect and esteem of all who knew him, and has left behind him a name which will ever bear a prominent place amidst the names of those whose lives and talents have been devoted to great and noble purposes.

GEOLOGICAL SOCIETY.

On the relative Ages of the Tertiary and Post-Tertiary Deposits of the Basin of the Clyde, by James Smith, Esq., of Jordan Hill.

In former communications Mr. Smith showed that deposits in the basin of the Clyde had been elevated above the level of the sea during very recent geological epochs, and that some of these beds contain testacea which indicate the prevalence, during the period of their accumulation, of a colder climate in Scotland than exists at present. In this paper he confines his remarks to subsequent observations, which afford most satisfactory evidence that these comparatively modern deposits are divisable into two distinct formations, differing in their fauna, and separated by a wide interval of time. In the older of these formations Mr. Smith has found from 10 to 15 per cent. of extinct or unknown species of testacea; but in the newer only such shells as inhabit the British seas. He accordingly places the former among the newest pliocene or pleistocene deposits of Mr. Lyell, and the latter among the post-tertiary series. Both of these accumulations, he, nevertheless, considers to be older than the human period. In the lowest part of the pleistocene formation of the basin of the Clyde, Mr. Smith places the unstratified mass of clay and boulders, locally called "till," and in the upper, which rests upon it, the beds of sand, gravel, and clay, containing marine shells, a portion of which are extinct or unknown. He is of opinion that some of the similar accumulations in the basins of the Forth and the Tay, will probably prove to be of the same age, as well as the elevated terraces of Glenroy, recently shown by Mr. Darwin to be of marine origin. He is also convinced that a very great proportion to the superficial beds of sand, gravel, and clay will be ascertained to be tertiary, although the absence of organic remains must render it difficult to obtain, on all occasions, satisfactory evidence. During the post-tertiary epoch, or while the beds containing only existing testacea were accumulated, changes of level in the basin of the Clyde must have taken place to the amount of forty feet; but during the human period no change appears to have occurred.

The paper concludes with a list of the fossil shells obtained by Mr. Smith, and not found living in the British seas, or of doubtful existence in them. The number of the species is twenty-four—six of which occur in the crag of England, three in the most recent tertiary strata of Sweden, and seven in a living state in the North seas.

On the noxious Gases emitted from the Chalk and overlying Strata in sinking Wells near London, by Dr. Mitchell.

The most abundant deleterious gas in the chalk is the carbonic acid, and it is said to occur in greater quantities in the lower than the upper division of the formation. The distribution of it, however, in that portion of the series is very unequal, it having been found to issue in considerable volumes from one stratum, while from those immediately above and beneath none was emitted. Sulphuretted hydrogen and carburetted hydrogen gases sometimes occur where the chalk is covered with sand, and London clay, as well as in other situations. In making the Thames Tunnel they have been both occasionally given out, and some inconvenience has been experienced by the workmen, but in no instance have the effects been fatal. In the districts where sulphuretted hydrogen gas occurs the discharge increases considerably after long-continued rain, the water forcing it out from the cavities in which it had accumulated. The paper contained several cases of well-diggers having been suffocated from not using proper precautions.

The tables of the Meeting-room and the Library were covered with donations of specimens and books.

Wednesday, November 20.

Four communications were read.

An extract from a letter addressed to Dr. Andrew Smith by Mr. A. G. Bain, dated Graham Town, Cape of Good Hope, Feb. 21st, 1839, announcing the discovery of the skull and piths of the horns of an ox in an alluvial deposit on the banks of the Modder, one of the tributaries of the Orange River, and forty feet below the surface of the ground. The piths measured, in the direction of their curvature, and including the breadth of the os frontis, eleven feet seven inches, but it is calculated that about five inches had been broken off each point. Their circumference at the root was eighteen inches, and the orbits are described as situated immediately under the base of the horn. Other portions of the head, and five molar teeth, were found at the same time.

On the Origin of the Vegetation of our Coal-Fields and Wealdens, by J. T. Barber Beaumont, Esq.

The author of the communication is of opinion, that the plants discovered in the coal measures were not drifted into large estuaries and there sunk, but that they grew where they are found, and that the districts now forming our coal-fields were originally islands. The principal objections advanced in the paper, against the theory of the transportation of the plants by great rivers, are, that such bodies of water would have required for their existence extensive continents, of which there are no traces; that, as the coal strata near Newcastle are 380 yards in thickness, the depth of the estuary must, in that case, have exceeded six times the mean depth of the German Ocean; that the formation surrounding the coal-fields are of marine origin, and bear no traces of having been dry land at the same time the coal and its associated strata were accumulated; and that the freshness of the plants is opposed to the view of their having been drifted from a distance, and sunk in a deep estuary —a process which must have been accompanied by a certain extent of decay in the plants. Mr. Beaumont then briefly proposes the following, as a preferable theory to account for the production of the coal-fields:—He supposes that they were originally swampy islands, on which plants flourished, and in part decayed; that the islands, during the settling of the earth's crust, were submerged, and covered with drifted clay, sand, and shells, which buried the plants; that these accumulations gradually raised the surface of sunken islands till it again became dry land, and adapted for the growth of another series of plants; and that these processes were repeated as often as there are alternations of coal and strata of earthy sediment.

On the Fossil Fishes of the Yorkshire and Lancashire Coal-Fields, by Mr. W. C. Williamson.

Within the last four years the coal measures of these countries have assumed a zoological importance, which previously they were not supposed to possess. In Lancashire icthyolites have been lately found to pervade the whole of the series from the Ardwick limestone to the millstone grit, and in Yorkshire they have also been obtained in great abundance. On comparing the specimens procured at Middleton colliery, near Leeds, with the fossil fishes of Lancashire, the author detected the following as common to both coal-fields, viz.:—*Diplodus gibbosus, Ctenoptychus pectinatus, Megalicthys, Hibbertii, Gyracanthus formosus*; also, remains of apparently species of Holoptychus and Platysomus; but he has obtained some icthyolites in the Yorkshire field which he has not seen in the Lancashire, and he is of opinion that the latter deposits are characterised by the greater prevalence of lepidoid fishes, and the former by sauroid. These remains, except in the case of the Ardwick limestone, always occur in highly bituminous shale, and they are most abundant where it is finely grained, and in general where plants are least numerous. This distinction in the relative abundance of icthyolites and vegetables, Mr. Williamson conceives may throw some additional light upon the circumstances under which the coal formations were accumulated. The fishes are found chiefly in the roof of the coal, rarely in the seam itself, and not often in its floor. Mr. Williamson, in conclusion, makes some remarks on the manner in which icthyolites are associated with the other fossils of the coal measures. At Burdiehouse they occur in the midst of freshwater shells and Cypris; at Coalbrook Dale with marine testacea; in the lower coal measure of Lancashire, not far from the beds containing *Goniatites Listeri*, and *Pecten papyraceus*; higher in the same field, and in Yorkshire, they are associated with freshwater shells; at Middleton with Lingulæ; and at the top of the series in Lancashire and Derbyshire with Mytili and Melaniæ.

A paper on the Geology around the Shores of Waterford Haven, by T. Austin, Esq.

As the object of this communication is to describe topographically the structure of the shores of Waterford Haven, its details do not admit of abridgment. The formation composing the district are mountain limestone, a conglomerate, clay-slate, and trap, the limestone and conglomerate constituting the greater portion of the east side of the Haven, and the conglomerate the opposite.

REVIEWS.

On Steam-Boilers and Steam-Engines. By JOSIAH PARKES. Transactions of the Institution of Civil Engineers, vol 3. London: J. Weale. 1840.

PART II.—ON STEAM-ENGINES, PRINCIPALLY WITH REFERENCE TO THEIR CONSUMPTION OF STEAM AND FUEL.

IN our Number for July last we noticed the part of this investigation, which treated of the qualities of steam-boilers, and of the influence exercised over evaporation by their proportions and practical management. Of that part we considered the only value to consist in the *facts* therein recorded.

In the introduction to this part the author makes the following very sensible observation:

"The generation and application of steam are distinct problems; they require to be separately treated, and their results to be separately stated. It is the economy of steam which constitutes the dynamic perfection of an engine; it is the economy of heat in supplying steam to an engine; which constitutes the evaporative perfection of a boiler; and it is only by distinguishing the effects of e ch, that the value of any change of practice, in either department, can be correctly ascertained."

Now, although there may be few, if any practical e ineers, who would be disposed to doubt the truth of this remark, yet we are persuaded that it is not in general duly appreciated, or at least, that very little attention is paid to it by them.

The author has divided this part into two portions: in the first, which occupies about one-fourth of the whole, he has investigated the atmospheric, the stationary non-condensing, or the high-pressure, the low-pressure condensing, and the Cornish high-pressure expansive pumping engines. The facts established on these four varieties are collected and exhibited in a comprehensive table, (table 6.) The last three-fourths of the work are dedicated solely to the locomotive engine, the chief part tending to prove the inaccuracy of all the estimations which have hitherto been made of the several resistances which have to be overcome by that variety of engine. The author has, however, also developed a *new theory of the locomotive engine*, the fallacy of which will be at once evident to the scientific reader; but its plausibility might induce the practical man (who has not the means of detecting theoretical errors,) to put implicit faith in its correctness. For his sake, therefore, we shall feel it necessary to take more notice of this new theory than we should otherwise have done.

The two sections in which the author treats *of the methods employed to determine the power of engines*, and *of the measures of effect*, present nothing worthy of notice: but in the next section, which treats *of the expenditure of power*, we have to point out an error, which we thought to be already so thoroughly eradicated, that it could never more find its way into any work having the slightest pretensions to science. This section commences thus:

"The ponderable element of steam is water: its consumption by an engine is appreciable; and it is now assumed, almost universally, that the sum of its imponderable element, heat, is a constant quantity, in steam of all specific gravities. The elastic force of steam is also generally assumed to be proportional to its density: thus, equal amounts of heat and water are expended in the generation of equal power, at whatever pressure steam be used by an engine."

We admit the first assumption, that the quantity of heat contained in a given weight of steam is a constant quantity, whatever may be its density; but it is not a fact, as Mr. Parkes assests, that the elastic force of steam is also generally assumed to be proportional to its density: indeed a comparison of the numbers given in the table, (page 122,) which he himself took from M. de Pambour's *New Theory of the Steam Engine*, would have convinced him at once that that assertion was not well founded. For we there find the volume of steam formed from a volume of water equal to unity is equal to 2127, when generated under a pressure of 10lbs. on the square inch; and 677, when generated under a pressure of 40lb. We ought, therefore, to have, since these volume are inversely proportional to the density of the steam,

$$10 : 40 :: 677 : 2127,$$

which would give, by making the product of the means equal to that of the extremes,

$$21270 = 27080,$$

which is absurd. The conclusion drawn from this law is therefore also false; wherefore equal amounts of heat and water are *not* expended in the generation of equal power, when the steam is used at different pressures.

In this same section, (page 55,) the author tells us that

"By knowing the evaporation from the boilers, and consequently, the weight of water as steam which passes through an engine, we grasp the principal fact of practical consequence to the engineer; a fact which is free from all uncertainty in its nature; . . . . . . and the weight of water, which has passed from the boiler in that state, and produced a given effect, appeals conclusively to the understanding as indicative, in a comparison of engines, of their respective economy in the expenditure of power."

This does not seem very consistent with what he says on the subject in the first section, (page 52,) where, speaking of this method of determining the power of engines, he observes, that "as its value depends on a perfect accordance between the results of experimental and practical science—an accordance yet unascertained,—and since many precautions are requisite to secure true results from this test, it has been seldom resorted to by practical men."

The discordance between these two quotations is most remarkable, and the paragraph which follows the latter leaves no room to doubt that the basis of the method there alluded to is the identical fact which he says is *free from all uncertainty in its nature*, &c.

In the table already alluded to, (table 6,) will be found many results computed from the data furnished by experiment, which, if correct, will be of great practical utility to the engineer. Among these may be mentioned the weight of water as steam equivalent to the production of a horse power in each engine, and also, the duty effected by one pound of steam. "These sums, (columns 11 and 16,") the author observes denote the positive and relative *efficiency of steam* in the different "engines;" and here we recognize the pen of Mr. Parkes in the signification he gives to the word *relative*, it being here used to express the *inverse* of positive. Thus the *relative* efficiency of the steam *decreases* in precisely the same ratio as its *positive* efficiency *increases*, which we find difficult to comprehend with our preconceived notions of the meaning of the word *relative*. We should have thought, for instance, that if the *positive* efficiency of the steam in a given engine were equal to a, and in a second engine to b, its *relative* efficiency in the first in comparison with the second would be $\frac{a}{b}$, and that if, the positive efficiency b, remaining the same, that if the engine were increased from a to $2\,a$, its *relative* efficiency would also, be increased from $\frac{a}{b}$ to $\frac{2a}{b}$, or in the same ratio as its *positive* efficiency, The true *relative efficiency* both of the steam and of the fuel is however, given in columns 21 and 22, under the head *Comparative economical results.*

The next section, which treats *of the proportion of boilers to engines*, in our opinion serves rather to confuse and perplex the reader, and to deprive him of confidence in the numbers set down in the table, than to render him any assistance in drawing practical conclusions from them. We had intended to make a few observations on particular parts of this section; but having vainly endeavoured to follow the intricate reasoning of the second phragraph, and finding nothing of any importance in the rest, we shall merely direct attention to column 20, which will appear on the slightest examination to throw no light whatever on the economical qualities of either boilers or engines.

In the *observations on the experiments and their results*, which follow this section, there is nothing worthy of notice before the 61st page, from which we quote the following paragraph, in order to shew how necessary it is to sift *with the utmost care* all the results tabulated in this work.

"It is necessary, also, to guard against conclusions which might be deduced, from a comparison of the effects of the Cornish engines in the table, with the pressures on the piston and degrees of expansion, set down in columns 5 and 6. The pressures given were not ascertained by any instrument, (excepting at Huel Towan,) and must be considered only as estimations, not as facts. The pressure upon the piston during the interval which occurs between the first admission of steam into the cylinder, and the instant of shutting it off, may be very variable; that it was so, in several engines to which Mr. Henwood applied the indicator, is evident from the diagrams he has given, annexed to his paper. (Trans. Inst. C. E. Vol. II.) At the Huel Towan engine, when the steam in the boilers was at a pressure of 17·4 lbs. above the atmosphere, it varied from 12·3 lbs. to 7·3 lbs. per square inch on the piston, during its admission into the cylinder; which latter was its elastic force, at the instant of closing the steam-valve. I adduce these facts, with the view of showing the impossibility of determining the precise amount of prssure on the piston, from the degree of *wire-drawing* the steam; and as a caution against expectations of deducing any valid theory of the action of the steam, in these Cornish engines, from the particulars of pressure and expansion, contained in the table, which are only approximations to the truth."

Mr. Parkes does not seem to have compared the numbers contained columns 6 and 14, otherwise he never could have considered the above caution necessary; for the anomalies which would be found to result from the adoption of the numbers there set down are so striking that it would soon be discovered that either the pressure of steam on the piston, or the consumption of water as steam is incorrectly given; and it would certainly not occur to any one to deduce any theory of the action of the steam from such conflicting data. A superficial examination of experiments 7 and 9 will give an idea of the confidence which can be placed in the numbers contained in the table.

The diameters of the cylinders of these two engines are equal, but the latter has four inches greater length of stroke; the steam is also admitted into the cylinder of the latter during one-fourth of the stroke, while in the former it is cut off at one-fifth; but, since the latter only makes 4·29 strokes per minute, while the former makes 5·35, the volume of steam consumed in an hour should have been about equal in the two experiments. Now the pressure of the steam before the expansion is given as 7·3 lbs. per square inch in the former case, and 27 lbs. in the latter case, above the atmosphere, and the volume of steam generated from a given volume of water under these two pressures is respectively proportioned to the numbers 1173 and 653; the consumption of water as steam must therefore be nearly inversely as these two numbers, and taking the consumption per hour in the former experiment at 2156·21 lbs., as in the table, the consumption in the latter experiment ought to be about 3873·25 lbs., whereas it is given in the table as only 972·62, or very little more than one-fourth part of what it ought to be. We conclude from this that the numbers set down in column 6 are of no value whatever, as they do not appear to represent the true pressure on the pistons: nor indeed is it probable that the steam should lose so much as 12 lbs. of its pressure in passing from the boiler to the cylinder, as in the case of the Huel Towan engine, experiment 7. (See columns 6 and 7.) If *wire-drawing* is really carried to such an extent in the Cornish engines, it is a proof of sad mismanagement; for, if it is necessary to throttle the steam to such a degree, in order to reduce it to the desired pressure in the cylinder, it is very evident that the load on the safety-valve might be diminished, and the steam thus generated at a lower temperature, the advantages of which are too obvious to need pointing out here.

Mr. Parkes does not seem very confident of the advantage of the Cornish (expansive) system of using steam in manufacturing engines requiring uniformity of motion, and seems to approve of the method recommended by Mr. Wicksteed in such cases,—(see the Journal for January,) namely to employ a Cornish engine to raise water up on a wheel, and thus transfer its power to machinery. Now, although the momentum of such machinery is but trifling, an equivalent is easily found in a fly-wheel, and the want of uniformity in the action of the steam is probably not so great as may be supposed.

We agree with the author that the *pound of water as steam* consumed by an engine is the most convenient and correct standard of duty which can be adopted, provided we know the true quantity of water which passes through the engine in the form of steam.

The first division of this work is concluded with a chapter *on the Constituent Heat of Steam*, in which the author describes a series of experiments made by himself, the results of which confirm the already generally admitted law, that equal weights of water absorb equal quantities of heat in passing from the liquid to the elastic form, under all pressures.

The remaining portion of this work, which treats *of the Locomotive Engine*, being very long and perplexing, we have not sufficient leisure to enter into a detailed examination of all the difficulties and doubts, opinions and arguments contained in it; we must, therefore, content ourselves with a few general remarks.

The greater part is occupied by an examination of the experiments of M. de Pambour, Mr. Robert Stephenson, Mr. Nicholas Wood, and Dr. Lardner; the object of this examinution being apparently to convince the reader of the inaccuracy of *some of the results* of experiment, and of *all the deductions* hitherto drawn from them, and to prepare him for the reception of a *new theory* of his own, which he lays down in a separate section near the end of the work.

It is very certain that the experiments hitherto made on locomotives are too few in number, and too imperfect in their nature to allow of any certain theory of their action being as yet deduced from them; but on the other hand we have no doubt that a careful investigation of Mr. Parkes' objections would bring many fallacies to light, which might otherwise have the effect of unjustly shaking our confidence in the results previously obtained and published by other authors. As an instance we shall merely cite the comparison he has instituted between two of M. de Pambour's experiments, (pages 95 and following,) which were made with the same engine (Atlas) at two different speeds, and with corresponding loads. Mr. Parkes, in his detailed calculation of the effects produced in these two cases, omits, without assigning any reason for so doing, to include the pressure on the back of the piston, which is undoubtedly a part of the resistance, and therefore the power expended in moving this resistance at the velocity of the piston, is a part of the gross power of the engine, or of the total effect of the steam. With this omission Mr. Parkes finds the absolute (or gross) power of the steam equal to 67·11 horse power in the first case, where the velocity was 20·31 miles an hour, and 59·50 in the second, where the velocity was 27·09, (See page 95.)

In these two experiments M. de Pambour gives the same effective evaporation, namely, ·77 of a cubic foot of water per minute; and it is to prove the impossibility of this fact that Mr. Parkes made the above comparison; for he observes (page 99); "To be consistent, however, with his own (M. de Pambour's) rule above quoted, viz. that 'the weights of water consumed as steam are to each other as the resistances against the piston,' it is obvious that if, in the first case, 3026 lbs. of steam passed through the cylinders in an hour, 2166 lb. only would have been expended in the second case." Now this assertion is not even justified by his own calculations, for M. de Pambour evidently did not, nor could he mean to say that the weight of steam which passes through the cylinder in a given time is proportional to the resistance, whatever may be the speed of the engine, which would obviously be absurd, but that the density of the steam, and therefore the weight which passes through the cylinder in a given number of strokes, or which is the same thing, in travelling over a given distance, is proportional to the resistance. The consumption of water in a given time would thus be directly as the product of the resistance by the velocity, or the gross power of the engine; so that, if this power is equal in the two cases, so ought also the evaporation per-minute.

The effect of the steam in overcoming the resistance of the atmosphere on the opposite side of the piston is equal to 25·25 horse power in the first case, and to 36·77 in the second, which, added to 67·11 and 59·50, found by Mr. Parkes, respectively give 92·35 and 96·27 horse power as the gross effect of the steam in the two cases. The near coincidence of these two numbers shews that in this case at least there is no validity in Mr. Parkes' objections. We should therefore recommend a most diligent and patient examination of this section, before the adoption of any opinion therein expressed, or the rejection of any others previously entertained,

We have already alluded to a *new theory of the locomotive engine* proposed by the author of this work: the section in which he explains this theory commences (page 124) thus:

"Of momentum as a measure of the effect of locomotive engines.

"The effective power of a locomotive engine—by which is meant the excess of power after overcoming its proper friction, and the resistance from the blast—is solely expended in the generation of momentum. The momentum communicated to the entire mass set in motion represents the useful mechanical effort exerted by the steam; this effect of the engine is, therefore, at all times determinable; for, being the simple product of the mass moved, multiplied into its velocity, it is the product of two quantities easily ascertained under all the practical circumstances of railway traffic. The consumption of power, as water in the shape of steam, is a third quantity also readily appreciable.

"Were it possible to work a locomotive engine and its train *in vacuo*, on a truly level plane, the momentum generated by an equal expenditure of power would be a constant quantity at all velocities; for, the resistance being invariable, equal momenta would be produced by an equal expenditure of power with all loads, as the velocity attained would be in the inverse ratio of the loads, and vice versâ. This hypothetical case supposes friction and resistance of all kinds to be constant."

This is not only a *new theory* of the locomotive engine, but one which involves a *new definition* of the word *momentum;* for, according to the present acceptation of the term, momentum can only be *generated* during an acceleration of the moving mass, which accelleration is not, and ought not to be considered in locomotives, unless the time in which a given accession of velocity is also taken into account at the same time, which is evidently not contemplated by Mr Parkes. What is here understood by the *momentum generated* in one second, is nothing but the *absolute momentum* referred to the second, as the unity of time, which is deduced from the *uniform velocity* of the engine, without reference to the time in which it acquired that velocity.

Since the resistance does not enter into this expression of the power of the engine, it would follow that the same engine would draw the same train at the same velocity, whatever the nature of the road may be; since the evaporation being the same, the power expended must be the same; and since the mass moved is the same, so must also its velocity, to make its momentum equal. The absurdity of this doctrine is obvious.

The next section contains some good observations on *the blast*, as well as some experiments made by the author on *the resistance produced by it;* but no reliance can be placed in the results there recorded, some of them being evidently impossible. At page 147 we read the following:

"The immediate cause of my entering on these experiments is worth mentioning. I one day observed the mechanic in care of the machine, whilst preparing for work, opening and shutting the grease cocks of a cylinder, and giving oil to a piston. The engines were then working without load, and it was evident that a small vacuum existed after the blast, or the oil would have been blown back instead of entering the cylinder. This fact, the possibility of which had not before struck me, induced me forthwith to order another gauge from Mr. Adie, which was fixed on one of the blast-pipes, in a convenient place for constant observation, about 2½ feet from its junction with the cylinder, the bulb being exposed to the full current of the escaping steam. This instrument detected the fact of a vacuum by marking, usually, a temperature of from 208° to 210°, or about 1 lb. per square inch below the atmospheric pressure, the active steam on the piston being 1½ lb. above it. When the engine was driven at double velocity, or at 120 revolutions per minute, at which speed it required about 3½ lbs. of steam, the thermometer rose to 211°, and when locomotion was given to the machine at the usual velocity of 60 revolutions of the crank shaft, and requiring 4 lbs. in the boiler, the blast thermometer stood at 212°, exhibiting a pressure equal to the atmosphere only. At 8 lbs. on the piston, a counter pressure of about 2 lbs. was exhibited, at 15 lbs., about 4 lbs., and at 20 lbs. the blast thermometer indicated 6 lbs., beyond which point I was unable to load the engines."

In his observations on M. de Pambour's experiments (page 87), Mr. Parkes justly remarked that a *vacuum* on the opposite side of the piston was *an impossible result*, and this remark evidently holds good for his own experiments as well as his deduction from those of M. de Pambour.

In conclusion, we would again caution our readers against adopting the conclusions arrived at by by Mr. Parkes without first submitting the whole of his work to the strictest scrutiny. There is some, and there may be much good in it; but, having detected errors of importance in some parts, we cannot depend on the correctness of that which we have not had time to inquire into.

Very great merit is however due to Mr. Parkes for the indefatigable zeal he has exhibited in the compilation of data, and in the comparison of results therefrom deduced, which must have cost him much time and labour, with the praiseworthy object of advancing our yet imperfect knowledge of the effects and comparative economy of steam engines.

The Royal Lodges in Windsor Great Park, *from Drawings by* H. B. Ziegler, *executed by* L. Haghe, *in lithography, by express command, for Her Gracious Majesty Queen Victoria.* Folio. Ackermann.

If by "express command" we are to understand more than a mere permission, all we can say is that we cannot possibly compliment "Her Gracious Majesty" upon her taste, for while considered as drawings, the plates are far from rivalling preceding specimens of lithography, as architectural subjects they are very much more unsatisfactory. Indeed it seems to have been taken for granted that the less that was said about these buildings the better, there being no description or information of any sort attached to the plates; therefore, not happening to be acquainted with their history, we are unable to say who was the perpetrator of these Cockney whims and monstrosities—tasteless jumbles of cottage, castle, and what not, without a single redeeming merit of any kind, downright paltriness, and utter want of feeling for any one of the styles thus attempted, being their chief characteristics.

Scarcely can we bring ourselves to believe that Sir Jeffry Wyatville was concerned in the erection of this architectural trumpery; and if not, he would do well to clear himself from a suspicion which is very likely to attach itself to him, as the Royal architect at Windsor. Let the designs have been by whomever they may, they ought never to have been executed; and it fills us with concern to behold—emanating from what ought to be the fountain head of taste, such specimens of it as would be excusable only in some suburban tea-garden. But for their feebleness they might pass for arrant caricatures.

Arboretum et Fruticetum Britannicum; or, the Trees and Shrubs of England. By J. C. Loudon, F.L. and H.S., &c. London: Longman and Co., 1839, 8 vols. 8vo.

The name of Mr. London suggests the idea of a work of great extent, of great labour and research, but that now before us surpasses any of his previous triumphs. It bears less the impress of an individual production than of a national work, a character sustained by the number and value of its contributors, and by the eagerness with which all ranks devoted themselves to the promotion of a task so noble. The man of science hastened to contribute from his stores of knowledge, the grandee and the gentleman threw open their rich collections, or volunteered at their own expence to obtain illustrations for the work. From the duke downwards every patron and amateur of horticultural science seems to have considered co-operation in the work a duty and a pleasure. This detracts not from the value of Mr. London's labours, it enhances them, and is a high proof of the estimation in which they are held.

This work, as it professes, gives a pictorial and botanical delineation, and scientific and popular description of the native and foreign, hardy and half-hardy trees and shrubs of England, with their propagation, culture and management, and their application in landscape gardening. To the landscape artist trees have the same importance as details of style have to the architect, and every artist and amateur is, consequently under an obligation to possess himself of this encyclopædia of the art. The letter-press in the old times might legitimately have been spun out to twenty volumes; the engravings our fathers could never have compassed, they are two thousand five hundred in number, and are executed from drawings by the Sowerbys, and other botanists of distinction. We have only one fault to find with the work, and that is, that we see it disfigured with a barbarous Latin name.

To give extracts from these volumes would be indeed to realize the old Greek apophthegm of showing a brick for a house, so that we must content ourselves with expressing our feeling of the value of Mr. London's labours, and with recommending this admirable work to all who wish to follow with success an art so grand, as that of landscape gardening.

Elementary Principles of Carpentry, illustrated by 50 engravings and several wood-cuts. By Thomas Tredgold. Third edition, with an Appendix, by Peter Barlow, F.R.S. London: John Weale, 1840.

This is a new and improved edition of Tredgold's work, and Mr. Barlow bases his chief claim for its value as much on the proper retention of the original matter, as on the excellent additions which he has appended to it. These accessions are so important as to make the new edition desirable even to those who possess the work in its original form. Among many excellent specimens of Foreign and English roofing now introduced from the highest sources, may be particularly mentioned the information given relative to that admirable work King's College Chapel, drawn by Mackenzie, and St. Dunstan's Church, Fleet-street, by Shaw. The drawings of the iron roofs executed by the Butterley Iron Works Company are no less interesting, as well as those of several new buildings in London. We do not, however, so much admire the roof of the Exchange at Genoa, it strikes us as showing more ingenuity than science. We shall probably notice this work more at large next month.

An Essay on the Formation of Harbours of Refuge and the Improvement of the Navigation of Rivers, by the adoption of Moored Floating Constructions as Breakwaters. By John White, Architect, London.

Mr. White has long been an advocate for the application of floating breakwaters, and we think that he appeals successfully to his readers, considering that their own experience on any common river must have convinced them of the efficacy of such a mode of protection. With the application of Mitchell's Mooring Screw and the new Wire Cable, we see no difficulty in carrying out Mr. White's plans both efficiently and successfully.

We feel indebted to the author for the tribute he has paid to our exertions and those of our correspondents, in promoting such an important branch of engineering as harbour construction, but no feeling arising from this tribute, influences us in the expression of our sentiments of the high value of this work.

THE RIVER BOURN, OR INTERMITTING SPRING OF THE NORTH DOWNS.

The bursting or breaking out of the Bourn water about two months since excited some attention at the time, on account of the interval elapsed since its last eruption in the early part of 1837, being shorter than usual, but now (Feb. 16,) that the waters have continued to flow with increased volume, and having flooded the valley through which it passes, together with the lower part of Croydon, called the Old Town, and the turnpike road, it has become a serious inconvenience. This intermitting spring is situated in the great chalk range which stretches in an east and west direction through the south-east of England, called the North Downs, in distinction from the parallel chalk range near Lewes and Brighton, called the South Downs. A traveller taking the high road from London through Croydon to East Grinsted and Lewes, would pass along the valley through which the Bourn water runs. A little to the south of Croydon, the chalk rises from beneath the London and plastic clay formations (its dip being northwards), and with comparatively slight undulations, it attains the height of 800 feet above high water level, within a distance of eight miles to the south of Croydon, the summit being 667 feet above that town.

The first appearance of the Bourn water is in a flat part of the above valley, just below Birch wood house, and is situated between the Half Moon Inn at Catterham Bottom, and the Inner entrance to Marden Park, where it bubbles through the surface of the ground in an almost infinite number of jets, some of them are extremely small, and none more than a quarter of an inch diameter; about twenty yards from the highest of these jets their number is sufficient to form a rivulet, and in 100 yards a very considerable stream, and where it reaches Catterham Bottom, about three quarters of a mile, it may be called a river; the height of the first outburst is 350 feet above high water, from thence it flows northward to Croydon, where it is 133 feet above the same level, therefore its descent from the source to Croydon, is 217 feet in a distance of six miles, or an average of 36 feet per mile, consequently its current is very rapid. Its present eruption has been much greater than any that can be remembered by the oldest inhabitants of the district. The writer witnessed that in 1837, it was confined to the channel which from time immemorial was prepared for it, and which at Riddlesdown (about half way between its source and Croydon,) is about 6 feet wide and 5 feet deep, commonly called the dry river, from its being free from water so long; in the present instance the water has exceeded these limits, and covered the whole of the valley in many places three and four feet deep, and where it crosses Smithern bottom, it has stopped the works of the Brighton railway, that being the point where a deviation of the present Godstone road is to be made, and a bridge erected to carry the railway over the deviated road; the materials for the bridge are all upon the ground, and the embankment, which is to reach to the bridge, is brought nearly as far as it can with propriety before its erection, consequently, these works are stopped till the Bourn ceases to flow.

The cause of this curious phenomenon is, no doubt, the same as describ d in philosophical works under the head of intermitting or reciprocating springs, from which it appears that the water which falls upon the surface of the ground, percolates through the various strata, until it is stopped by one which is impervious, or it falls into cavities where it is collected as in a reservoir; this continues until the waters have accumulated to the filling of the reservoir, when it finds an outlet in the form of a syphon, consequently, it will continue to flow till the reservoir is empty. It would therefore appear that the short interval since the last eruption of the Bourn, has been occasioned by the almost unprecedented quantity of rain which has continued to fall for many months past.

Connected with this subject, there is a mine about three miles to the south of the source of the Bourn, in which water began to collect last autumn, and the miners were driven thereby from several of their headings in September last, and it appears that such circumstance always precedes the bursting of the Bourne, and the workmen confidently predict that event.

The works in the Merstham tunnel on the Brighton railway, which is being made through the same chalk range, and scarcely four miles west of the Bourn, have been much retarded, and now nearly suspended, by the quantity of water which has come in upon them; what few men are able to reach their works, are at the present time floated upon rafts from the shafts to the top headings, which alone they are able to drive; previous to this outburst, the tunnel was perfectly dry, and it may therefore be attributed to the same cause as the Bourn water itself.

PROGRESS OF RAILWAYS.

Greenwich Railway.—Thursday morning, 30th January, at half-past ten o'clock, a serious accident, and one that might have been attended with the most fatal results, occurred on the Greenwich Railway. Two Greenwich trains were coming up to town,—the first being the ordinary passenger train, the second one engaged to bring up a detachment of the Royal Artillery to the Tower. A Croydon train was coming at the same time from London, but before it could turn off to take the line that branches off to Croydon, it came into collision with the Greenwich passenger train, and the train with the artillerymen coming up almost immediately, the three trains got jammed together. The Greenwich train was thrown off the line, and several of the passengers injured, but none fatally. Major Boyce, of the Artillery, was severely cut about the head and face, as was a gentleman belonging to the Admiralty.—*Morning Post.*

Great Western Railway.—It is understood a single line of rails on the Great Western Railway from Reading to Twyford will be opened as soon as possible, so that the traffic by single trains should commence at a very early period. To accomplish this end, the works are proceeding day and night whenever the weather permits, but the rain has been a frequent impediment to the workmen.—*Wiltshire Independent.*

Manchester and Leeds Railway.—The Directors have just made their monthly inspection of the works, which are progressing most rapidly. Some idea of the exertions used to push forward the undertaking, may be formed from the fact that Mr. John Stephenson, the contractor for the great tunnel, which is far advanced towards completion, has now in full operation, on that contract alone, 1,253 men, 54 horses, and 14 steam-engines; and that the daily consumption of bricks is from 51,000 to 60,000.—*Railway Times.*

Progress of the North Midland Railway.—A considerable portion of this railway is so far completed as to allow of the permanent way being laid; this is done on the greater part of the line. The most forward district is that situated between Derby and Barnsley. One line of rails is now nearly all laid for the whole distance, which is about 50 miles; great exertions having been made to accomplish this, as it is expected the directors will pass along the line with a locomotive engine, between the towns of Derby and Barnsley, very shortly—probably next week. In the neighbourhood of Belper, Clay Cross, Staveley, &c., the works are proceeding night and day, in order to have a road through the large excavations in those districts. The first class stations are nearly all contracted for, and several of them are in a forward state. The Eckington one is nearly ready for the roof; the Chesterfield and Southwingfield stations are also far advanced; the Leeds and Sheffield stations have been set out during the week. The latter one is contracted for by Mr. Crawshaw, and will be situated near the entrance of the Sheffield and Rotherham Railway. It will be a large and convenient station; the cost is estimated at about 8000*l.*—*Sheffield Iris.*

South Western Railway.—A completely new town is in the course of formation between the old corporation of Kingston-upon-Thames (Surrey) and the South Western Railway, and already nearly two hundred beautiful houses, snug and aristocratic villas are finished, or in the course of finishing. From an inspection of the plans, and a view of what has been done, great taste and judgment appear to be exhibited; and the railway Company, from the advantages of its site over that of the old Kingston station, have been induced to remove it to the entrance to the new town, where a very commodious structure has been erected for the accommodation of the public. It is a singular fact, and one which must mainly contribute to the eligibility of New Kingston, that the first-floor windows of the houses command a view scarcely to be equalled in England, comprising no less than five Royal Parks—those of Hampton, Bushy, Richmond, Windsor, and Claremont, besides the gardens of Kew and the river Thames; and yet this spot, by railroad conveyance is only twenty minutes ride.—*Observer.*

STEAM NAVIGATION.

Launch of an Iron War Steamer.—On Thursday, February 6th, was launched from Messrs. Ditchburn and Mare's building yard, Blackwall, the *Proserpine*, wrought-iron steam vessel of 470 tons. She has four sliding keels, nine water-tight bulkheads, two of which are longitudinal running the entire length of the engine room—is armed with four long guns on non-recoil carriages, and will not exceed four feet draught of water when fully equipt for sea. The engines are two 45 horse, having the wheels to disconnect on a new and improved method to facilitate sailing, by Messrs. Maudsley, Son and Field. This vessel is constructed for sailing as well as steaming. It is a fact worthy of record, and ought to be generally known, that Messrs. Ditchburn and Mare were the first who arrived at the hitherto deemed unattainable result of giving highly superior sailing qualities to iron sea-going vessels of shallow draught of water. Their application and improvement of *sliding* *keels* have been most successful, their simplicity is such that a boy can manage them. Every person conversant with the history of naval architecture is aware that Captain Shanks, R.N. was the ingenious inventor, and that he received his first idea of them from the Indian navigating his raft, but although Captain Shanks, aided by the government of his day, made several attempts to establish their use in timber-built vessels failed, chiefly in consequence of the great difficulty in making the well and aperture through the keel, through which the sliding keel works, permanently water-tight; this in an iron vessel can be most perfectly accomplished. They are of the highest utility in the prevention of lee-way, counteracting rolling motion, and the vessel can be steered by them without the help of the rudder.'

Testing the strength of Iron Boats.—On Monday, February 24th as they were lifting from the wharf a 25 horse boiler of an iron boat, built by Ditchburn and Mare, the crane which was of cast-iron broke, when the boiler and crane fell a distance of 8 feet into the bottom of the vessel, little or no damage was done, and fortunately no one was hurt. This vessel is named the *Lee*, and has the reefing wheels after Mr. Hall's patent, we believe this to be the first application of them—we wish them every success.

The *Orwell* iron steamer, plying between London and Ipswich, made during the late gales several passages from London to Ipswich in seven hours, including the calling off Gravesend, at Harwich, and other stoppages, a distance of 112 miles.

The Sons of the Thames, of which vessel we made mention in our January Journal, came from Gravesend Pier to Blackwall in one hour and five minutes, a distance of 20 miles.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 30TH JANUARY, TO 26TH FEBRUARY, 1840.

Moses Poole, of Lincoln's Inn, Gentleman, for "*improvements in pumps for raising and forcing water and other fluids.*" Communicated by a foreigner residing abroad.—Sealed January 30; six months for enrolment.

William Brockedon, of Queen's Square, Middlesex, Esq., for "*improvements in the means of retaining fluids in bottles, decanters, and other vessels.*" January 31; six months.

Philippe Marie Moindron, of Bedford Place, Russell Square, Merchant, for "*improvements in the construction of furnaces and in boilers.*" Communicated by a foreigner residing abroad.—January 31; six months.

William Cubitt, of Gray's Inn Road, Builder, for "*an improvement or improvements in roofing.*"—January 31; six months.

Crofton William Moat, of Thistle Grove, Brompton, Esquire, for "*a new and improved method of applying steam-power to carriages on ordinary roads.*"—February 5; six months.

Wilkinson Steele and Patrick Sanderson Steele, Manufacturing Ironmongers, of George Street, Edinburgh, for "*improvements in kitchen ranges for culinary purposes and apparatus for raising the temperature of water for baths and other uses.*"—February 5; six months.

William Isaac Cookson, of Newcastle-upon-Tyne, Esquire, for "*certain improved processes or operations for obtaining copper and other metals from metallic ores.*"—February 5; six months.

Thomas Myerscough, of Little Bolton, and William Sykes, of Manchester, Machine Maker, for "*certain improvements in the construction of looms for weaving or producing a new or improved manufacture of fabrics, and also in the arrangement of machinery to produce other descriptions of woven goods or fabrics.*"—February 5; six months.

Samuel Carson, of Caroline Street, Coleshill, Eaton Square, Gentleman, for "*improvements in apparatus for withdrawing air or vapours.*"—February 5; six months.

Joseph Needham Tayler, of Plymouth, Captain in the Royal Navy, for "*improvements in steam-boats and vessels making applicable the power of the steam-engine to new and useful purposes of navigation.*"—February 8; six months.

John Wertheimer, of West Street, Finsbury Circus, Printer, for "*certain improvements in preserving animal and vegetable substances and liquids.*" Communicated by a foreigner residing abroad.—February 8; six months.

Robert Beart, of Godmanchester, Miller, for "*improvements in apparatus for filtering fluids.*"—February 8; six months.

Amand Deplangue, of Lisle, in the Kingdom of France, but now residing in Leicester Square, Gentleman, for "*improvements in looms for weaving.*" Communicated by a foreigner residing abroad.—February 8; six months.

Edmund Rudge, Jun., of Tewkesbury, Tanner, for "*a new method or methods of obtaining power for locomotive and other purposes, and of applying the same.*"—February 8; six months.

James Hancock, of Gloucester Place, Walworth, for "*a method of forming a fabric or fabrics applicable to various uses by combining caoutchouc, or certain compounds thereof, with wood, whalebone, or other fibrous materials, vegetable or animal, manufactured or prepared for that purpose, or with metallic substances manufactured or prepared.*"—February 8; six months.

George Eugene Magnus, of Manchester, Merchant, for "*certain improvements in manufacturing, polishing, and finishing slate, and in the application of the same to domestic and other useful purposes.*"—February 8; six months.

Robert Willis, of the University of Cambridge, Clerk, Tonksonian Professor, for "*improvements in apparatus for weighing.*"—February 8; six months.

David Napier, of York Road, Lambeth, Engineer, for "*improvements in the manufacture of projectiles.*"—February 12; six months.

Antoine Blanc, of Paris, Merchant, and Theophile Gervais Bazille, of Rouen, Merchant, now residing at Sablonieres Hotel, Leicester Square, for "*certain improvements in the manufacturing or producing soda, and other articles obtained by or from the decomposition of common salt or chloride of sodium.*"—February 12; six months.

Thomas Robinson Williams, of Cheapside, Gentleman, for "*certain improvements in the manufacture of woollen and other fabric or fabrics of which wool or fur form a principal component part, and in the machinery employed for effecting that object.*"—February 14; six months.

Joseph Clarke, of Boston, Printer, for "*improvements in piano-fortes.*"—February 14; six months.

Gerard Ralston, of Tokenhouse Yard, Merchant, for "*improvements in rolling puddle balls or other masses of iron.*" Communicated by a foreigner residing abroad.—February 22; six months.

Richard Cuerton, Jun., of Percy Street, Middlesex, Brass Founder, for "*improvements in the manufacture of cornices, mouldings, and window sashes.*" Communicated by a foreigner residing abroad.—February 22; six months.

Thomas Kerr, of Forecrofts Dunse, in the county of Berwick, Esquire, for "*a new and improved mortar or cement for building, also for mouldings, castings, statuary, tiles, pottery, imitation of soft and hard rocks, and other useful purposes, and which mortar or cement is applicable as a manure for promoting vegetation and destroying noxious insects.*"—February 22; six months.

William Cook, of King Street, Regent Street, Coach Maker, for "*improvements in carriages.*"—February 22; six months.

John Hanson, of Huddersfield, Engineer, for "*certain improvements in meters for measuring volumes of gas, water, and other fluids when passed through them, and in the construction of cocks or valves applicable to such purposes.*"—February 22; six months.

William Winsor, of Rathbone Place, Middlesex, Artists' Colourman, for "*a certain method or certain methods of preserving and using colours.*"—February 22; six months.

Job Cutler, of Lady Poole Lane, Sparkbrook, Birmingham, Gentleman, and Thomas Gregory Hancock, of Highgate, in the same Borough, Mechanist, for "*an improved method of cutting corks and constructing the necks of bottles.*"—February 22; six months.

William Brindley, of Northwood Street, Birmingham, for "*improvements in apparatus employed in pressing cotton, wool, and goods of various descriptions.*"—February 25; six months.

Thomas Buckvale, of Over Norton, Oxford, Farmer, for "*improvements in ploughs.*"—February 25; six months.

Thomas Farmer, of Gunnersbury House, near Acton, Middlesex, Esquire, for "*improvements in treating pyrites to obtain sulphur, sulphurous acid and other products.*"—February 25; six months.

John Wilson, of Liverpool, Lecturer on Chemistry, for "*an improvement or improvements in the process or processes of manufacturing the carbonate of soda.*"—February 25; six months.

Richard Kingdon, of Gothic House, Stockwell, Surrey, Surgeon, for "*certain improvements in apparatus for the support of the human body, and the correction of curvatures and other distortions of the spine of the human body.*"—February 25; six months.

Thomas Milner, of Liverpool, Safety Box Manufacturer, for "*certain improvements in boxes, safes, or other depositories for the protection of papers or other materials from fire.*"—February 26; six months.

William Morrett Williams, of Bedford Place, Commercial Road, Middlesex, late of the Royal Military College, and Professor of Mathematics, for "*an improved lock and key.*"—February 27; six months.

TO CORRESPONDENTS.

In our last Number we inserted a drawing and description of the Traversing Screw Jack, but we omitted to state that it formed part of Mr. Curtis's *patent inventions.*

We shall be happy to receive from Mr. Armstrong, our valuable contributor, the proffered illustrations alluded to at the conclusion of his communication in the present month's Journal.

Mr. Thorold's new frame for Steam Engine, we were compelled to postpone, together with several other communications for want of space, we will endeavour to meet the wishes of our numerous contributors next month.

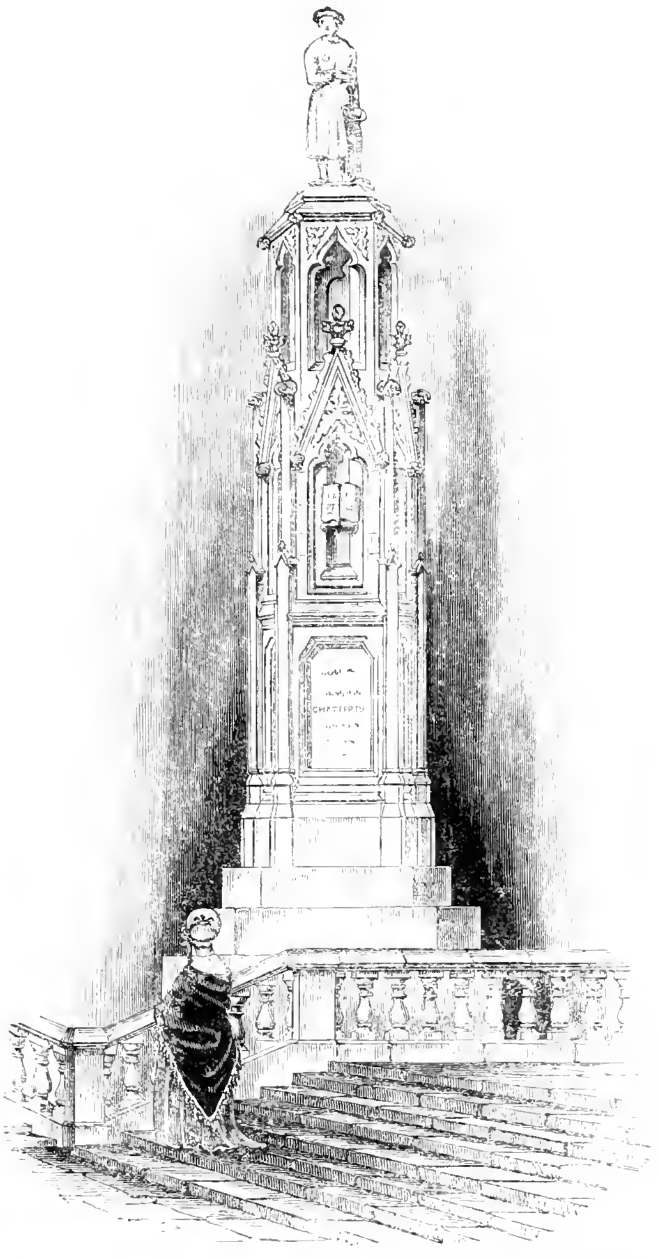
Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster, or to Mr. Groombridge, Panyer Alley, Paternoster Row; if by post, to be directed to the former place; if by parcel, to be directed to the nearest of the two places where the coach arrives at in London, as we are frequently put to the expence of one or two shillings for the* porterage only, *of a very small parcel.*

Books for review must be sent early in the month, communications on or before the 20th (if with wood-cuts, earlier), and advertisements on or before the 25th instant.

The First Volume may be had, bound in cloth and lettered in gold, Price 17s.

*** The Second Volume may also be had, Price 20s.

MONUMENT TO CHATTERTON.



Admiration of Chatterton, and compassion for his untimely fate have too often evaporated in mere declamation, and it wanted the spirit of a few individuals, and the talent of a disinterested artist to give the poet that tribute, to which every one acknowledged his title "The wonderful boy who died in his pride," the bard who gave Bristol that title in the literary world, which has since been maintained by Southey, had a right to expect from his fellow citizens a memorial which they had money to pay for and native talent to execute—The Bristolians have shown good feeling in preserving in the museum of the Institute the Eve at the Fountain, and they would have shown still more, had they employed the pencil of Lawrence or the chisel of Baily upon a subject so worthy of their talents, as the commemoration of a fellow townsman.

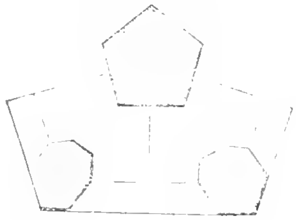
To enter into a biography of Chatterton would be misplaced here, while the leading incidents need but to be alluded to to recall the remembrance of his life, his childhood,* his relationship to Redcliffe his education in the neighbouring charity school, and his years of fretful toil as an attorney's clerk, are circumstances of local interest connected with the present monument No site could be better chosen than one near the place of his birth and of his literary education, no garb could be more dignified than that which recalled the difficult position from which he had to emerge to distinction. It was within the walls of St. Mary's that he breathed the inspiration of his song it was there that he planned the tale of fiction which struck the literary world with wonder, it was there that he placed the stage on which the imaginary Rowley was to herald the fame of Chatterton. The discovery of the fiction is not to be regretted, it is only painful as it led to the self destruction of one so promising and so talented, and the loss of a life which beamed with hope of better works. His fellow citizens have been loud in sounding his fame, but half their duty was undone while they left the tenant of the workhouse ground in Shoe Lane, without a stone to tell his name.

The people of Bristol have at last been alive to the claims upon them, but it is owing neither to their public spirit nor their generosity that the memorial is worthy of its subject. The paltry sum of one hundred pounds is what this rich city awards to commemorate its own glory, and that of its favorite son, and it is fortunate that the performance was not as mean as its reward. The monument, of Bath stone, is a Gothic cross, 31 feet high, bearing the statue of Chatterton, attired in the garb of the charity school in which he was brought up. The plan is pentagonal throughout, and harmonises with the rich architecture of the majestic church. The niches and tablet recesses are formed by alternate parallel surfaces with the face and side of the buttresses, as under:—

Plan of compartment in the middle stage of the Monument.
Scale ½ an inch to a foot.

The upper stage which is not shown minutely in our engraving is composed of five angular shafts detached from the central pier which supports the statue; the light and shade are therefore much more varied.

Plan of compartment in the upper stage of the Monument.
Scale ½ an inch to a foot.



There are five inscriptions on the tablets in the lower stages, and the open book and the scroll in the hands of the statue are also inscribed, the two latter in Old English character. The work is well executed, the carvings in particular, which are designed after some of the fine models in Bristol Cathedral.

The monument was sure to excite interest from its locality, and this interest has been maintained by the skill with which the work is made to harmonize with the noble back-ground formed by the North Porch of the church, rich in all the luxuriant ornament of the fourteenth century. It is to Mr. S. C. Fripp, jun. an Architect of Bristol, that the public are indebted for this admirable work, and he has shown both judgment and true genius in preserving that harmony of tone, which was dictated by a due regard to the proper treatment of the subject. Had Mr. Fripp done otherwise he would have stepped beyond his proper sphere, and failed in producing a work which does him so much honor. He has by this monument added fresh interest to a time honored site, given his native city a new ornament, and a noble bard his long neglected tribute.

* Thomas Chatterton born 1758, died 1770.

ON DAGENHAM BREACH.

A brief account of the stopping of Dagenham Breach on the Thames digested from Captain Perry's *Narrative, published at London in* 1721.

Engineering has only within the last fifty or sixty years been considered a liberal profession in Great Britain. Formerly from its limited extent, and the want of education and science on the part of its professors, it was looked upon as a subordinate although an useful occupation. Although the profession has so greatly extended itself within that limited pe iod as now to be recognized as a scientific avocation, we must not on that account suppose, that formerly there were not men engaged in its arduous works, who by their originality and boldness may be considered as worthy of memory. The work of which we are to subjoin a brief account was (like some others at the same period) conducted by a man of real genius and industry—one who although obliged by the slight encouragement given to his profession, to execute by personal *contract* the works which he designed, yet cannot be regarded as a mere pecuniary adventurer. Of his history all the information I have been able to gain has been gleaned from his writings, from which it would seem, and it is worthy of remark that his own country afforded such small scope for his genius, that he was obliged at one time to seek a livelihood under the Czar of Muscovy.

With regard to the work by which he so much distinguished himself, it was one of those unpretending yet costly works, the call for which, had it not been irresistible would have probably been disregarded, but it was a work that could admit of no delay, as every lost opportunity added to the difficulty of its completion. And it is to this cause we must attribute the laying out of such a large sum of public money in times so deficient of the spirit of enterprise.

Breaches in the Thames seem to have been of frequent occurrence in the earliest periods of which we have accurate accounts. So far back as the time of the Romans, the Thames afforded employment for the ingenious. The earliest work of which we have any information, was the drainage of Southwark and its neighbourhood; this was a sort of work with which the Romans were well acquainted. Sir William Dugdale in his voluminous history of Embanking and Draining (fol., London 1772, p. 84, 2d edit.) mentions that "howbeit these banks being not made strong enough to withstand those tempestuous storms and violent tides which happened in September 1621, Cornelius Vermuden, gentleman, (an expert man in the art of banking and draining) being treated withal by the commissioners of sewers appointed for the view and repair of the breaches then made, undertook the work and perfected it; but such being the perverseness of those *as* were owners of the lands assessed by the commissioners to pay their proportions thereof—upon comp'aint therefore made to the said commissioners, he the said Cornelius in recompence of his charges had parcel of the said lands assigned unto him, which assignation was by the king's letters patent confirmed to him the said Cornelius and his heirs."

I can find no account of the extent of this breach or the manner in which it was stopped. Although from the handsome remuneration with which the services of this eminent fen engineer were rewarded, we must suppose his task to have been a formidable one.

The breach with which Captain Perry was connected, was occasioned by the blowing up of a small sluice or trunk, that had been made for carrying away the drainage water of the low grounds adjoining the banks of the river. The ditch which communicated with this sluice was at first not above 14 or 16 feet broad, so that had the accident met with the attention it deserved, all the trouble and expence consequent on stopping the breach would have been saved. Instead however of prompt measures being taken, the damaged sluice was in the first instance neglected, and it was not until the tidal water had greatly enlarged the gap that attempts were made to stop the breach; but by this time the water had scoured away the clay bottom, and began to act upon what our author calls "Moorlogg," and the gravel and sand beds which lie out a little way below the surface of the ground. Moorlogg is described as a vein of matted brushwood, with nuts and pieces of rotten wood interspersed. In these soft strata the scour proceeded with great rapidity, and baffled all attempts which were made to check its progress during a period of no less than 14 years. In that time the tiny ditch had ramified above a mile and a half into the land, and its main branch had attained a breadth of about 400 or 500 feet, and a depth of from 20 to 30 or 40 feet. By a computation made at the time, no less than about 120 acres of marsh land had been carried into the Thames by this tidal river. The ground thus excavated and carried into the river was composed of clayey ground moorlogg, about a foot or 16 inches of blue clay, and at the bottom gravel and sand.

Nor was the loss of sand by any means the most serious consequence connected with this inroad of the tide; a more important although perhaps less apparent evil was the injurious effects produced by so large a quantity of matter lodging both in the higher and lower reaches of the Thames.

The landowners were neither idle nor illiberal in their efforts to check the incursion. The method they adopted was contracting the channel to some extent by means of pile-work advanced from both sides, and when the stream was confined within a moderate channel they sunk old vessels and large boxes; these were backed on both sides by "*maunds*," or baskets filled with chalk, and bags filled with earth and gravel. All this was done during neap tides, that they might be able to make good the dam before the springs. Engaged in these operations were those in the vicinity, and all who had a direct interest in their success, and many lost their lives by the violence of the current which swept them away, and carried them into the Thames.

In spite however of all their activity and perseverance, the tide always succeeded in boring through below the obstructions which had been put in its way. With such violence did it act that on one occasion when they had sunk the "Linn" man-of-war and two other vessels, the first ebb of the tide swept them so completely away that there was not a fragment to be seen, and as Captain Perry asserts, "three days after there was upwards of 50 foot depth at *low* water wher› she was sunk." This depth, however, seems very extraordinary, and is surely overstated. He mentions another case which certainly gives a good idea of the force of the current (pp. 17, 18). "Another gentleman concerned (since my late stopping the breach) speaking of what had passed with them in their attempts, merrily told me that at one of those times when they had made a shut (or attempted to do it) by the sinking among other things, a large chest or machine upwards of 80 feet long, the next day afterwards the violence of the back water setting out of the levels upon the tide of ebb, worked so strong underneath the bottom of this machine that she bolted up at once above water, and discharging as she rose most part of the chalk and stones with which she had been sunk, drove directly with the current out of the mouth of the breach, whereat a gentleman standing by, who was a considerable landowner, and had been at great expense in the work, being much surprised, ran along upon the wall (or bank) on the side of the breach, and with great earnestness called out, stop him, stop him, oh stop him! this machine driving directly down the river, and sometimes sticking against the bottom and sometimes rebounding above the water again, when it came down in view of the shi s at Gravesend, they were alarmed at the unusualness of the sight, as it emerged out of the water sometimes with and sometimes athwart the tide, and as they ride pretty numerous there at that time, they were forced to sheer, some one way and some another to avoid receiving any mischief from it It drove from thence as far as the buoy off the Nore, and there run aground upon a shoal."

At a later period they succeeded in keeping in their places some vessels which had been sunk by driving piles on each side, but although a large quantity of chalk in bags and baskets had been sunk all round them, the tide still rose and fell within. So much were the public interested in the operations that a power was given to impress all chalk vessels that passed on the river, so that sometimes 10 or 15 freights a-day were delivered at the breach, which was actually reported to have in some measure retarded the London buildings. An extraordinary tide happening soon after, put a stop at once to the embargo on chalk, and to the works at Dagenham, by removing the whole structure which had been erected at such cost and labour.

Here all exertions on the part of the landowners naturally enough ended, and they would no doubt have made up their minds to abandon to the waters their unfortunate property, the value of which was not adequate to warrant a farther expenditure, had not the destructive effects of the silt lodging in the Thames arrested the attention of the House of Commons, which passed a bill in April 1714, for effectually stopping the breach at public expense, and this they farther extended to removing the silt which had been deposited in the river, and making good the adjoining banks. Captain Perry offered to execute the works for £24,000, and a Mr. Boswell for £16,500, which being the lowest offer was accepted.

Mr. Boswell was first to make piers and then sink 6 ponts or chests 60 feet in length, 30 feet broad, and made salient at each end like the starlings of a bridge. These were to be placed in the bottom 12 feet apart, and the spaces were to be made up with piles and other timber work.

In the chests were to be sluices which when shut down were wholly to exclude the water. But the gap was no sooner contracted by the piers than the current scooped out the soft bottom which was the cause of the miscarriage of all the former plans. Thus was Mr. Boswell's first plan completely set aside. He had then recourse to one enormous box, but whenever he attempted to contract the water-way, as certainly did the bottom wear and assume an irregular deep rutted surface, so that after all these schemes he was constrained to return to the old system of staunching the current by the sinking of ships, ponts, and bags of chalk. The only new feature which he introduced into the plan was the fixture of enormous hair bags filled with chalk (some of them 30 feet in length) to the vessels bottom, which bags it was expected would have adapted themselves to the form of the bottom, and thus preserved a closer connection than had been effected before. He accordingly carried out his scheme, having sunk two vessels and the large pontoon which he had previously made, and he also surrounded the whole fabric with enormous quantities of chalk. In addition to this he had placed in the banks a little below the breach, two sluices which were intended to have relieved the pressure, but which according to Captain Perry could not from their construction and level have been of any service. The very first tide after the vessels had been sunk, operated with such energy on the bottom, that the whole fabric was totally destroyed by the second day after. The vessels laden with chalk and rubbish were thrown up, and the enormous pontoon gave the finishing blow by starting up and tearing to pieces the pile work and planking.

Here ended Mr. Boswell's services, and the trustees appointed by the bill having nominated a committee, inspected the ground and drew up a report dated November 7, 1715. The following soundings taken by the committee and given in their report are as follows: "on the west side 20 feet below the works to the south, 40 feet deep. On the south side 20 feet from the stern of the Abindon (one of the ships sunk in the said breach, 30 feet. On the same side, 15 feet from the stern of the Recovery, (another ship) 18 feet. Ten feet south from the piles on the east side of the breach 18 feet. Between the ships and the piles on the west side 29 feet. Betwixt the works to the northward near the piles on east side 24 feet. At the end of piles on east side 19 feet. Fifty feet north from said piles 31 feet. Fifty feet farther north 50 feet. Twenty-five feet north of the piles on the west side 26 feet. Fifteen feet north from piles in west side 11 feet. Close to said piles on west side 20 feet. Coming about the piles to the southward we find these depths following, viz., 29, 24 and 18 feet."

What sort of settlement was made with Mr. Boswell does not appear from the narrative, but new offers were obtained. Captain Perry gave in an account of his scheme, which was this. To have a sluice made in the embankment with a trench connected with the backwaters. To drive a row of *dovetailed* piles across the gap, leaving their heads not more than 18 inches or 2 feet above low-water mark; so that in driving these piles little or no difficulty would be experienced from the current. Forty feet from the row of piles on either side a sort of low coffer-dam 18 or 20 feet broad, to be formed of piles and boarding, and to be filled with chalk to prevent the toe of the embankment from spreading. On the outside of these coffer-dams a wall of chalk to be made as a farther security. The dam itself to be composed entirely of earth, and in the course of the erection care to be taken always to shut the sluice when the backwater falls to the level of the top of the work. In this way there will at no time be a higher face for the water to flow over.

This was evidently a judiciously contrived scheme, and shows that the projector of it had a just conception of the nature of the difficulties he was to contend with, which were a soft, unstable bottom and a powerful current of water. He was well aware that a dam of the thickness he contemplated would easily sustain the *pressure* of backwater, although from its being composed of soft materials, he could not expect it to withstand the action of water rushing over it. Experience had proved that such materials as chalk could not from the large interstices necessarily existing between the pieces, form anything like a water-tight dam, and if they had, the softness of the bottom was enough to render such a plan impracticable. The first grand points were to secure the treacherous bottom, and make a heavy and water-tight dam. These difficulties were well provided for by the use of dove-tailed piles and a clayey soil. The second point was to prevent the ebb and flood tides from rushing over the top of the dam when it was in progress; this difficolty was removed by keeping the backwater constantly on a level with the top of the work.

After much communing and trouble on both sides, a contract was entered into with Captain Perry, who was to perform the works for £25,000, he being bound to advance £5000, and to expend that sum on the works, after which he was to be supplied by the trustees. If the work were unsuccessful, the £5000 was of course lost to Captain Perry, or, rather, to the friends who had advanced it. Should, on the other hand, the work be successful, but be rendered very costly from any unforeseen accident, he was to be recommended to the consideration of Parliament.

After all this had been settled, Captain P. seems to have been much annoyed by Mr. Boswell and a host of *mathematicians*, who declared his plan impracticable. He, however, came through their hands, according to his own account, *non sine gloria*, as well as through the ordeal of sundry examinations and meetings.

No time was lost in commencing the work; but the sluice, from the softness of the ground, was not carried to its contemplated depth, which incurred the necessity of another being made. From some cause or other matters seem to have been mismanaged, for it was not until the spring of 1717 that the second sluice was completed, and the breach was not stopped till June. For this tardiness he pleads several excuses, but he does not succeed in satisfying the reader as to his promptness. The time for completing the dam had now nearly approached, and his friends who had advanced the money, became impatient, and so importuned him to push on the work, that he allows he was persuaded to admit stuff of an inferior binding quality in the formation of the dam. A great deal of bad earth was also put in without his knowledge, when the men were working at night, and his assistants, five in number, seemed rather to conspire against him than to back him in any of his difficulties, so that what between grumbling friends, rebellious assistants, and an impatient public, he was constrained to collect together all the force he could muster in the neighbouring country, in spite of the high wages of 36s. per week. These labourers, assisted by men from the royal yards of Woolwich and Deptford, soon made a satisfactory difference in the appearance of the work, but a most unsatisfactory difference in its quality. Hitherto each tide's work had been made in offsets or scarcements, about 7 feet broad and 3 feet high, these supported by piles and planking on the side, and protected by reeds on the top, had been able to resist the action of the tide when it came in. One of the assistants, however, proposed during the neaps to set all hands to work and make a narrow wall of earth, unprotected by reeds or planking, and build it so rapidly as to get it above the level of the springs before they should come on, and thus at once to exclude the tide from the marsh. Captain Perry unfortunately gave in to this proposal, trusting to the tide's being of its ordinary height. There happened, however, an extraordinary tide, occasioned by a storm at N.W., which tide rose about 6 inches higher than the top of the little wall, and pouring over it, soon washed it down, and the water thus widening its inlet, rushed over in such volumes, that in the course of two hours the dovetailed piles were laid bare.

When Captain P. observed the tide rising with unprecedented rapidity (which it did), he heightened the little wall with piles and boarding set on edge on the top, but the water insinuating itself between the boards and the earth, led to the calamity we have mentioned, and which the Captain says was due merely to the fortuitous occurrence of an extraordinary tide. Men were employed in digging down the earth, and otherwise easing the passage of the water over the dam, as well at the first inbreak as at subsequent tides, by which means the violence of the current was speedily checked.

This accident, as might have been supposed, caused many reports about the general insufficiency of the work, and the erroneous principles on which it had been carried on. This did not, however, deter Captain P. from proceeding with the repair during the winter months, and in raising the dam this second time, he was a great deal more scrupulous about the quality of earth used in its formation, and in the end of June, 1718, "the tide was again turned out of the levels in the time of neap as before, only that the work, after the tides were turned, was now continued to be raised by set-offs with piles and boards, and well covered over at the top, so that though a thin body of water did several times pass over into the levels, it was easily let off by the sluices. The trustees now visited the work, and expressed themselves satisfied with the manner in which this part of the work had been accomplished. After their visit he dammed up the two canals communicating with the sluices, and any subsidence of the dam he at once made up with new stuff The work being now in an apparently safe condition, the Captain left for Dover, where he was to report on the Harbour, and on his return he was seized with ague, and when he was recovering, but was still confined, on the morning of the 30th of September, 1718, a message was sent to him conveying the mortifying intelligence that the tide had again demolished the work. In spite of his ague he at once visited the spot, and found the sluice dams standing and the sluices shut, and, in short, nothing done towards easing the passage of the waters. He immediately summoned as many hands to his assistance as the neighbouring country could, on such short notice, produce; but the water had made such havoc, that in six tides about a hundred feet of the dovetail piles, &c., were torn up and carried away, and in one place there was about 20 feet greater depth than there was before the work was begun.

How this accident occurred was for some time a mystery, but it subsequently came out that the watchman had, instead of attending at his post, been reviving his frozen carcase at a neighbouring beer shop.

By this time the Captain's funds had been greatly reduced, and he applied to the trustees for a remittance, which they, however refused and he was reduced to the necessity of canvassing his friends for further sums which was after some difficulty supplied. This was in February, and it was not till the winter had expired that the gap was squared and filled up and the tides were expelled for the third time on the 18th of June. He continued also to increase the height of the dam till it was two feet above the level of a high tide that occurred in November, occasioned by the conjoined effects of a great storm and the moon's being in perigee.

It appears from his statements that the works had left him in a sadly crippled state as far as regarded his purse, and he concludes by urging the trustees at least to make up his deficiency that he might be enabled to steer clear of his creditors. He says "If I may—now the work is completed and so many years (5) spent therein, be but freed from the debts and engagements into which it has plunged me, and set at liberty to offer myself upon some other work, whereby I may be of use to my country and have an opportunity of getting my bread; I shall cheerfully submit to whatsoever shall be thought fit as to any consideration or reward to myself." He further volunteers his services for the improvement of the ports of Dublin and Dover, reports on both of which he subjoins to his narrative. I cannot, from the want of access to proper data (occasioned by a casual visit to the country), take any step towards ascertaining in what way the petition of our author was received by the Trustees and the house of parliament, as such information is not contained in his own narrative, that he was in some way freed from actual imprisonment and allowed to go at large in the practice of his profession, seems evident from the book which he subsequently published. In the Bibliotheca Britannica there is mentioned in the short catalogue of his labours as an author "Proposals for the draining the Fens in Lincolnshire. 1727 fol. His death is said in the same book to have taken place in 1733.

I shall now conclude by explaining my reasons for thus having brought a condensed view of this half forgotten work before the public through the medium of these widely circulated pages. Many who might have taken an interest in the work have no opportunity of reading Perry's own narrative from its unfrequent occurrence; and from the somewhat incoherent and cloudy stile in which it is written, the reader is frequently a little puzzled to know exactly what the author would be at. Even the description of his scheme (simple though it was) is not by most readers to be apprehended by a single perusal. These reasons and the wish to make the name of the successful projector of so formidable a work, better known to the profession must excuse me for occupying so much valuable room.

——

STEAM VESSEL INQUIRY AND INQUISITION.

The labours of the Commissioners have at last brought to light the promised Shiloh, in the shape of such a bill, as was never before seen. and we sincerely hope will never be seen again. The abstract which we have perused is such as was to have been expected from its concoctors, and the sources from which they derived their ideas of legislation; the bill seems to be a cross breed between a French police ordonnance, and an excise or custom-house act of parliament. Such inspectors and such surveyors, and such modes of action, were never before contemplated in this country, at variance with the recognized laws of all sound economy, they are obviously at variance with the national character, and the interests of the empire. It is by unshackled industry and by that alone that this mighty empire has been created, and that it is to be maintained, and it is on the prosperity of steam navigation in particular that our strength depends, and the means of profiting by our resources. What therefore can exceed the insanity which proposes to place inventors and manufacturers under a yoke, which in every other country has fettered the progress of science, and retarded the advancement of the nation? What are we to expect when we see spies under the name of surveyors introduced not only into the workshops, but into the study, not to be contented by tampering with the machinery, but who must meddle with the very design itself. Men who are to constitute a new middle class between the manufacturer and the shipowner, who are to tell one what he is to make, and the other what he is to buy, who are to be censors of the noblest efforts of invention, and judges of last resort in cases where the most learned disagree. Do we believe that the plague introduced among marine engineers will fester among them alone without extending to every other class of engineers? We neither believe it, nor can others. It is what is done in France and what will be done here; the police will not stop till they regulate the working of the engine in the factory, as well as the progress of the steam boat on the water, and the locomotive on the rail. To denounce this to Englishmen is unnecessary, to name it is to point out its train of informers and penalties, and to insure its instant condemnation.

The motives which inspire this bill, can have no origin in common sense, they can proceed only from some hateful inspiration, and what that is it would be difficult to point out. The least excusable would be to enable a government, always in arrear of private enterprise, to pillage in other establishments for the maintenance of the new factory at Woolwich. We cannot believe that they would hesitate to do so, when they are regardless in every other point.

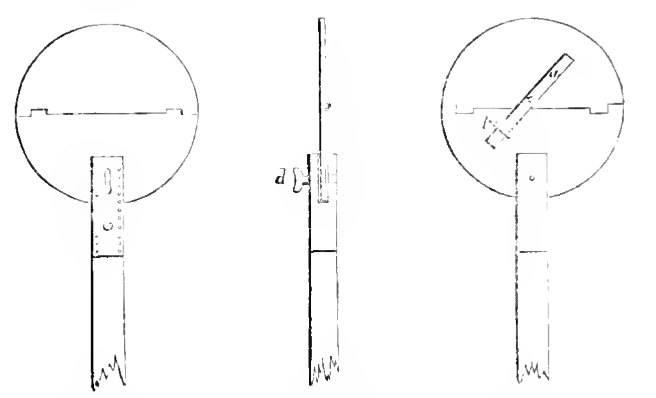
We felt it our duty to oppose this measure from its first suggestion, we have followed it with uncompromising hostility throughout its threatening progress, and we were not inclined to relax when we saw it assume a shape so formidable. Having issued a circular to the manufacturers, meetings have been held at which men, the first in talent, enterprise and wealth in the country have come forward to prove by their own conduct the justice of the course which we had pursued in their defence, and we trust that such an opposition is organized as will at least paralyze the operations of this obnoxious bill, if it do not destroy it in its birth.

We have on former occasions shown that the evidence on which the report was founded was most trumpery and insufficient, and we trust that our readers are convinced, that the only effective operation of the proposed measure would be to injure the best interests of the country. Commissioners of course are to be appointed, but where men competent for the duty are to be found, none but the concoctors of the bill can devine, for no practical man can. Qualified surveyors are still less to be expected, and raw theorists or ignorant empirics seem to be the classes from which these inquisitorial functionaries are to be supplied. To them are to be confided the most extraordinary powers, not only the mere privileges of meddling, but judicial authority over their victims. Even district surveyors are to have all the extra legal powers of a parliamentary committee, to call for papers and for documents, and to examine persons on oath, to prosecute for penalties, and to receive half those penalties for their own share. This is the plan to which all principles of justice, of truth, and of experience are to be sacrificed, and by which the talents and intellects of our ablest men are to be subjected, and manufacturers, some of whom have not less than a hundred thousand pounds invested in their business, are to be hampered and destroyed.

SURVEYING POLES.

Sir,—Allow me through the medium of your interesting Journal, to suggest to practical Surveyors a very useful, although seemingly trivial addition to the ordinary Surveying Poles, as a substitute for the piece of paper commonly used to render the pole distinguishable from a long distance when driving a line over land.

Front view. Side view. Back view.



It consists of a disc of tin about six inches in diameter, which for convenience in carrying may be joined across the middle as shown in the accompanying sketch; its open position being secured by a little bar A to be turned into the latch B. An iron ring or socket C is screwed on the top of the pole and receives the disc in a slit while the screw D secures it. It is almost needless to remark that the disc should be painted white on both sides.

Yours obediently,

G. P. DEMPSEY.

11, Craven-street. Charing Cross,
March 19, 1840.

OF THE OBLIQUE OR SKEWED ARCH.

While the system of communication from one part of the country to another continued to be transmitted through the medium of turnpike roads alone, the instances were few and far between in which the erection of an *oblique or skewed arch* became necessary. Indeed, unless in very confined and precipitous situations, we do not recollect a single case, where a structure of this kind has been resorted to for the purpose of carrying a road over a river or streamlet: nor was it requisite that it should, for in laying down the original plan of a road, the surveyor would generally possess the power of directing it, so as to intersect a river at right angles to its banks, and thus the necessity of carrying a bridge obliquely across the stream would be altogether avoided.

On the introduction of canals however, the circumstances were very materially altered, for it seldom happened that the direction of a road already constructed, was permitted to be changed for the purpose of accommodating it to the line of a projected canal, so as to traverse it perpendicularly; and in many cases it would be found inconvenient if not totally impracticable, to guide the canal across a road at right angles to its direction: hence the necessity of having recourse to the *skewed arch*, and accordingly, on the various canals that intersect the country, erections of this sort are very numerous, and the methods by which some of them have been constructed are exceedingly ingenious.

But it is in the construction of railroads that the *skewed arch* meets with its most important application, for in almost every instance where one line is intersected by another, the intersection takes place with a lesser or greater degree of obliquity, and several viaducts of considerable length are wholly supported by a connected range of oblique arcuation. This being the case, it is an object of the greatest importance that the correct principles of construction should be rightly understood, and it is for the purpose of establishing those principles and rendering their application easy, that the present investigation has been instituted.

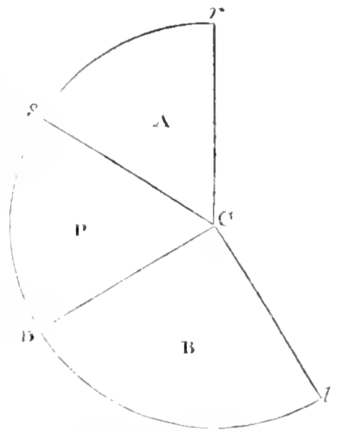
There are few architectural subjects that have excited a higher degree of interest than the present, and there is none that has given rise to a greater number of curious, abstruse and elegant theories, or been the cause of more violent and protracted controversies. One party contending that the just principle of construction, is to place the several courses of which the arch is composed in a direction parallel to the abutments, the direction of the coursing joints being regulated by the nature of the curve on which the arch is built. A second party maintains, that the several courses should be placed perpendicular to the face of the arch as far as the obliquity on both sides of it, and that the middle portion which stands upon the square, should have the courses laid parallel to the imposts or abutments. A third class of disputants insists upon laying the several courses perpendicular to the face of the arch throughout its whole extent, and trending them to the abutments in an angle dependent on the given obliquity; while a fourth class proposes to direct the courses in such a manner as to traverse the arch spirally like the threads of screw.

The subject itself is worthy of a mechanical investigation, and since we have been induced to direct our attention to it, we shall endeavour to the utmost of our power to set the question at rest, and point out the true principles of construction upon which depends the maximum of stability and strength.

In taking a minute and comprehensive view of the subject to which our present enquiries are directed, it will be proper for the sake of system, to consider the various theories above specified in the same order as we have described them. This in the first place will lead us to the contemplation of that variety where the courses are laid in a direction parallel to the imposts, and in which, (supposing the arch to be a semicircle,) the planes of the coursing joints on being produced to intersect the plan or base of the arch, are everywhere constrained to terminate in the axis or straight line, which passing through the centre of the semicircle divides the plan into two equal and similar portions.

The principle upon which the mechanical delineation of this particular form is founded, is exceedingly curious and interesting, referring as it does to the developement of the several parts of a right angled triangular pyramid upon a plane surface. This circumstance introduces a species of calculation that is not generally understood by practical architects, since it claims as its basis the doctrine of Spherical Trigonometry, a subject to which the attention of practical men is very seldom directed, although its applications are both numerous and important, and its principles remarkable for their elegance and simplicity. The objects of calculation are, the angles at the vertex of the pyramid comprehended between its edges, and the angles which measure the mutual inclinations of its bounding planes. Now, in order to assimilate the necessary operations to the determination of the levels or moulds by which the several voussoirs or arch stones are framed, we have only to consider the nature of the figure arising from the mutual intersections of the planes to which the moulds are severally applied.

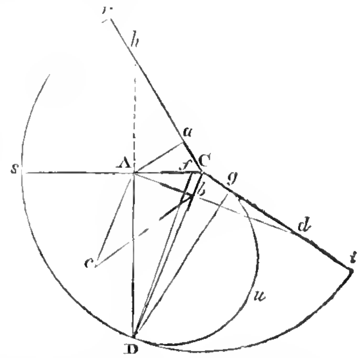
If the face or elevation of the arch, and the planes of the coursing joints or beds of the several voussoirs, be produced to intersect each other in the plan or base on which the arch is raised, they will, in connexion with the said plan, manifestly constitute a series of triangular pyramids having their vertices in the centre of the semicircle, and if the face of the arch be perpendicular to the plan, the pyramids will be all right angled: that is, two of the bounding planes in each, namely, the face and plan of the arch will intersect one another in an angle of ninety degrees.



Let the planes of the beds or coursing joints be produced externally, and conceive a circular arc to be described in each of the bounding planes, and having the vertex of the pyramid as a centre: then, the figures thus constituted will respectively resemble that which is exhibited in the margin, and upon the developement of which the construction of the arch depends.

A, part of the arch. P, part of the plan. B, part of bed prolonged.

If the middle plane or plan s C D be supposed to be fixed, while the extreme planes r C s and D C t are elevated about the lines C s, C D, till the points r and t, as also the radii C r and C t coincide, the nature of the figure thus formed will become manifest, and the expansions of its several parts upon a plane surface, may be effected in the following manner.



With the chord of 60 degrees taken from a scale of any convenient magnitude at pleasure, and about C as a centre, describe the circular arc r s D t, upon which and from the same scale of chords, set off r s and s D, respectively equal to the measures of the angles at the vertices of the perpendicular planes r C s and s C D.

Draw the radii C r, C s and C D, and in the radius C r take any point a at pleasure, and erect the perpendicular a A meeting the radius C s in the point A. At the point A determined in this manner, erect the perpendicular A D meeting the radius C D in the point D. From A, and on the radius C s set off A f equal to A a and draw D f. Upon C D as a diameter, describe the semicircular C u D, in which lay off the chord C g equal to C a, and D g equal to D f and draw the radius C t.

The above operation developes the triangular pyramid as far as it relates to the construction of the arch in question; D C t being the bevel of the bed or coursing joint, and A f D the bevel between the coursing joint and face of the arch. But in order to exhibit the complete developement of the figure, it is necessary to determine the angle which measures the inclination of the planes s C D and D C t; that is, the angle contained between the plan of the arch and the bed of the voussoirs for any particular course. From A or any other point whatever in the radius C s, let fall the perpendicular A b, carrying it forward to meet C t in d; then is A b the base, and b d the hypothenuse of a right angled plane triangle, between which the required angle lies. At the point A in the straight line d A, erect the perpendicular A c, and make b c equal to b d; then is A b c the angle sought, which having been found, the developement of the pyramid is complete.

The nature and principles of the above construction will be readily perceived by reversing the process; that is, by recomposing the figure from its constituent planes and the angles which measure their inclinations: and for this purpose, let the two extreme planes r C s and D C t be turned about the radii C s and C D, while the middle plane s C D remains fixed; and at the same, let the triangular planes A f D

Q

and $A\,b\,c$ be respectively turned about the lines A D and A b. Then it is manifest, that when the points r and t are made to coincide, the radii C r and C t coincide also, and form one of the edges of the triangular pyramid, as may be seen by elevating the corresponding planes in the preceding diagram; and by this means the figure is recomposed in so far as respects its constituent planes. Another step of the composition is effected by bringing into coincidence the straight lines A a, A f, and D f, D g; and when $b\,c$ falls upon $b\,d$ the structure is complete, both as respects the bounding planes and the angles which measure their inclinations.

It now remains to calculate the several parts of the pyramid, on the supposition that the angles at the vertices of the planes r C s and s C D are given; and in order to this,

Let c = r C s, the angle at the vertex of the plane r C s, which corresponds with a portion of the face of the arch,

b = s C D, the angle at the vertex of the plane s C D, which corresponds with a portion of the plan or base, and is perpendicular to r C s,

a = D C t, the angle at the vertex of the plane D C t, which is a portion of the bed or coursing joint, and subtends the inclination of the planes r C s and s C D,

B = A f D, the angle that measures the inclination of the planes r C s and D C t,

and C = A $b\,c$, the angle that measures the inclination of the planes D C t and s C D.

This notation being agreed on, let C A be made the radius; then by the definitions of trigonometry, A a and C a are respectively the sine and cosine of the angle A C a, while A D is the tangent of the angle A C D. But by the construction, A f is equal to A a, and consequently A f is equal to the sine of the angle r C s; therefore, by the principles of plane trigonometry, we have

A f : A D : : rad. : tan. A f D; that is, sin. c : tan. b : : rad. : tan. B = tan b, cosec c.

Here we have determined the angle of inclination between the planes r C s and D C t, and a similar process will discover the angle A $b\,c$, or the inclination between the planes s C D and D C t. Thus, since C A is radius, A b is the sine of the angle s C D to that radius, and by construction, A c is equal to the tangent of the angle A C a, for A c is equal to A h, and A h is evidently the tangent of the angle A C a to radius C A; therefore, by plane trigonometry, we get

A b : A c : : rad. : tan. A $b\,c$; that is, sin. b : tan. c : : rad. : tan. C = tan. c, cosec. b.

We have next to determine the angle b C d in the plane D C t, and for this purpose it is only necessary to recollect, that C g is equal to the cosine of A C a, and C D equal to the secant of A C D; hence we have

C D : C g : : rad. : cos. D C g; that is, sec. b : cos. c : : rad. : cos. a = cos. b, cos. c.

And exactly in the same manner, if any other two of the parts be given the rest may be found, and the several results when calculated and reduced to their simplest form, are respectively as exhibited in the following table:

Table of formulæ for calculating the several parts of a right angled triangular pyramid standing on a spherical base.

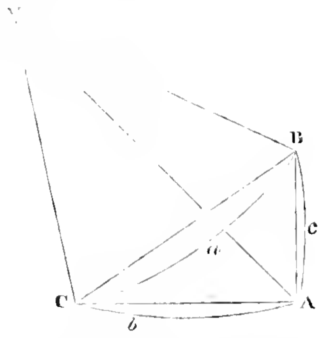
	Values of the angle B, subtended by the base or plane A V C.
1	sin. B = sin. b cosec. a.
2	sin. B = sec. c cos. C.
3	tan. B = sec. a cot. C.
4	tan. B = tan. b cosec. c.
5	cos. B = cot. a tan. c.
6	cos. B = cos. b sin. C.

	Values of the angle a, at the vertex of the hypothenusal plane B V C.
1	sin. a = sin. b cosec. B.
2	sin. a = sin. c cosec. C.
3	tan. a = tan. b sec. C.
4	tan. a = tan. c sec. B.
5	cos. a = cos. b cos. c.
6	cos. a = cot. B cot. C.

	Values of the angle c, at the vertex of the perpendicular plane A V B.
1	sin. c = sin. a sin. C.
2	sin. c = tan. b cot. B.
3	tan. c = tan. a cos. B.
4	tan. c = sin. b tan. C.
5	cos. c = cos. a sec. b.
6	cos. c = cos. C cosec. B.

	Values of the angle C, subtended by the perpendicular plane A V B.
1	sin. C = sin. c cosec. a.
2	sin. C = sec. b cos. B.
3	tan. C = sec. a cot. B.
4	tan. C = tan. c cosec. b.
5	cos. C = cot. a tan. b.
6	cos. C = cos. c sin. B.

	Values of the angle b, at the vertex of the plane or base A V C.
1	sin. b = sin. a sin. B.
2	sin. b = tan. c cot. C.
3	tan. b = tan. a cos. C.
4	tan. b = sin. c tan. B.
5	cos. b = cos. a sec. c.
6	cos. b = cos. B cosec. C.



The above table contains the simplest forms of the equations necessary for resolving the different cases and varieties of right angled spherical triangles, as they depend upon the triangular pyramid V B A C. It is designed to preclude the necessity of either learning by rote or investigating the various rules and proportions connected with this branch of the subject; for by simply referring to that compartment of the table which contains the values of the quantity sought, an expression will be found denoting the precise operation to be performed for the value of the required term. Thus for example. Suppose that in the right angled spherical triangle B A C, the base A C = b, and the perpendicular B A = c are given, and it is required to find;

1. The hypothenuse B C = a.

2. The angle A B C = B contained between the hypothenuse B C and perpendicular B A, or that which is subtended by the base A C.

To find the hypothenuse B C = a, refer to that compartment of the table that contains the values of the hypothenuse, and select that expression which exhibits a combination of the given quantities b and c This is readily perceived to be No. 5, the only case in which the two given terms form an equation with the one required; hence we get

$$\cos.\ a = \cos.\ b\ \cos.\ c.$$

And the numerical operation denoted by this expression, may, when converted into words, be read in the following manner:—

Multiply the natural cosine of the given base, by the natural cosine of the given perpendicular, and the product will give the natural cosine of the hypothenuse.

The multiplication of trigonometrical quantities is however a very laborious process, unless the contracted method of decimal multiplication is resorted to; and since very few of our practical mechanics have taken the trouble to familiarize themselves with the application of that method, the necessity of employing it may be entirely superseded by the use of logarithms. The rule will then be as follows:—

Add together the logarithmic cosines of the given parts, and the sum will be the logarithmic cosine of the part required.

Note.—The reader is supposed to have a previous knowledge of the trigonometrical definitions, logarithmic tables, and algebraic notation.

The general application of the table may be described in words at length in the following manner:—

Add together the logarithms of the two given quantities according to their names in the equation, and the sum will give the logarithm of the required quantity according to its name in the particular combination employed, observing always to abate 10 in the index of the resulting logarithm.

Again, to find the angle ABC = B, contained between the hypothenuse and perpendicular, we have only to refer to that compartment of the table containing the values of B, and to select the combination which involves the given quantities; in this case it is No. 4, from which we have

tan. B = tan. b cosec c;

an equation which is readily reduced by the general rule given above.

In reference to the arrangement of the table, it may be remarked that it forms a right angled triangle, the same as the figure under consideration, and the squares or compartments containing the values of the several parts, are placed in the same positions with respect to each other as the parts are whose values they contain. Thus, in the figure BAC, the hypothenuse a occurs between the angles B and C; so in the table, the square containing the values of the hypothenuse, is placed in a diagonal direction between the squares containing the values of the angles B and C.

In the figure the perpendicular c occurs between the angle B and the right angle at A; so in the table, the square containing the values of the perpendicular, occurs between the square containing the values of B, and the blank square for the right ang e where no value enters

Finally, in the figure, the base b falls between the angle C and the right angle at A: so in the table, the square containing the values of the base, is placed between the blank square for the right angle and the square containing the values of the angle C; an arrangement which is beautifully adapted for the purpose of a speedy reference.

The two equations that we have selected from the table, are those which apply to the determination of the bevels for the several voussoirs throughout the whole extent of the arch. The first determines the form of the beds, or the angle contained between the joints in the face of the arch, and the corresponding joints along the soffit; and the second determines the angles contained between the face of the arch and the beds of the several courses. The application of which we now proceed to illustrate by means of an example.

Suppose a semicircular arch of 30 feet span, and consisting of 34 courses from impost to impost, to be built upon an obliquity of 68 degrees with the abutments, what are the several bevels required for the construction of the arch stones or voussoirs in each of the courses?

Since the arch is a semicircle of 30 feet span and consisting of 34 courses, that is, 17 courses between the crown of the arch and each of the imposts; it follows, that each voussoir occupies 5° 17′ 38″ $\frac{14}{17}$ of the circumference, having a soffit or intrados of 2·795 feet very nearly; consequently, the successive portions of the circumference, estimated from the impost to each of the beds or coursing joints as far as the crown or middle of the keystone, are respectively as in the following tablet.

Courses.	°	′	″	Courses.	°	′	″
1st	5	17	38$\frac{14}{17}$	9th	47	38	49$\frac{7}{17}$
2nd	10	35	17$\frac{11}{17}$	10th	52	56	28$\frac{4}{17}$

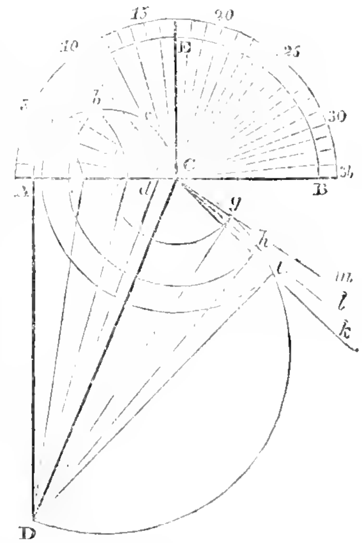
The 17th course, or course at the crown of the arch, corresponding an angle of 90 degrees as it ought to do, when the keystone is in two parts, as we have assumed it to be in the present instance, for the express purpose of showing the influence of the obliquity upon the bevels in that course. From these angles therefore, with the constant obliquity of 68 degrees, we derive the following construction for the case in question.



Let A E B in the subjoined drawing, represent the elevation of the given semicircular arch, of which C is the centre, and A B the span or diameter. At the centre C, make the angle A C D equal to 68 degrees the given obliquity, so that C D shall coincide with the axis of the arch, and point out the direction of the abutments to which it is parallel. From the beginning of the arch at A, set off successively the values of several arcs in the tables corresponding to the respective number of courses estimated from the impost at A to the crown of the arch at E, and from thence in a retrograde order to the other impost at B.

Upon A C the radius of the arch describe the semicircle A a b c C, intersecting the radii C 4, C 8 and C 12 respectively in the points a, b and c, and at A erect the perpendicular A D meeting C D the axis of the arch in D.

About A as a centre, with the distances A a, A b and A c, describe the arcs a f, b e and c d, meeting the radius A C in the points f, e and d respectively, and draw the straight lines D f, D e and D d: then are the angles A f D, A e D and A d D or their supplements, the angles contained between the face of the arch and the planes of the coursing joints at the 4th, 8th and 12th courses, or at the corresponding divisions on the opposite side of the arch. These are the angles corresponding to the letter B in the figure of the table of formulæ, and if they are respectively taken in the compasses and applied to a scale of chords, they will be found to indicate 81° 41′ 46″, 74° 46′ 25″ and 70° 6′ 59″.

Upon the straight line C D as a diameter describe the semicircle C g h i D, in which lay off the distances C i, C h and C g respectively equal to C a, C b and C c; then will the angles D C k, D C l and D C m or their supplements, be the bevels of the beds or coursing joints at the 4th, 8th and 12th divisions, or at the corresponding divisions on the opposite side of the arch; the bevels in the two cases being constantly the supplements of each other.

The angles just determined from the last step of the construction, are those which are measured by the arc a in the tabular figure, and if they are severally taken in the compasses and applied to a scale of chords, they will be found to indicate 69° 33′ 17″, 73° 55′ 12″ and 80° 23′ 16″ respectively, for the bevels in the beds or coursing joints corresponding to the 4th, 8th and 12th divisions of the arch.

The values of B, or the bevels between the face of the arch and the planes of the coursing joints at the specified divisions of the arch, are also determined from the 4th formula in that compartment of the table containing the values of B. Thus we have tan. B = tan. b cosec c, and taking the parts of the circumference at the respective divisions, we get as follows:

	°	′	″			
4th division	21	10	35 $\frac{5}{17}$	- - -	log. cosec.	0·442204
Value of b =	68	0	0	constant obliquity	log. tan.	0·393590
Value of B =	81	41	46	- - - -	log. tan.	0·835794
8th division	42	21	10 $\frac{10}{17}$	- - -	log. cosec.	0·171538
Value of b =	68	0	0	constant obliquity	log. tan.	0.393590
Value of B =	74	46	25	- - - -	log. tan.	0.565128
12th division	63	31	45 $\frac{}{17}$	- - -	log. cosec.	0·048098
Value of b =	68	0	0	constant obliquity	log. tan.	0·393590
Value of B =	70	6	59	- - - -	log. tan.	0·441688

For the values of a, or the bevels in the planes of the beds or coursing joints, the formula is cos. a = cos. b cos. c; and the operation is as follows:—

	°	′	″				
4th division	21	10	35 $\frac{1}{17}$		-	-	log. cos. 9·969637
Constant obliquity	68	0	0	-	-	-	log. cos. 9·573575
Value of a =	69	33	17	-	-	-	log. cos. 9·543212
8th division	42	21	10 $\frac{10}{17}$		-	-	log. cos. 9·868651
Constant obliquity	68	0	0	-	-	-	log. cos. 9·573575
Value of a =	73	55	42	-	-	-	log. cos. 9.442226
12th division	63	31	45 $\frac{15}{17}$		-	-	log. cos. 9·649080
Constant obliquity	68	0	0	-	-	-	log. cos. 9·573575
Value of a =	80	23	16	-	-	-	log. cos. 9·222655

We have limited the preceding construction and calculation to three courses only; this we have done for the purpose of saving room and preventing confusion in the figure; but from what has been effected, the reader will readily trace the method of procedure in any other case.

PROPOSED EMPLOYMENT OF VIBRATING CYLINDERS FOR THE LARGEST CLASS OF MARINE ENGINES.

The compact form of the vibrating cylinder engine, its light weight, and the small section of the vessel which it occupies, together with the advantage of having the strain from the thrust or pull of the piston entirely within its own framing, and not partially transferred to the kelsons of the vessel, as is the case in the beam engine: seem to point it out as peculiarly applicable to steam navigation, and especially to those gigantic efforts which are now making to extend our intercourse with distant countries, where the advantage of having large power in small space cannot be too highly appreciated, as the various efforts of the most celebrated makers to effect that object sufficiently testify.

Various reasons however have been assigned why this form of engine should not succeed on a large scale, and these I shall endeavour to notice and refute.

1st. The great weight of the valve easing and slide on one side has been objected to as destroying the equilibrium of the cylinder, and wearing the cylinder and stuffing box unequally.

2d. The difficulty of casting the cylinder and hollow gudgeons sound, and the impossibility of repairing them in case of a failure.

3d. The disadvantage of passing the steam through the gudgeons at all, owing to the heat occasioning an unnecessary friction.

4th. The loss of power in communicating a vibrating motion to such a large body as the cylinder. And lastly, the difficulty of packing.

Now if the above named objections can be got over, which I think there will be little difficulty in doing, we shall then have an engine free from all the disadvantages of increased friction and short connecting rods; more compact in its form, and less exposed above the water line than any yet before the public, and consequently more eligible for the purpose of commerce or war.

To get rid then of the first objection, I propose to dispense with the slide altogether, and to substitute in its place four double-beat valves as used in the Cornish engines: one top and bottom of the cylinder on either side, two being steam and two exhaustion valves.

I conceive there are many advantages to be derived from this form and arrangement of the valves. Thus, the steam valves would also serve as expansion valves, as being independent of the others there would be no difficulty in shutting them at any point of the up or down stroke of the piston, affording us the opportunity of so adjusting them, as to avail ourselves to any desired extent of the principle of expansion. The exhaustion valves would have the same facility of adjustment, so that we should be enabled to open and shut the passage to the condenser at the point which would ensure the most effective working of the engine; such valves also afford great facility of repair; with the additional advantage of one man being able to handle both engines, although the cylinders were ten feet diameter, as such valves being almost balanced, lift or open, with the slightest exertion.

2d. I would cast the gudgeons on a separate circular frame, just large enough to encircle the cylinder and to which the cylinder should be securely bolted by a strong projecting flange; this would occupy a very little additional breadth, and would entirely get over that difficulty.

3rd. I do not know that passing the steam through the gudgeons is a serious evil, but at all events it can be very easily obviated.

Let the joint and stuff box be placed on the end of the gudgeon as usual, so as to be concentric and firmly secured, and let a flat pipe be carried up till sufficiently clear of the plummer-block cover, and then bent over and secured to the body of the cylinder, when it can be easily connected with either set of valves; by this arrangement the steam does not pass through the gudgeons at all.

4th. This I have often heard urged as an insuperable obstacle to the successful application of this form of engine, but when we consider that the working beams, crossheads, &c., in almost every case exceed the weight of the cylinder—further that the beams, crossheads, &c., must in all cases move through twice the space, and in many cases through three times the space of the vibrating cylinder for the same length of stroke, it will then appear plainly that this objection has no foundation, the loss of power from the same cause being evidently less than in a common engine.

The last objection, viz., the difficulty of packing, seems scarcely worth notice, as it has been perfectly overcome in numerous boats now running.

The stuffing box ought to be considerably deeper than in common engines, and the piston rod somewhat stronger.

The air pump, feed and bilge pumps can be easily worked from the intermediate shaft, as frequently done. But I should greatly prefer having a separate steam cylinder to work all those pumps, working in connection with and at pleasure, detachable from the main cylinders, this would get rid of the crank or eccentric on the intermediate shaft, which is to a certain degree objectionable. It might be so arranged as to be quite out of the reach of shot, and would not occupy any additional space on the floor of the vessel beyond that occupied by the engine framing; the following striking advantages wou'd accrue from this arrangement: we should be enabled to keep up the steam and preserve a vacuum for any length of time, so as to start at a moment's notice; and secondly, what I consider of far greater importance, the turn of a cock, or opening of a valve might convert the air pump into an immense bilge pump, with an available power to work it, and sufficient to keep the vessel clear under almost any circumstances. The additional security to the shipowners, and safety to the passengers, which this would ensure in case of the vessel taking ground, or in other circumstances when it might be inconvenient or impossible to work the engines, cannot be too highly estimated; and I have no doubt there are many naval men who at one time or other would gladly have availed themselves of such a power. But if this arrangement be considered too decided an innovation, they can be worked in the usual manner.

In conclusion, I see no difficulty in the manufacture, nor any reason to apprehend a failure; and as such an engine would occupy not more than half the space of a common beam engine, would weigh very considerably less, and would, as before mentioned, be free from all the disadvantages of increased friction or short connecting rods, with the advantage of being less exposed above the water line: and lastly, could be made for quite as little, if not less expense; it is well worthy of the attention of the heads of our naval establishment, and of steam boat proprietors in general, and if there be any thing against it which I have overlooked, perhaps some of your numerous correspondents could point out where the fault lies.

A. S.

Pimlico, March 17, 1840.

TABLE OF ARCHITECTS WHO HAVE DIED IN THE 18TH AND 19TH CENTURIES.

By W. H. Leeds.

Imperfect as the following Table is, *in tenui labor* might be its motto, since the drawing it up has cost far more pains and research than it ought to have done, or would have done, had not architectural biography been notoriously slighted. Relative to Italian architects and a few others of preceding periods, information may be met with in general biographical works, because the materials for such articles are abundantly supplied by Vasari, Baldinucci, and other writers of that class; but, with here and there an exception, such biography becomes more and more meagre, precisely when it might be expected to be more copious and satisfactory, namely, as we approach our own times. Not having the original work by Milizia to refer to, I do not precisely know which are the "Additional Lives," inserted by his English translator, but it certainly does not say much for either the diligence or judgment shown by her, when we find such names as those of Langhans, Antoine, and Ledoux omitted, while such a person as Joel Johnson, is deemed worthy of notice. The appendix to Quatremere de Quiney's "Vies des Architectes," gives a few notices of architects who lived in the two last centuries, yet in only one or two instances is there a date of any kind, which is certainly a more original than laudable mode of treating biography and history. Even Nagler's work, which professes to give notices of both living and deceased artists of every class, and which, when completed, will contain several thousand articles, makes no mention of Ginseppe Marvuglia, the architect of the beautiful Oratorio dell'Olivella, at Palermo, (given in Zanth and Hittorff's Archit. Mod. de la Sicile), nor have I been able to discover elsewhere any further mention of him, consequently, have no clue to even an approximating date for the time of his death. Though his journey was professedly an architectural one, Woods does not even mention the building at all; and indeed, as far as recent Italian architecture is concerned, the art might be supposed to be now altogether extinct in that country, judging from the dogged silence of all our later travellers and tourists in regard to it, for though some of them bore us with common Guide-book remarks on Palladio, scarcely one of them appears to have been aware of the existence of a Marvuglia, a Calderari, or a Cagnola, or of such living nobodies as Buonsignore, Bianchi, Canonica, Canina, and—not to go through the whole alphabet, numerous others, whose names ought now to be tolerably familiar to us here at home—at least to those engaged in architectural studies, and caring to be *au courant du jour* in the history of the art. What is still more extraordinary is, that where buildings are noticed, or even fully described as in Forster's Bauzeitung, there is frequently not either date or architect's name to assist the future historian.

As far as it goes, the present table affords a chronological synopsis that may be useful for reference, and for occasionally refreshing the memory. A similar one of buildings erected within the same period, might be drawn up as an accompaniment to, or skeleton of, architectural history during the last and present century; but it would be greatly more extensive, and in fact, there ought to be a separate table of the kind for each country. In the meanwhile, I am content to offer this specimen, and should any correspondent be able to suggest any additions, or fix any dates here left in uncertainty, I should feel obliged by his doing so.

CHRONOLOGICAL TABLE OF ARCHITECTS WHO DIED IN THE 18TH AND 19TH CENTURIES.

WHERE the precise date of an architect's death could not be ascertained, it is indicated by *ab.* (about). An asterisk * is prefixed to the names of those who have distinguished themselves, not as architects, but as writers on architecture, &c. The names of places in Italics denote that the architect was chiefly employed there.

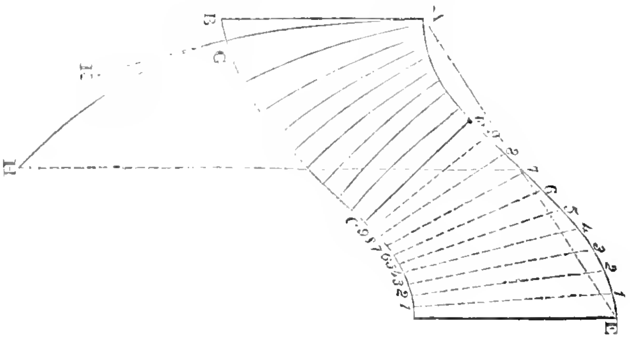
SKEW ARCHES.

SIR,—I am surprised that among the many correspondents who address you, there are so few of them either theoretical or practical, who touch upon the subject of skew arches, a subject which presents so wide a field of observation and remark.

Among the very few works which we possess on this point, Mr. Buck's seems to hold the highest place, although even in it there seems to me several things which would be the better for alteration or amendment. Although he is particular in giving the mathematical formula for calculating the necessary angles and lines, yet he assumes some things, as granted, which lie at the very foundation of his principles: for example, he observes that the lines of the courses of the intrados should be made perpendicular to a line drawn between the extremities of the developement of the face of the arch, without ever giving any reason for it, or making any remark on the subject, farther than that it should be so. Now it strikes me that a considerable alteration may be made in this for the better. Let A B C D E F (in the figure annexed) be the developement of a semicircular arch, then



there is a curve A G H, such that a tangent drawn from any point in this curve is perpendicular to the face of the arch at the said point, as, the tangent G K, drawn from the point G is perpendicular to the developement of the face of the arch B, G C, at the said point G. Now if the courses were drawn similarly to this as shown in that part of the figure A, B, C, F, then the arch (according to Mr. Buck, in the beginning of his seventh chapter) would be perfectly secure. Unfortunately however, the difficulty of execution would be so great, if it is not an impossibility, that this could never be applied vigorously to practice, and the only way left is to make the best practicable approximation to this curve. There are two methods, either of which appear to me to be better than that of Mr. Buck's, although the first has a considerable drawback, because the beauty of the arch is very much destroyed on account of the unequal divisions of the courses. The first method is after having drawn a line as F C perpendicular to the face of the arch at the centre, to divide the segments F E, and C D into an equal convenient number of parts, and to draw the courses as shown by dotted lines from the one face to the other through the respective points 1, 1—2, 2—3, 3, &c. This, although a little more expensive than the common method, appears to me more desirable on account of the additional strength which it possesses. I may mention that I was shown a model built upon this principle, which when subjected to a pressure on the crown, forced the abutments asunder exactly in the line of the face of the arch, thus giving the best proof of the correctness of the principle. The second method which I would recommend is simply instead of drawing the line of the intradosal courses perpendicular to the straight line A E, to draw it nearly averaging the curve A G H, the tangent of the angle which such a line would form with the abutments approximates to $\frac{\cot\theta}{2}$. θ being the angle of the acute corner of the abutments. The advantages to be derived from this are, first that this angle being less than that commonly employed, there will be less tendency to slip, and secondly, that being more nearly perpendicular to the face of the arch, there is consequently more stability.

I am astonished at the serious errors into which Mr. Buck has fallen in his last chapter, which is devoted to *further investigations*, but which had better have been omitted altogether. In attempting to determine at what attitude above the level of the axis of the cylinder the thrust of the arch will be perpendicular to the bed of the voussoir, he gives a formula which produces the strange result that the smaller the archstone, the lower will be the said attitude, that is to say, the more secure will be the arch, and also that it will be able to be built at a more acute angle. Another still more strange phenomenon, the result of this formula, is that the greater the skew of the bridge the less of the arch will have to be supported by iron dowels and bolts; thus an arch built at an angle of 25° will require no assistance from dowels, an arch built at an angle of 55° will require to be secured by dowels to a height of 25° above the springing, and lastly, an arch of 90° or square to the abutments, will have to be secured to a height of 40° above the springing. The whole of these errors arise from having given the expression $\frac{\text{cosec.}\ \theta.\ \cos\tau}{\frac{1}{2}\pi}$ (nearly at the bottom of page 37), instead of $\frac{\cot\theta.\ \cos\tau}{\frac{1}{2}\pi} \div$ cosine $(\theta+\phi)$ where ϕ is such an angle that its tangent is $= \frac{\cot\theta.\ \sin\tau.}{\frac{1}{2}\pi}$ This must be evident to any one who considers that the courses alter their angle with regard to the face of the arch, which Mr. Buck has not taken into consideration.

As it may be of some use to settle this problem, I would submit the following solution, observing that the letters and charaters refer to the same as in Mr. Buck's treatise.

1st. In finding a term for C O, I would reject the thickness of the cylinder, and consider the point O as that to which the tangents of the small curves which show in the face of the arch, tend: this is more correct because the joints of the voussoirs being segments of curves, there can be no point on the face of the arch at which a ball would roll down the bed into a line exactly parallel to the face; this may be considered too minute for observation, but besides being more correct it will simplify the question much.

Then upon this ground C O $= \frac{\cot^2\theta}{\frac{1}{2}}$, and taking Mr. Buck's own figures at the bottom of page 37. I E K $= \frac{\cot^2\theta + \nu.\ \sin\tau}{\nu.\ \cos\tau.\ \text{cosec}\ \theta}$.

2d. In finding the tangent of the internal angle, Mr. Buck states correctly "that the tangent of the angle, which the tangent of the intradosal spiral makes with the horizon diminishes as cos. τ," but he has omitted to mention that the angle θ, which the course makes with the face at the springing, increases as a certain function of sin. τ becoming $(\theta+\phi)$, where ϕ is such an angle that it has for a tangent $\frac{\cot.\ \theta.\ \sin.\ \tau}{\frac{1}{2}\pi}$; this then would make the tangent of the internal angle at the point sought $\frac{\cot\theta.\ \cos\tau}{\frac{1}{2}\pi.\cos(\theta+\phi)}$, then equating these values of the external and internal angles, we have

$$\frac{\cot\theta.\ \cos\tau}{\frac{1}{2}\pi.\ \cos(\theta+\phi)} = \frac{\frac{\cot^2\theta}{\frac{1}{2}\pi} + \nu.\ \sin\tau.}{\nu.\ \cos\tau.\ \text{cosec}\ \theta}$$

but rejecting ν in the second side of the equation, because by hypothesis it is unity, and multiplying both sides by $\frac{1}{2}\pi$, cos. τ, cosec θ, we have $\frac{\cot\theta.\ \cos^2\tau}{\sin\theta.\ \cos(\theta+\phi)} = \cot^2\theta + \frac{1}{2}\pi.\ \sin\tau.$

After this the solution must be completed by a series of approximations until a true value of τ can be found. If the thickness of the archstones is wished to be considered, then by making the second side of this last equation $\cot^2\theta.\ \frac{\nu+e}{\nu} + \frac{1}{2}\pi.\sin\tau.$ it will give the required result, thus,

$$\tau \text{ when C O} = \frac{\cot^2\theta}{\frac{1}{2}\pi}\ \nu, \text{ or } \tau \text{ when C O} = \frac{\cot^2\theta}{\frac{1}{2}\pi}.\ \nu + e,$$

		° ′				°
When θ is 60	then	40 56	-	-	-	40
45	-	42 46	-	-	-	40
30	-	50 10	-	-	-	43

The numbers in the last column are only approximations, but it may be taken that in all arches of a moderate skew, the point τ is about 40° above the level of the axis of the cylinder.

I have merely thrown out these observations for the purpose of directing attention to this particular kind of arch, which is now come into such common use, and about which we have so little information, and that little of a very loose kind with regard to the theory of the arch, but I think that Mr. Buck is entitled to the thanks of the profession for the clearness and accuracy with which he has explained and illustrated the greater portion of the subject practically considered.

I remain, Sir, your's respectfully,

B. H. B.

Edinburgh, March, 1840.

AMERICAN STEAM BOATS.

The following comparison of the power of the engines employed in the steam boats navigating the rivers of North America and those running here on the Thames may not be uninteresting to many of our readers, particularly those who are engaged in steam navigation.

We have taken as the basis of our calculations the following particulars of the "Rochester," a steam boat plying on the river Hudson, between New York and Albany, which have been furnished by Mr. David Stevenson in his "Sketch of the Civil Engineering of North America."

The Rochester is 209 feet 10 inches in length, and 24 feet beam, the depth of her hold is 8 feet 6 inches, and she draws, with an average number of passengers, 4 feet of water. The diameter of the paddle wheels is 24 feet, and the length of the floats, which are 24 in number on each wheel, is 10 feet, and their dip, under the above circumstance, 2 feet 6 inches. The vessel is propelled by one engine, having a cylinder 43 inches in diameter, with a 10 feet stroke. The steam, which is generated under a high pressure, is cut off at half stroke, and condensed.

Under ordinary circumstances the engine is worked by steam of from 25 to 30 lbs. pressure, and in this case the piston makes about 25 double strokes per minute; but when the Rochester is pitched against another vessel, and at her full speed, the steam is often carried as high as 45 lbs. on the square inch in the boiler, and the piston then makes 27 double strokes, or in other words, moves through a space of 540 feet per minute, or 6·13 miles an hour. In this case the circumference of the paddle wheels moves at the rate of 23·13 miles an hour.

It was under these circumstances that Mr. Stevenson made a passage in this vessel, during which he informs us she attained a speed of 16·55 miles an hour, her piston then making 27 double strokes per minute, and the tide being just on the turn; by which we judge the pressure of the steam in the boiler to have been 45 lbs. on the square inch. Mr. Stevenson remarks that "at that time the vessel could not be far from having attained the maximum speed at which her engines are capable of propelling her through the water." What the precise signification of this observation may be we do not exactly comprehend: the only way in which we can account for it is either that hard firing was carried nearly to the greatest extent possible in the furnaces, or that 45 lbs. on the square inch was not far from the highest pressure which the boiler was capable of sustaining without damage.

Allowing that at this great speed the steam is wire-drawn to such a degree as to lose 4·71 lbs. of its pressure (which is a much greater loss than is probably experienced in reality), we will assume the initial pressure of the steam in the cylinder to have been (including the pressure of the atmosphere) 55 lbs. on the square inch. The relative volume of steam of this pressure is 507·3, and as it is cut off at half stroke, its mean pressure through the stroke, reckoning the waste space at the end of the cylinder at $\frac{1}{20}$ of the contents of the cylinder, was 46·47 lbs. From this must be deducted the pressure in the condenser, which Mr. Stevenson estimates at 5 lbs. per square inch. This leaves a mean effective pressure of 41·47 lbs. per square inch, which multiplied by the area of the piston, which is 1452·2 square inches, gives 60222·73 lbs. for the total effective pressure on the surface of the piston, and multiplying this by its velocity 540, and dividing by 33000, we find the gross power to be 985·463 horse power. If we considered the pressure in the condenser as a part of the load of the engine, which would be the fairest way to show the comparative merits of different engines, since it is a defect when the pressure in the condenser is considerable, we should find the gross power of the Rochester's engines to be 1104·3 horse power.

Supposing the above data to be correct, the quantity of water boiled off to supply the engine must have been 5·9041 cubic feet per minute, or 354·246 cubic feet per hour.

Considering the Rochester's midship section as a rectangle, its area cannot exceed 96 square feet, and the power employed in propelling her at any given speed must bear some proportion to that area, depending on the form of her body. The power is also admitted to vary as the cube of the velocity; therefore the total power employed in propelling a certain vessel at a given speed may be represented by the expression

$$K A V^3,$$

in which K is a coefficient depending on the form of the vessel, A the area of her immersed midship section, and V her velocity.

The Gravesend steam boat "Ruby," belonging to the Diamond Company, is 155 feet in length, and her beam 19 feet. Her draught of water with 300 passengers on board was 4 feet 4 inches forward, and 4 feet 8 inches aft, mean 4 feet 6 inches, and the area of her midship section immersed 65·6 square feet. The diameter of her paddle wheels is 17 feet 2 inches, the number of floats on each wheel 1[illegible], their length 9 feet, depth 18 inches, and their dip under the above circumstances 20 inches.

The vessel is propelled by a pair of engines of 50 horse power each. The diameter of the cylinders is 40 inches, the length of stroke 3 feet 6 inches, pressure of steam in the boilers 3½ lbs. above the atmosphere, vacuum in the condensers 28¼ inches, number of revolutions per minute 31½, and speed of the vessel 13·5 miles per hour.

The area of the two pistons taken together is 2513·28 square inches, and the effective pressure of the steam on each square inch of the pistons is 3·5 + 13·852 lbs. = 17·352 lbs. which multiplied by the area of the pistons gives the total effective pressure = 43610·43 lbs., and multiplying this by the velocity of the pistons, which is 220·5 feet, and dividing by 33000, we find the gross power = 291·4 horse power. Or, considering the pressure in the condenser as a part of the load, as we did for the Rochester, the pressure on each square inch of the pistons being 3·5 + 14·74 = 18·24 lbs., we should find the gross power = 305·81 horse power. Of this gross power, which we will call P, a certain portion is employed in overcoming the friction of the engine and the resistance of the steam in the condenser, owing to the vacuum not being perfect; and we may assume this portion, in engines of the same construction and working on the same system, to bear a constant proportion to the gross power P. The remainder, which is employed solely in propelling the vessel, may therefore be represented by the expression k P, in which k is a constant coefficient.

We have shown above that this quantity may also be represented by

$$K' A' V'^3,$$

K′ being the coefficient of resistance of the Ruby, A′ her immersed midship section, and V′ her velocity. We must therefore have

$$k P = K' A' V'^3.$$

If P′ be the gross power required to propel a vessel of the same form as the Ruby, but whose midship section immersed is equal to that of the Rochester, or A, at the velocity V, which is that of the Rochester, we shall have

$$k P' = k P \frac{A V^3}{A' V'^3},$$

or

$$P' = P \frac{A V^3}{A' V'^3}$$

Substituting the values of all the known quantities, we obtain

$$P' = 305{\cdot}81 \frac{96 \times 16{\cdot}55^3}{65{\cdot}6 \times 13{\cdot}5^3} = 824{\cdot}54,$$

which is less than three quarters of the gross power of the Rochester's engine.

The effective power of the Ruby's engines, that is, the power applied to the paddle wheels, calculated from the resistance to the floats by Mr. Mornay's method given in Tredgold's Treatise on the steam engine, page 132 of the Appendix, but with double the coefficient, (Mr. Mornay having found since the publication of the above mentioned work, that the resistance to a body moving through a fluid should be double what the generally received theory makes it), is found to be equal to 267·86 horse power; but if we calculate their effective power by M. de Pambour's rule, which is to deduct from the effective pressure on the piston first 1 lb. per square inch for the friction without load, and then one-eighth of the remainder for the friction due to the load, we find only 240·285. The two methods would, however, give precisely the same result if the pressure in the boiler were 5·38 lbs. above the atmosphere; but it is probable there are some inaccuracies in the data of both calculations, and the discrepancy is not very great, the ratio of the two numbers obtained being very nearly 9 : 10. However, to give the Americans the advantage of every doubt, we will assume the pressure in the boilers to have been 5 lbs. on the square inch. (It would be unreasonable to allow more). In this case the gross power would be 331 horse power, and the disponible power by M. de Pambour's method, 262·315 horse power. The ratio of the latter to the gross power 331, or k, is thus equal to ·79249.

The gross power being assumed to be 331, instead of 305·81 horse power, makes P′, the gross power required to propel the larger vessel of the same form as the Ruby at the rate of 16·55 miles an hour 892·46 horse power, which multiplied by k, gives 707·27 for the disponible power required to be applied to the paddle wheels.

The amount of power absorbed by friction and other losses in the engines is thus, on the principle of the Ruby's engines 185·19 h. p., on that of the Rochester's 397·03 h. p.

So that the London engineers are not only capable of constructing engines which would propel vessels at the rate of 16·55 miles an hour (which has only been claimed for the Americans in one solitary instance), but they can obtain that result with less than nine-elevenths of the power employed by their transatlantic brethren.

It is however to be observed that the quantity of water boiled off, and consequently the expenditure of fuel would be greater in the English engines of 892·46 horse power in the American engines of 1104·3, owing to the steam in the latter being expanded in the cylinder; but it is evident that, by adopting the principle of expansion in the English engines, the saving of fuel would be in proportion to the saving of steam, and might be carried even much farther than in the engine of the Rochester.

ABSORBENT ARTESIAN WELLS.

By Hyde Clarke, Esq., C.E., F.L.S.

The plan of artesian wells for the supply of water, we have mainly derived from our neighbours the French, and it is one which has been frequently canvassed in your Journal. I have now to call the attention of your readers to another application of boring, which in the present advanced state of geological knowledge and mechanical science may perhaps be productive of some advantage here. It is that of absorbent artesian wells, or cesspools, a system successful on a small scale, but which I am not aware has been carried to the same extent as in France.

The following account of absorbent artesian wells at Paris is principally derived from the report hereafter referred to made to the Prefect of Police by M. Parent Duchatelet, the well known writer on hygienic police. The reasoning will apply equally to London, as the London basin is much the same as that of Paris, with the omission of the tertiary building stones.

The city of Paris, for the purpose of suppressing the Laystall at Montfaucon, has within the last few years established a new one in the forest of Bandy. Although, this latter in 1833, received only a quarter of the soil daily supplied by the city, it occasioned, even at that period, great inconvenience both with regard to conveyance and dessication, on account of the existence of a stratum of water, the height of which, varying according to the season, often reached the level of its basin. A part of the fluid in excess might, it is true, have been turned into the little brooks, which spring up at a short distance, but as these brooks all run into larger streams and cross several villages and private properties, and indeed the town of St. Denis, would have caused just complaint on the part of a manufacturing population of ten or twelve thousand souls, for which the water is required to be extremely pure.

It was in order to surmount these difficulties that the contractors for the Bondy Laystall, stimulated by examples to which we shall hereafter have occasion to refer, thought of turning into the earth, at a considerable depth, the superfluities of their reservoirs. M. Mulot, C.E., was in consequence charged with the boring of an artesian well, intended, not for the purpose of bringing water to the surface of the earth, but to absorb that which should be sent down its shaft. This attempt was crowned with complete success; the boring having been carried to a total depth of 243 feet 7 inches, (74 m 71) showed two absorbing strata, one from 133 feet 5 inches to 155 feet 4 inches in a mixture of chalk and silex, and the other from 214 feet 11 inches to 243 feet, in argillaceous sand, and green and grey sands containing lignites and pulverised shells. By the first, 60 or 70 cubic yards were absorbed in four and twenty hours, and by the second 140 cubic yards in the same time.

The Prefect of Police, alarmed at the consequences which might arise, affecting the salubrity of the waters under the surface, from such a large mass of dirty fluids being mixed with them, ordered the process to be suspended until a committee of the Board of Health had examined into its operation.

In the Paris basin are several distinct strata of water, separated from each other by impermeable layers of different kinds. The first, that is to say the most superficial of these strata, is not to be found under the city of Paris; it is only met with on the tops of the hills and plateaux which surround it on all sides; it is retained by a thick bank of clay which is found above the masses worked as plaster quarries. For this reason, on these plateaux, 600 feet above the level of the Seine, the wells are often only two or three yards deep. This stratum is evidently formed by the filtration of rain, and by the condensation of vapour on the surface of the soil of the plateaux.

The second stratum, which probably depends on the same causes, but which extending under Paris and throughout the valley of the Seine near it, collects its waters from a much larger surface of country, and flows across sands which are between the plastic clay, and the building chalk (*calcaire à batir*, wanting in the London basin). It supplies all the wells in Paris, to the number of twenty-five or thirty thousand.

The strata of water below the two first can only be reached by boring: their number and the depth at which they are to be found vary to a great degree; sometimes they are entirely wanting, they do not always ascend, and if they reach the surface through the well, their overflow is not the same in places nearly contiguous. It is very important to be observed that these strata are so much the more abundant, as they are found at a greater depth, and that they have a rapid current, which gives them the character of subterranean rivers.

Numerous facts on the contrary prove evidently that the two first strata have no current, and are completely stagnant. The first, that which is above Paris, is very scanty, and there is a risk of infecting it by sending into it a large quantity of dirty water. To be convinced of this, it is enough to observe that the waters which came from the side of Mount Valerien are excellent, and those from Montmartre are not drinkable on account of the number of cowhouses and dung-pits which lose there all their liquid portions. The second stratum, that which supplies the wells of Paris, was formerly of good quality, and was used for drinking by the inhabitants of the houses, and neighbouring villages. It has only been since the increase of cesspools, and especially since the introduction of privies into houses, that is to say from the time of Francis the First, that the water has begun to deteriorate, and that the Seine water has been obliged to be used for drink. It must not, however, be thought that the influence of dirty and infecting waters extends beyond a very narrow boundary. Thus it has been found that around the great laystalls which were formed by the city of Paris near the barriers of Montreuil and Fourneaux, the well-water was never affected beyond a radius of 150 or 200 yards. The village of La Chapelle near Paris, not being able on account of its situation on depressed ground, to get rid of its dirty water, was obliged in order to disperse it to dig immense cesspools which swallow up all that is thrown into them. Besides a population of four thousand souls, the village of La Chapelle contains an enormous quantity of horses, cows, pigs, &c., and yet the wells near the cesspools have never been infected beyond two hundred yards from them. A still more decisive fact than the preceding is afforded by the history of the laystall of Montfaucon. Towards the close of the last century, before the conduit was made which discharges into the Seine, the surplus of the basins, one of the contractors for this laystall thought of digging in the lowest part a series of wells of large diameter, of which the bottom touched the stratum supplying the neighbouring wells. He succeeded by this means in getting rid of the troublesome water, and the wells around were infected, but not beyond a radius of 200 yards. A very long period is required to enable the gradual removal of water, by means of the alimentary stratum, to cleanse an infected well, of its bad qualities. A manufacturer in the Faubourgh St. Marceau wishing to get rid of the hot water of his steam engine at small expense, thought of sending it into a different well from that which fed his boiler. For some months this produced no inconvenience; but gradually the water in the neighbouring wells got warmed, and at last to such a degree that it could not be used for many purposes. The warm water was obliged to be sent in another direction; but it took *eighteen months* to bring the wells to their primitive temperature. We must add however, with regard to the gradual renewal of the water in the wells of Paris on account of the ever increasing consumption necessary for industrial purposes, that the suppression of the cesspools which the police no longer allow in the houses, and especially the establishment of moveable water closets, or at least with staunch walls, will prove so many causes which will probably in a few years carry off the bad qualities of the well water.

As to the lower strata, their abundance, and the rapidity of the currents which prevail in them, prevent us from assimilating them to wells, or from regarding the deperdition of dirty water, even in any very great quantity, as exercising a pernicious influence. In 1789, the architect Viel being employed by the Hospital Board to free Bicêtre from the rain and household water, as well as from the urine and fecal matters produced by a population of more than four thousand souls, he thought of directing the flow towards some old quarries deep enough to reach the stratum supplying the neighbouring wells. But wishing to have a permanent infiltration, he sought the second stratum by means of a well 15 yards deep from the bottom of the quarry, this well is ten yards broad at top, and ends in a bore of large dimensions, thus forming a cistern with which the several galleries of the quarry communicate. It was in the month of November, 1790, that all the water of Bicêtre was introduced into this cesspool, and from that day it has always run off easily. It is true that the wells situated on the right bank of the small river Bièvre, 150 or 200 yards from this cesspool, have been infected; but that arises from a circumstance purely local, rain water after storms, accumulating in the galleries, which communicate with the cesspool, and exercising an enormous pressure, cause the infiltrations to rise to the first stratum. For the purpose of remedying this serious inconvenience, the Hospital Board ordered a new absorbing well to be bored in a better position, which, since the year 1835, has absorbed 400 cubic yards of liquid, in twenty-four hours. Besides, the infection produced by the other did not extend to a great distance, for all the wells on the left bank of the Bievre, and the well of Bicetre itself, which is used for drinking by the population of the establishment, have never ceased to supply good water.

Notwithstanding the remarkable success attained at Bicetre ever since 1789, a considerable time elapsed before the boring of artesian wells was employed elsewhere for the dispersion of water, which have no drainage on the surface. A few years ago an artesian well having been bored on the Post Horse Square, at St. Denis, it was found that the waters, deprived of easy drainage, caused during frosts great impediment to traffic from the ice produced. This inconvenience had almost caused the plan for a new spring on the Place of Guelders to be abandoned, when M. Mulot engaged with the corporation to *disperse into the interior of the earth, when wanted, the waters brought to the surface after they had been used for such purposes as were required.* The new well was carried to the depth of 70 yards, and in the interior were arranged three concentric tubes like those of a telescope, with this difference that instead of there being any friction, they were separated from each other by a space four inches broad. The water supplied by the deepest stratum is brought to the surface through the interior of the smallest tube; the water of a stratum 60 yards deep is collected in the same way through the space between the smallest and the middling pipe; and the third tube, enclosing all the others, collects and disperses into the third (non-ascending) stratum the excess of water supplied by the two others.

A manufacturer of potatoe starch at Villetaneuse, a small village three miles from St. Denis, by means of an absorbing well, gets rid of the infected water, which had caused such serious complaints as would, very probably, have obliged him to have closed his establishment. The bore was carried to a depth of 70 yards, and during the winter of 1832 and 1833, the well carried off 80 or 90 cubic yards of liquid per day. After it had been in operation for five months, the borer carrying a scoop, with a valve at the end, was sent down, but, to the great surprise of the manufacturer and engineer, only brought up sand and whitish water. This fact, which shows so strikingly the rapidity of the lower currents, is enough completely to remove any fear which might be entertained of the inconvenience of dispersing among these currents such a quantity of infected water.

Relying upon the previous examples the Board of Health recommended the administration to leave the contractors of the Bondy laystall at perfect liberty, and accordingly every twenty-four hours a hundred cubic yards of liquid, charged with a considerable quantity of solid matter are dispersed into the absorbing wells.

An absorbing well constructed by M. Mulot for the city of Paris in 1835 at the Barriere de Combat, and also described in *Magasin Pittorsque* carries off a hundred cubic yards per hour. The contract price was £336 (8,400 francs.)

M. Arago attributes the invention of absorbing wells, as well as of the ascending ones to the French. René, the famous King of Sicily and Count of Provence, had a number of cesspools dug near Marseilles, in the Plain of Paluns, a large marshy basin, which it seems impossible to drain by superficial canals. These holes throw and continue to throw into the permeable strata, lying at a certain depth, the waters which would render the country unproductive. It is said that the water absorbed by the cesspools of Paluns, after a subterranean course form the gushing springs of the Port of Mion, near Cassis. This is the most ancient example of the kind. These cesspools are called in Provensal, *embugs*.

The most important results are naturally expected from works of this nature, which it is anticipated will place new resources within the reach of the engineer. They will afford the means of draining marshes, which otherwise could only be cleared by difficult or expensive processes. The application to sewage is too evident to need inculcation, they will enable us to relieve many small streams, which receive the sewage of large and dense populations, and in every way they give to the engineer abundant promise of being able to contribute in various ways to the improvement of the public health. The extension of the system at Paris is proceeding rapidly, and it is to be hoped that it will be equally introduced in this metropolis, which lies in a similar geological position. The marshy districts of Hackney, Lambeth and Woolwich might be relieved, and instead of Mr. Martin's expensive plan for the improvement of the sewage, the Thames might be much more easily relieved by the filth being turned into absorbent wells. It may be believed that the dirty water becomes disinfected much more certainly, and so returned much sooner into circulation, by being dispersed in the under currents, than in the superficial waters.

CANDIDUS'S NOTE-BOOK.

FASCICULUS XIV.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. It is said that Albert—or as some pretend he ought to be styled, 'His Majesty!' has a great deal of taste for all the fine arts;—and so, indeed, had George the Fourth, the misfortune was that it was—in architecture, at least, intolerably bad, as Buckingham Palace most plainly testifies. But let us hope better things of Albert,—that he will merit the epithet of *Kunstliebend*, and that he will exercise his influence in behalf of that art which most requires it—to wit, architecture. I trust he will have taste and to spare—for there will be many about him not overstocked with it; yet how people instantly discovered that he has such abundance of it, before he has done any thing to show it, is rather puzzling; except that they have taken it for granted, upon the principle that

"All soldiers valour, all divines have grace,
And maids of honour beauty—by their place."

and of course a Prince Consort must be a phœnix of taste and accomplishments,—a second admirable Crichton.

It will be well should his architectural taste induce him to keep his eye upon the new stables at Windsor, and to hint—in whatever quarter it may be necessary, that they ought to be something less disgraceful in design than the Mews behind Buckingham Palace. To say the truth, royalty appears to have been hitherto singularly unlucky in its choice of architects, in this country; which is all the more provoking because it is not Royalty but John Bull who has had to pay for the blunders and execrable designs of such persons as John Nash and Co.

II. However great architects may be in their own estimation, it would seem that they are little better than mere cyphers in that of the world,—such perfect nonentities that their names are of no importance. I lately met with a very florid description of the Prince of Orange's Palace at Brussels, according to which that building is one of extraordinary splendour and taste, yet who the architect was is not mentioned. Neither is such omission by any means uncommon; on the contrary, it seems to be *selon les regles*, and the giving an architect's name to be the exception to the rule. Dr. Granville for instance, not only speaks of the palace of the New University at Ghent, "which for chaste design combined with a rich and imposing style, yields the palm to few modern buildings, and is superior to any erected for the same purpose," but actually gives an elevation of its octastyle Corinthian portico; and yet does not consider it worth while to inform us who was the architect. Hundreds of other instances of the kind might be produced, even from works professedly on the subject of architecture. It may therefore be presumed that, unlike those of any other, the members of this profession are distinguished by a strange excess of modesty;—or if not, they must be grievously disappointed at finding that nobody cares to know even of their existence.

III. Architectural descriptions—or what profess to be such, are sometimes exceeding funny. In those accompanying Pugin's Views of Paris, and *done* by a French teacher named Ventouillac, we read of the front of a building being "adorned by two *perpendicular* ranges of columns," in addition to which curious information, we are assured that it resembles "Palladio's celebrated portico of the cathedral of Vicenza," the Basilica or Palazzo della Ragione of that city being blunderingly converted into a church. Poor Pugin was grievously annoyed at those and other instances of stupidity,—and no wonder; but the publisher was well satisfied that the work was done cheap, and nothing extra charged for such drolleries. It is not always, however, that they manage matters much better elsewhere, for turning over an Italian journal to-day, I met with some account of a book entitled "Quadro Storico dell' Architettura, dal Marchese Malespina di Sannazaro," where it is stated that St. Peter's was *begun* by Michael Angelo, and completed by his pupils and successors, among whom the principal one was Bramante!!—What a truly ingenious and delightful way of writing—or rather mystifying history! I know nothing to be compared to it except the following wicked bit of quiz: "Hannah More, the daughter the late of Sir Thomas More, who was beheaded in Utopia, was the author of Little's Amatory or Inflamatory Poems, to the infinite scandal of her worthy brother the present Sir Thomas, well-known in the religious world by his work entitled Practical Piety, and by another entitled "Cælebs in search of a Saint in petticoats,"—or this other, "The *Lousiad* of Camoens was written by Pindar the celebrated Greek poet, who lived in the reign of George III."

IV. There is a Finnish proverb which says, "Charming girls, lovely maidens!—where then do all the cross ugly wives come from?"—and which is not wholly inapplicable to architecture, since it is no less unaccountable where all the ugly, tasteless, paltry buildings and designs we behold, come from, when we read of the host of talent there has been and continues to be in the profession;—of the taste of such a man as James Wyatt, of the classical genius of Sir —— ——, of the imagination of John Nash;—or of the transcendent charms of any of those orthodox styles, which in our extreme affection for them we not only adopt, but generally take care to make our own by the patriotic process of Cockneyizing them into the bargain.

V. It is odd that though there are Doctors of Music, there should be no Doctors of Architecture. Perhaps it is because architecture is supposed to be in so sound and healthy a state as to require no doctoring. And yet, neither Mr. Joseph Gwilt, nor Mr. Welby Pugin seems to be of such opinion: on the contrary, both of them are for administering to it pretty strong cathartics. Surely they are entitled to add A.D., (*i. e.* not Anno Domini, but Architecturæ Doctor) to their names. There is also a certain scapegrace Candidus, who some will say, might be similarly distinguished, yet others may think he has far more of the Surgeon than the Doctor in his composition.—After all, perhaps it will be said that if Architecture has no Doctors, it has a tolerable number of Quacks.

VI. Vorherr, a living German architect, has a singular crotchet in regard to what he names *Sonnenbau*, which is that all sitting and sleeping rooms should invariably be made to face due South, having only staircases, passages, store-rooms and such places behind them. The reasons he adduces for it are satisfactory enough, and the chief objection to his scheme is that it is utterly impracticable, at least in towns: for supposing all the streets were made to run from East to West, and to be of such width that the shadow from the houses on the South side would never fall upon the opposite ones, it would be only these latter that would have their fronts, or at least their dwelling rooms facing the street, for the rest would have such rooms looking towards the garden or courts behind them—that is behind, as regards the street. This however I myself should consider no objection—rather a recommendation, because I could never understand what pleasure there is in standing at a window to stare or be stared at by your opposite neighbour. Indeed I should say that those houses would have the advantage whose sitting rooms were turned from the street, because they would not be exposed to the noise from carriages, &c. But then, unless the backs of those houses were made to correspond with the fronts of the opposite ones, the streets themselves would make a very strange appearance, presenting a row of fronts on one side, and irregular exteriors on the other. Besides which, much greater extent of frontage towards the street would be required for each house, as the houses must be long and shallow, in plan, instead of being as at present, narrow and deep. There is yet another difficulty standing in the way of such scheme, which is that were all the streets of a town made to run from East to West, there must be lines of communication between them from North to South, which according to such plan would be entirely between dead walls—that is, the ends of the houses in the streets, and the walls enclosing the gardens and courts, or whatever the intermediate space might be between the parallel rows of houses. I may therefore venture to say that *Sonnenbau* will, notwithstanding all its advantages, never come into fashion in London, even if it should anywhere else.

THE PATENT CONCRETE.

Sir—I have read an article in your Journal for the month of January last, describing the works in progress in her Majesty's Dock-yard at Woolwich, wherein it is said that the "*Patent Concrete of Mr. Ranger was found insufficient to keep down the Land Springs.*"

Although the assertion may be correct as far as relates to the work in question, viz., the dock which was constructed of that material, at Woolwich; yet, as such an assertion appears to question the efficiency of the patent concrete, I beg to state to you my decided opinion that the failure arose from a deficiency in quantity, and not from any defect in quality; from an improper manner of applying it—in fact, from a misdirected economy—the excavation being only lined as it were with concrete to form the bottom and the altars, instead of the earth being taken out of such dimensions as to admit of the concrete forming a solid spandril under the altars, (the back line of which should be perpendicular from the outside edge of the dock coping), and of having at least 7 feet in depth under the bottom of the dock. This will be better understood by the following figures.

These are not given as *correct* sections of the dock in question, but as diagrams sufficiently accurate to illustrate the accompanying observations.

Fig. 1.

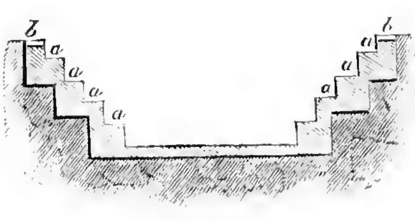


Fig. 2.

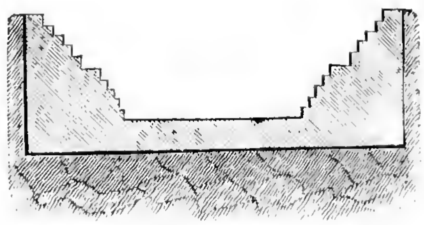

Figure 1 is a section of the dock as executed, where *a a*, &c. represent the altars, and *b b* the coping, the concrete at the bottom of the dock being about 2 feet 6 inches in thickness. By this figure it will be seen that unless the ground under the altars is of a very firm kind, such as good gravel, the weight of the concrete in the altars (being of equal specific gravity with Portland stone,) must cause a settlement, as they are in effect all overhanging, and the whole of the work, supposing each side to settle, (which may well be expected in such soil as that of Woolwich Dock-yard), would open somewhat similar to a book; and it is quite plain that any settlement of the altars would have an injurious effect upon the bottom, unless it was made of a depth much more considerable than it was in the present case, where the thickness was not more than one-third what it ought to have been.

Figure 2 shows the dock as I conceive it should have been constructed. Here it will be seen that the mass of concrete is about three times the sectional area of that in fig. 1, and I feel convinced that if this section had been adopted, no failure could possibly have taken place.

It may be here remarked, that in the construction of docks built of stone, the backing necessarily must form such a spandril as I have mentioned, and this is generally composed of bricks and cement; and why this solidity of form should have been departed from in the section of the dock in question, appears to be altogether inexplicable—and the more so when it is considered that Woolwich Yard is perhaps one of the very worst places in which so rash a step could have been hazarded.

With respect to land springs—I apprehend they may be expected generally to be troublesome in the progress of works in a Dock-yard, where the local pressure from high-water in tidal rivers, or from the sea, is calculated to increase the difficulty, so much so that the greatest ingenuity will sometimes be required to beat the enemy, even though granite and brickwork in cement be used.

I have lately seen a paper describing the method of treating springs as pursued by Mr. Ranger, at Chatham, where I find that gentleman ingeniously collected them by means of cast-iron chambers into pipes, and conveyed them into an adjacent culvert, by which they find their way into the Weir of the Dock-yard engine.

I have been led into these observations from an apprehension that the unqualified assertion, "the patent concrete was found insufficient to keep down the land springs," might be so conclusive to many persons who are not acquainted with its excellent qualities, as to prevent further inquiry upon the subject, and carry a conviction of its unfitness as a building material; while, on the other hand, I think that an examination of the subject will prove its peculiar applicability to the purposes of dock building, or any other massive work where the locality affords good gravel and lime.

At a future period I may return to this subject, and show the great economy of this material, as compared with granite and brickwork in cement; and I think it will not be difficult to show that two docks may be built of concrete, for one of granite and brickwork, and each of them equal in usefulness and stability, which must be considered a matter of no small moment in dock-yard economy at this period, when it appears so difficult to obtain from the rigid hands of our legislators, any adequate amount to be expended in those most important places.

I am, Sir, your obedient servant,

B. T.

Dublin, 14*th March*, 1840.

TOPHAM'S PATENT SLIDE-VALVE COCKS.

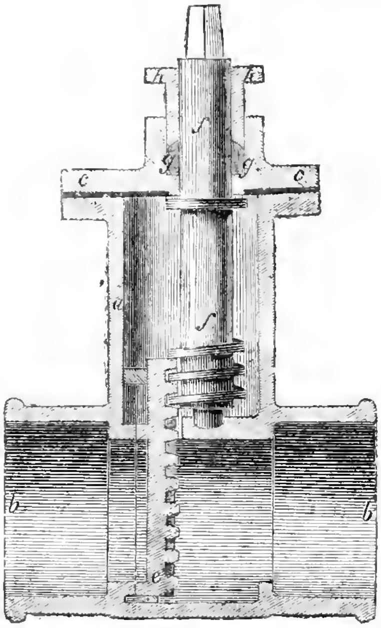

Fig. 1.

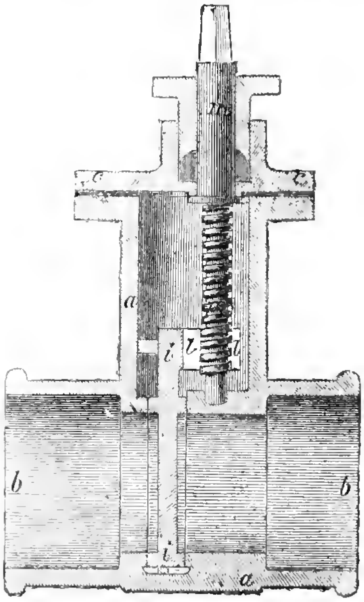

Fig. 2.

DESCRIPTION.

The outer case, in which the slide-valve is enclosed and worked, consists of a box, *a a*, with socket outlets, *b b*, cast in one, and a cap, *c c*, secured to the box by means of four wrought-iron bolts, the position shown at *d d d d*, in figures 1, 2, 3, and 4. Fig. 1 represents a vertical section of one form of the patent cocks, and fig. 2 is a plan of it with the cap off; *e e* is the slide with a rack cast upon the back of it; *f f* is a cast-iron spindle, with a screw cast upon it; *g g* is the stuffing-box; *h h* is the gland. This cock is intended only for what are termed *single*-faced cocks.

Fig. 3 is a vertical section of another form of the patent cocks, and fig. 4 is a plan of it with the cap off; *i i* is the slide with the double face, and with lugs, *k k*, cast upon it, to receive a female brass screw-nut, *l l*, and a wrought-iron square-threaded screw spindle, *m m*, as in the common double-faced screw cocks.

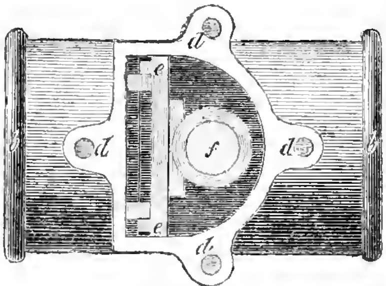

Fig. 3.

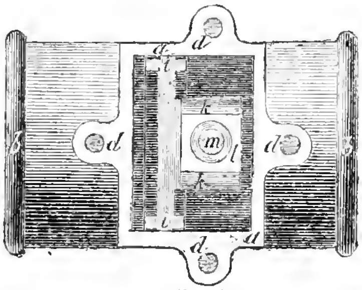

Fig. 4.

Observations.—In the screw cocks commonly used, the box is cast in two pieces, and the outlets are generally made with flanges, to which a socket and spigot piece with corresponding flanges are bolted. It is a well known fact that cast iron is not so liable to corrode as wrought iron, and therefore that dispensing with numerous bolts and three lead joints, will not only render the casing more durable, but enable it to be made at less cost. The side joints in the box or casing sometimes yield unequally; this prevents the slide shutting close to the face, thereby allowing the cock to "let by:" this is prevented by dispensing with the joint. Some cocks of the *smaller* sizes have heretofore been cast with spigot and socket instead of flange outlets; in the patent cocks, sockets are cast on both ends of *all* sizes; although it might originally have been supposed that by removing the cock, and leaving the flange, spigot and socket attached to the main or service, a new cock might have been introduced without breaking the main or service; *in practice*, when a new cock has to be introduced, the main or service *is* broken, and the junction formed by a double socket: it is therefore evident that the separate spigot and socket castings with flange joints are unnecessary. In the single-faced cock, the reason for introducing a cast iron screw and rack instead of a wrought iron screw, is that cast iron is less liable to corrosion than wrought iron, and therefore more durable.

The advantages of the patent cock are its simplicity and greater durability, (owing to there being fewer joints,) and cheapness. The facings of the cocks hereinbefore described are iron; if, from the nature of the water, cast iron is liable to corrode rapidly, the socket or sockets for single or double-faced cocks are made to screw in, and can therefore be faced with brass. The water supplied by the Water Works Companies in London, is of such a quality that *corrosion* of cast iron is very slow, and the extra expense of brass faces, or gun-metal screws, would be greater, when the interest of the money expended is taken into account, than the renewal of the cocks when rendered useless by corrosion.

Mr. Wicksteed, the engineer, has introduced these patent cocks into the services of the East London Water Works, and in a certificate dated Nov. 23, 1838, he states, that

"The chief difference between your patent cocks and those commonly used, consists in the body of the cock being cast in one, and the outlets in cocks of *all* sizes being cast on the body, instead of having flange, spigot and socket pipes attached thereto. By this means you undoubtedly not only dispense with the greatest portion of the lead-joints and screw bolts ordinarily required, and in consequence reduce the cost also, but the slide will be less liable to get out of its true working position, which it is apt to do from unequal yielding of the side-joints; and thus the necessity and expense of repairs, which have been rendered hitherto necessary, will be dispensed with. Although the application of the cast iron worm and rack may not be new, it is certainly not in general use: and, in single-faced cocks, may be used to great advantage. It will, in my opinion, be more durable, and is more simple, and less expensive, than the *wrought* iron screw spindle and *brass* screw nut.

"My experience inclines me to consider the use of brass facing in cocks, where Thames or River Lee water is used, unnecessary, as I know several cast iron sluice gates, with iron facings, that have been worked, and exposed to the action of these waters, for a period of nearly thirty years, that are now in as good a state as possible; the faces are not at all corroded, and the gates are water-tight. I therefore consider the use of brass, in such instances, as unnecessary and expensive. Nevertheless, should the water contain salts that would affect cast iron so as to injure the faces, the mode you propose in your specification, for facing with brass, appears to me well calculated for the purpose, without affecting the principle of dispensing with the side and other joints and bolts."

Mr. Wicksteed has furnished Mr. Topham with another testimonial of recent date, March 16, wherein he states, that

"After having used your patent cocks constantly for two years, I feel enabled to speak as highly of them as I did in my letter to you dated Nov. 23, 1838, and would strongly recommend their general adoption."

AMERICA.

INTERNAL IMPROVEMENTS AND PROSPECTS OF THE PROFESSION.

[The following article has been forwarded to us by our highly valued correspondent at New York, it was written for the American Railroad Journal, and is well deserving the perusal of the Engineers and *Government* of this country, many of the remarks are equally as applicable to the latter as they are to the American Government.]

The attempt to form an Institution of Civil Engineers, has, we are sorry to say, failed. We are not, however, without hopes that another effort, more successful, will soon be made. We have heard a variety of opinions on this important project, and, earnestly as we desire its success, we must admit that there are difficulties in the way, which it is much easier to point out than to overcome. In the first place, it seems impossible to fix on any place where the leading members of the profession could meet even once a year, far less every week, as in London. The public works of the United States are scattered over such an immense extent of country, that there is probably no point where even half a dozen engineers, in charge of as many works, could meet even monthly. If we are right in this view, it is evident that the plan which succeeds so well in England, or rather in London, is not adapted without modification to this country. Then, again, the distinction between Members and Associates would lead to endless contention, though all will admit that some such division is both necessary and proper; but where to draw the line is the grand question. They who have held the rod, have carried the compass and level, have surveyed hundreds of miles for railroads and canals, and superintended the construction of not a few, are not pleased with the idea of being ranked with those who, having failed as lawyers, doctors, store-keepers, or office-hunters, "turn their attention," as the phrase is, to civil engineering, and who, in only too many instances, have at once received appointments to which they should have looked after five or six years arduous service in the field in the various grades of the profession. More than one of our readers could, without much difficulty, point out men in the situation of Residents, or even higher, who would be puzzled, if directed to take the goniometer into their own hands, and run out a curve of a given radius, to join two tangents given in position, while the same feat constitutes one of the very easiest duties of their assistants—the unpresuming title of those who do almost everything. There is a very large class of assistants in the United States who, from want of education, or subsequent aversion to study, or both, are unable to reach the highest stations of the profession, to which their long experience and practical skill fully entitle them. It is only when acting under men who combine liberal and scientific attainments with the proper experience, that this large class of eminently useful engineers can ever attain their deserts, and it does appear reasonable to suppose, that they would derive great advantages from a well-constituted institution, where their industry, skill, and perseverance would be honourably registered by those who are alone capable of appreciating them. On the other hand, young men of superior talent or acquirements, have only to offer original communications to the Institution to be immediately known, and to be at once installed into the very position to which they are by their merits entitled, being neither ruined by injudicious flattery nor chilled by neglect. How different are the means by which a young engineer now seeks to rise in his profession, on the Government works, in which are included nearly all the works of this country. His political creed, and the number of votes he and his friends can command, would far outweigh the professional claims of a rival who might unite in himself the genius of all the engineers of the age; and this is the grand obstacle to the advancement of the profession in the United States.

We will briefly allude to the manner in which many works are "got up," more especially in the Western States. A "celebrated engineer" is employed to survey a railroad from 100 to 500 miles long; he makes a "highly favorable report" to the Legislature, on the strength of which they "authorise a loan," and "locate the line," though it is known to every well-informed man in the State, that the work cannot be put into operation for less than three or four times the original estimate, and when it is capable of demonstration, that the country cannot possibly furnish business enough to keep the work in repair and pay interest on the loans, far less pay anything towards diminishing the debt, until the population has increased at least ten fold—say in from 50 to 100 years. Now it is obvious, that such men as Walker, Brunel, Stephenson, and a host of others in England, and we are proud to say, not a few in this country, whom we do not feel ourselves at liberty to name, are found utterly impracticable in such cases, and they are consequently avoided with as much care by the projectors of works to be built on the credit of the government, as they are zealously sought for by those who project works to be executed by the expenditure of their own actual capital. The evil of employing men incompetent from want of education, practice and character eventually recoils on the State; hence the financial difficulties of all the States who have largely embarked in the construction of public works.

The State of New York furnishes some very instructive examples. By dint of much management a law was passed some years since, that, if a certain canal could be made for a million of dollars, it should be forthwith undertaken by the State. An engineer was immediately employed to survey the route, and he reported, that the work could be constructed for nine hundred and ninety odd thousand dollars, though this was only at the rate of one half the actual cost of a similar canal, presenting fewer engineering difficulties, which had just been completed. The insufficiency of the estimate must have been as well known then as now, still, the law had passed, and the engineer had reported "favorably," so the million was spent, and a million and a half more was then required to complete the canal in the cheapest manner. Three years after handing in an estimate for the enlargement of the Erie canal, the following reasons are given for requiring 100 per cent. additional. "A uniform plan" was not "adopted in the estimates," "and not much reflection had probably been bestowed on the particular manner in which the work should be done." It is also very properly observed, that frost is a very destructive agent in Northern climates, that a large canal requires stronger banks than a small one, and that work done in the winter costs more than in summer—all which would have readily suggested itself to individuals about spending their *own* money, even had it escaped the penetration of *their* engineers for two or three years.

Again, the Croton Water-works, nominally city works, though such no further than that the city pays for them, will contribute their mite towards developing the wonderful facility with which government engineers adapt professional opinions to the wishes of government commissioners. We must premise that the water commissioners had, till last year, delayed fixing on the plan for crossing the Harlem river, the most difficult and important work on the whole line. The plan then brought forward was opposed by certain proprietors of lands on the river, and the legislature decided unanimously against the commissioners, though the party to whom they owed their existence had a large majority in one branch—a case nearly unparalleled in New York legislation. The use of iron pipes for crossing, by means of an inverted syphon, the commissioners' plan, was unnecessary, with the high bridge prescribed by the Legislature, but, as the former are as averse to being interfered with as they are prone to interfere with others, they have announced their intention of complying with the law no further than absolutely necessary, that is, they will keep the aqueduct 12 ft. below grade and use the pipes. We quote their own words:

"The bill as revised, * * * is in substance as follows:—the aqueduct to be constructed over the Harlem river, with arches and piers, the arches in the channel of said river to be at least 80 feet span, and *not less* than 100 feet from high water mark to the under side of the arches at the crown.

"The original design of a high bridge, as designated in our report of January, 1838, required arches of 112 feet in the clear above high water mark, which is 12 feet more than that required by the Act of May, 1839. A bridge, therefore, of 100 feet height of arches above tide, will have to be passed by iron pipes or syphons, to accommodate the ascent and descent of the 12 feet from grade. This bridge will be more economical in its construction, and not subject to so many contingencies, from its less elevation, as the plan originally proposed. The parapets will only be 114 feet in height, which is 17 feet lower than the plan of 1838; and as the arches are thus reduced in height, stone of a diminished thickness may be used. It is proposed to carry the water over the river, at the commencement of supply, by two three-feet pipes, adopting the work, however, to carry two pipes of four feet diameter, when the city shall require it. *The same arrangement for pipe chambers, and waste cocks, will be required in this structure, as was required for the syphon bridge formerly proposed.*

The engineer echoes, "In relation to the bridge, the law prescribes that the arches in the channel *shall be* 100 feet at the under side of the crown, above common high water mark of the river, and *not less* than 80 feet span, conforming in these respects, we are at liberty to make the plans in all others, without restriction from the law.

The arches of the bridge originally designed to maintain the grade of the aqueduct, were elevated 112 feet above the high water mark of the river, which is 12 feet higher than the *Act requires*. It is obvious, therefore, that 100 feet will not be sufficient to maintain an aqueduct of masonry, but *will require* iron pipes as conduits for the water. This I do not consider an objection, as I am fully satisfied iron pipes will make the most suitable conduit for the water on such a bridge, and therefore have had a plan prepared, with a view to comply with the law, and avail of the economy and greater permanence from a less elevated structure. The less height required for the arches, and by adopting iron pipes for the conduit, the top of the parapets will be 114 feet above high water mark, which is 17 feet lower than the original plan. The superstructure being lighter than necessary for an aqueduct of masonry, a *diminished thickness* of arch stone may with equal safety be adopted."

We should be pleased to know what diminution in the depth of the arch-stones this change of plan would justify, as well as the saving in cost, which latter, we strongly suspect, it would be difficult to express in the constitutional currency of the United States, without an extension of decimals several places to the right of "mills."

The following extracts, though trifling in themselves, go far to show the estimation in which the profession is held by government commissioners.

"Notwithstanding the oversight of the inspectors and engineers, the work will, in a few cases, be carelessly performed; and it is only by the correcting influence of these repeated tours of inspection, made by the commissioners and principal engineers, that we can be certain the work is performed in a manner which will ensure its stability and imperviousness."

If the citizens of New York have no better guarantee than this, that the work has been faithfully superintended, that 4th of July on which the Croton water will be "regaling the taste and sight of our citizens," will be simultaneous with the millennium.

At p. 255, April number 1839, Railroad Journal, will be found the following cool assertion :

"The locks on the Chenango canal, which are 111 in number, are (with the exception of five stone locks) all of them composite. They were built under the direction of Mr. Bouck, one of the present canal commissioners, and their average cost was 3,808·50 dollars each."

We shall next be informed that the piers of the Potomac aqueduct have been successfully carried up under the direction of Mr. Forsyth, and that the Thames Tunnel has at length been completed under the superintendence of his prototype Lord Melbourne.

We refer to these circumstances only as effects of the policy of allowing the government to enter into the pursuits of individuals, and not with the design of insinuating that the mortifying reports of many government engineers are the *cause* of the present state of the profession, but simply to show that they are the legitimate consequences of the pernicious interference of the State Governments with that in which they have no more right to engage, than they have to establish theatres or hotels and then forbid any citizen from competing with them, on the miserable plea, that all the people of the State are interested in their tavern-keeping monopoly, that it bears equally on all, and is, to use the logic of governments, *therefore* just. The pecuniary difficulties in which most of the States who have engaged in railroad and canal speculations find themselves involved, will necessarily break down the entire system of State works, and their complete abandonment will, more than every thing else, conduce to the welfare, honour, and usefulness of the profession.

The success which has attended the expensive and well constructed railroads about Boston, is the most encouraging fact we have to record, and it is worthy of remark, that the stocks of those roads were the only stocks not affected by the bursting of the biennial bubble grandiloquently called the "late crisis." The Eastern railroad has been opened to Salem, and the number of passengers is already twice that estimated before the opening of the road, and on which the project was based. The Western railroad has been opened as far as Springfield. The Old Colony railroad is going on rapidly; the Norwich and Worcester is to be opened about new year's day, and the Housatonic railroad some time this month. In this State, the Utica and Syracuse railroad has been opened, and the Syracuse and Auburn railroad put into full operation. In Pennsylvania, the Reading railroad has just been completed, and in Maryland, we believe the Baltimore and Susquehannah railroad has been opened to the public. Two of the above roads have received aid from the State of Massachusetts, but they have all been managed, and, with these comparatively trifling exceptions, have been paid for, by individuals. *We do not know of a single State work having been completed, or in part opened, during the year* 1839.

In New England they have retained too much of the sturdy independence and common sense of their forefathers, to tolerate the meddling of the government in the affairs of individuals, and we seek in vain for a canal, a railway, a machine shop, a lumber or coal yard, owned by a New England State. It has been found impossible to persuade them that they are not as capable as their Transatlantic brethren of managing their own affairs, and the consequence is, that they have the best managed, best constructed, most costly and most successful, railways of any State in the Union. An attempt has been made to regulate the sale of spirits, and has proved about as successful as a previous effort to interfere with another article in the "grocery line"—y'clept "tea."

Some little has been done on the State works of New York, by means of the unexpended balances of former appropriations for the enlargement of the Erie canal, and the construction of the Genessee valley and Black River canals. There is no little curiosity to know how the first is to be disposed of—not only both parties, but every sane resident of the State, who feels an interest in her honour and welfare, being heartily ashamed of his credulity in believing it either practicable with the means of the State, or useful even if practicable. The money already thrown away on this unrivalled specimen of legislative folly, will do something towards opening the eyes of the citizens of this State, and a year or two hence we fully expect to find the enlargement as unpleasant a reminiscence in New York as the suspension is in a neighbouring State.

The lateral canals of the State of New York cannot with propriety be passed by, being "par excellence" government works in their conception, management, and income. As the official report on the Genessee valley canal has been published, we will examine the proceedings of the Commissioners with regard to that work, and our readers, by turning over their files, will be enabled to judge of the accuracy of our deductions. The original estimate of the canal was a little less than two millions, but the present estimate is thus stated in the report alluded to.

"The cost of the canal (excluding 314,520·43 dollars for the Dansville branch,) is estimated by the Canal Commissioners in their recent report, (Assembly Document of 1839, No. 360,) at 4,585,602·36 dollars.

"The canal board are not possessed of all the facts necessary to enable them to estimate with sufficient certainty the future revenues of the canal. They fully appreciate its value to the interesting section of the State whose resources will be developed by its completion. In respect, however, to the tolls to be derived from it in the present state of the navigation of the Alleghany river, the board would observe, that in the year 1835, F. C. Mills, Esq., the engineer who surveyed the route, submitted an estimate to the Canal Commissioners of its probable revenues, (Assem. Doc. of 1835, No. 264, page 42,) in which he computed the tolls, independent of its probable contributions to the Erie canal, at 39,129·60 dollars. Of this amount, 13,207 was estimated for the tolls on the finer qualities of lumber and other products of the forest, which, it was supposed, would seek the New York market in preference to that on the Ohio and Alleghany rivers. A majority of the Canal Commissioners, (including the late acting Commissioner on that canal,) in the report above referred to, have expressed their belief that the amount of 39,129·60 dollars, is "greater than will be realized for at least the first few years after the canal is completed."

Now let us translate this into plain unofficial English, such as is used in the every day transactions of common men, not devoid of common sense. It is proposed to construct a work at the expence of the State, the cost of which is estimated at two millions of dollars, and its *gross* income at less than 39,000, one third of it to be derived from lumber, which, it is well known, will soon be exhausted. The canal is to be 106 miles long, and we know from experience that 39,000 dollars will not meet the ordinary annual expenses, repairs and renewals. We will, however, suppose this sum sufficient for those purposes, then the people of this State are saddled with a "gentleman pensioner," who cannot exist on less than 100,000 dollars per annum. On comparing this, however, with the Chenango canal, it was discovered that the annual deficits of the latter exceeded those of the former by 20,000 dollars, and as the march of the Commissioners was "still onward," they at once decided on such an addition to the estimate as should place the Genessee valley canal as far "ahead" of the Chenango, as the latter was in advance of the other "auxiliary" canals. They determined accordingly on spending five millions on this work, which will entail on the State a permanent annual tax of 250,000 dollars at least.

Now, does any man, out of office, believe that the people of the State of New York would have authorised an expenditure of five millions of dollars on a canal which its friends and projectors assert will not yield more than 39,000 dollars gross revenue, merely for the privilege of having their money squandered by a set of Canal Commissioners? Before seriously entertaining such a project, far less recommending it, they ought to have been able clearly to establish the probability of an immediate income equal to

	Dollars.
Annual cost of repairs, renewals and expenses . .	50,000
Interest on five millions of dollars . . .	250,000
Towards paying off the debt, at least . . .	100,000
Making the total minimum income,	400,000

or ten times the estimated income, the latter being in fact, too insignificant in amount to have any material bearing in discussing the value of an undertaking which is to cost five millions.

Suppose that the State of New York, after expending one million on the Chenango canal, had refused to submit to any further imposition, that canal would be unfinished, its revenue nothing, in place of 20,000 dollars on an expenditure of two and a half millions, practically speaking, nothing; the State would have saved one and a half million, and would only have incurred a permanent annual tax of 50,000 dollars instead of 120,000 dollars, which the people of this State are now paying for the glory of owning the Chenango canal. We give an extract from an article which appeared in the Courier and Enquirer of 7th May last, in which the writer undertakes to prove that lateral canals generally will be nearly useless in themselves, and of little value to the main canal. Whatever may be thought of his *reasons*, it is only too true that his conclusions are fully borne out by the actual experience of this State.

"I have never seen any attempt to explain the causes which render the lateral canals unable to pay expenses, though it appears to me to be by no means difficult. The policy which led to the construction of these lateral or auxiliary canals, has no analogy with that which influenced and guided the projectors of the Erie and Champlain canals. The immediate object of the former, was to open to the husbandman the extensive and fertile region of western New York ; that of the latter, to bring within reach of the city the forests of the North. Both have fully succeeded—not because there are no other such routes "in the world," but—because they were projected in such a manner as to open the greatest possible extent of country, and without reference to mere local interests. With the lateral canals the case is widely different, for it is evident, that the main canal will command the business of the country through which it passes, for a certain distance on each side, this in an agricultural country, will vary from 25 to 40 miles according to circumstances; but, whatever distance be allowed, it is clear, that the portion of the lateral canal contained within these limits, will only receive the contributions of those directly on its banks. If the lateral canals be from 80 to 100 miles apart, it will be found, by a few simple calculations of distances, that a very small portion of the country between the lateral canals, and within 40 miles of the main canal, will derive any advantage from the lateral canals. Hence the insignificant revenue of the Seneca, Crooked Lake, Chemung, and Chenango canals. The two first are in the country directly tributary to the Erie canal, one half of the Chenango canal is liable to the same objection, and the other half and the Chemung canal would suffer from the New York and Erie railroad, had they more than a nominal revenue. The Black River canal proper lies within the influence of the Erie canal, and its extension to the Lake or the St. Lawrence will only furnish a slower, more expensive, and more troublesome communication between its termini, than the present excellent one by Lake Ontario and the Oswego canal. Lastly, the Genessee Valley canal, with the Erie canal on the north, and the Erie railroad on the south, bids fair to be second only to the enlargement in disposing of the surplus revenue, or rather to the vast annual deficiencies, which nothing short of an entire change of policy can possibly avert. If the Black River and Genessee Valley canals, estimated at ten millions, be immediately abandoned, the State will lose about 500,000 dollars, which may be considered an anticipation of the payment of one year's deficiencies of these canals when completed, by the immediate forfeiture of which, the State will save a like expenditure per annum in perpetuity, besides the immediate disbursement of a sum nearly equal to the entire cost of the Erie and Champlain canals."

The estimates for these canals have since been reduced, and their probable deficiencies are estimated by Mr. Paige (Sen. Doc. 1839, No. 101, p. 7,) at 150,000 dollars, and if the sum now spent on these works does not exceed two millions, their immediate abandonment will save the State 350,000 dollars per annum—a sum more than sufficient to support the government. We shall have occasion again to refer to the above report, which contains the most sensible view of the public works owned by this state, which has fallen under our observation: and it derives great value from the circumstance that the writer is justly considered one of the ablest men of the party to which we are indebted for the lateral canals and the enlargement, and would naturally be disposed to treat them in the most favorable manner.

It is assumed by Mr. Verplanck and the committee of 1838, that the revenue of the Erie canal will justify an expenditure of 40 millions, and repay the principal in 30 years; while, on the other hand, Mr. Paige, from official documents, undertakes to prove that the revenue will only pay the interest on 15 millions, with every prospect of a permanent debt to that amount. This great discrepancy arises from the fact that Mr. V. adopted the views of the committee of '38, who state in their report,

"It will be perceived that the very foundation upon which the financial calculations of the committee are based, is the estimate of the Canal Commissioners submitted to the Legislature, in which they state that the Erie canal, within a few years after its enlargement, will produce an annual revenue of 3,000,000 dollars. The importance of verifying the accuracy of this estimate will be evident, as any material error would lead to the most injurious consequences."

Mr. Paige, on the other hand, instead of adopting the conclusions of the Commissioners, takes the data on which they either did or ought to have established their income of three millions, and demonstrates that there is no probability of the revenue of the Erie canal reaching this sum till the year 1886, without making any deduction for the partial or total repeal of its monopoly of carrying freight, on which exclusive privilege it was shown in a former number that its *entire surplus* revenue depends. The Governor in his late message, as well as the committees of '38 and '39, have placed implicit confidence in the estimated income of three millions, as reported by the Commissioners, while Mr. Paige goes to work as if he neither knew nor cared about any previous calculations on that subject. We have no means of ascertaining why he who knew the merits of the Commissioners so much better than the other gentlemen, should not have yielded the same credence to their statements; but, be this as it may, he has shown clearly that the estimate of three millions gross income from the Erie canal, is utterly unworthy of belief. We must, however, correct one error in this excellent report. It is said, (p. 8,) "The Commissioners cannot be regarded as estimating that the tolls would amount to 3,000,000 dollars in 1846 or 1849, but at a period much more remote." This unhappy attempt at exculpation had been anticipated by the report of the late Comptroller, which appeared more than three months before the report of Mr. Paige. This officer writes and italicizes the remark, (No. 4, Ass. Doc. p. 23,) "*A few years after the completion of the enlargement* may carry us to 1850." The door of escape for the Commissioners is therefore closed, and we are at liberty to choose, as we please,—Mr. Paige's estimate of three millions revenue in 1886, or the Commissioners' estimate of three millions revenue "*a few years*" before 1850.

After proving the inability of the State to complete the enlargement, and the consequent impropriety of any further expenditures, that same senator, the best lawyer in that body, advocates the enlargement, merely reducing the size from 7 by 70 to 6 by 60, a distinction without a difference—for an expenditure which is wrong in principle, cannot be justified by a diminution of its amount by four millions, or $16\frac{2}{3}$ per cent. the precise amount leading to a long debate. The same course was also taken by another gentleman, who is well known for the manly stand he has taken against lateral, or, as he very properly designates them, "pauper canals," and thus we find two of the most able members of the Senate advocating a work which they know the State can never complete and can never require. As already remarked of the engineers, it is their misfortune rather than their fault, and the inevitable result of the departure of the government from the high duties of general legislation, and its illegal embarkation in the pursuits of individuals, for these same gentlemen, if members of a board of Directors who were expending *their own* money, would be eminent for sagacity, prudence, and candour.

The Governor in his first message admits the evil, but does not, in our opinion, go to the root of it, though, as it was necessarily written before entering on office, he could scarcely at that time have supposed it possible that he was approving of a system of works based on official data, which it is now only too clear, were never entitled to his confidence. He very truly observes,

"With the extension of our internal improvements there has been an immense and unlooked for enlargement of the financial operations and the official power and patronage of the Canal Commissioners and the Canal Board. These operations are conducted, and this power and patronage exercised and dispensed, with few of those requirements as to accountability and publicity enforced with scrupulous care in every other department of the government. So inconsistent and unequal are the best efforts to maintain simplicity, uniformity and accountability throughout the various departments, that a greatly mysterious and undefined power has thus grown up unobserved, while the public attention has exhausted itself in narrowly watching the action of more unimportant functionaries. It is a proposition worthy of consideration, whether greater economy and efficiency in the management of our present public works would not be secured, a wiser direction given to efforts for internal improvement throughout the State, and a more equal diffusion of its advantages be effected by constituting a board of internal improvements, to consist of one member from each senate district."

This plan may be attended with some advantages for a short period, but the very nature of the tenure renders it impossible for the State to command the services of agents with the character, capacity, and acquirements of those employed by individuals and companies, as is only too apparent in this State, from the manner in which the enlargement of the Erie canal, and the construction of the Genessee Valley and Black River canals have been "got up."

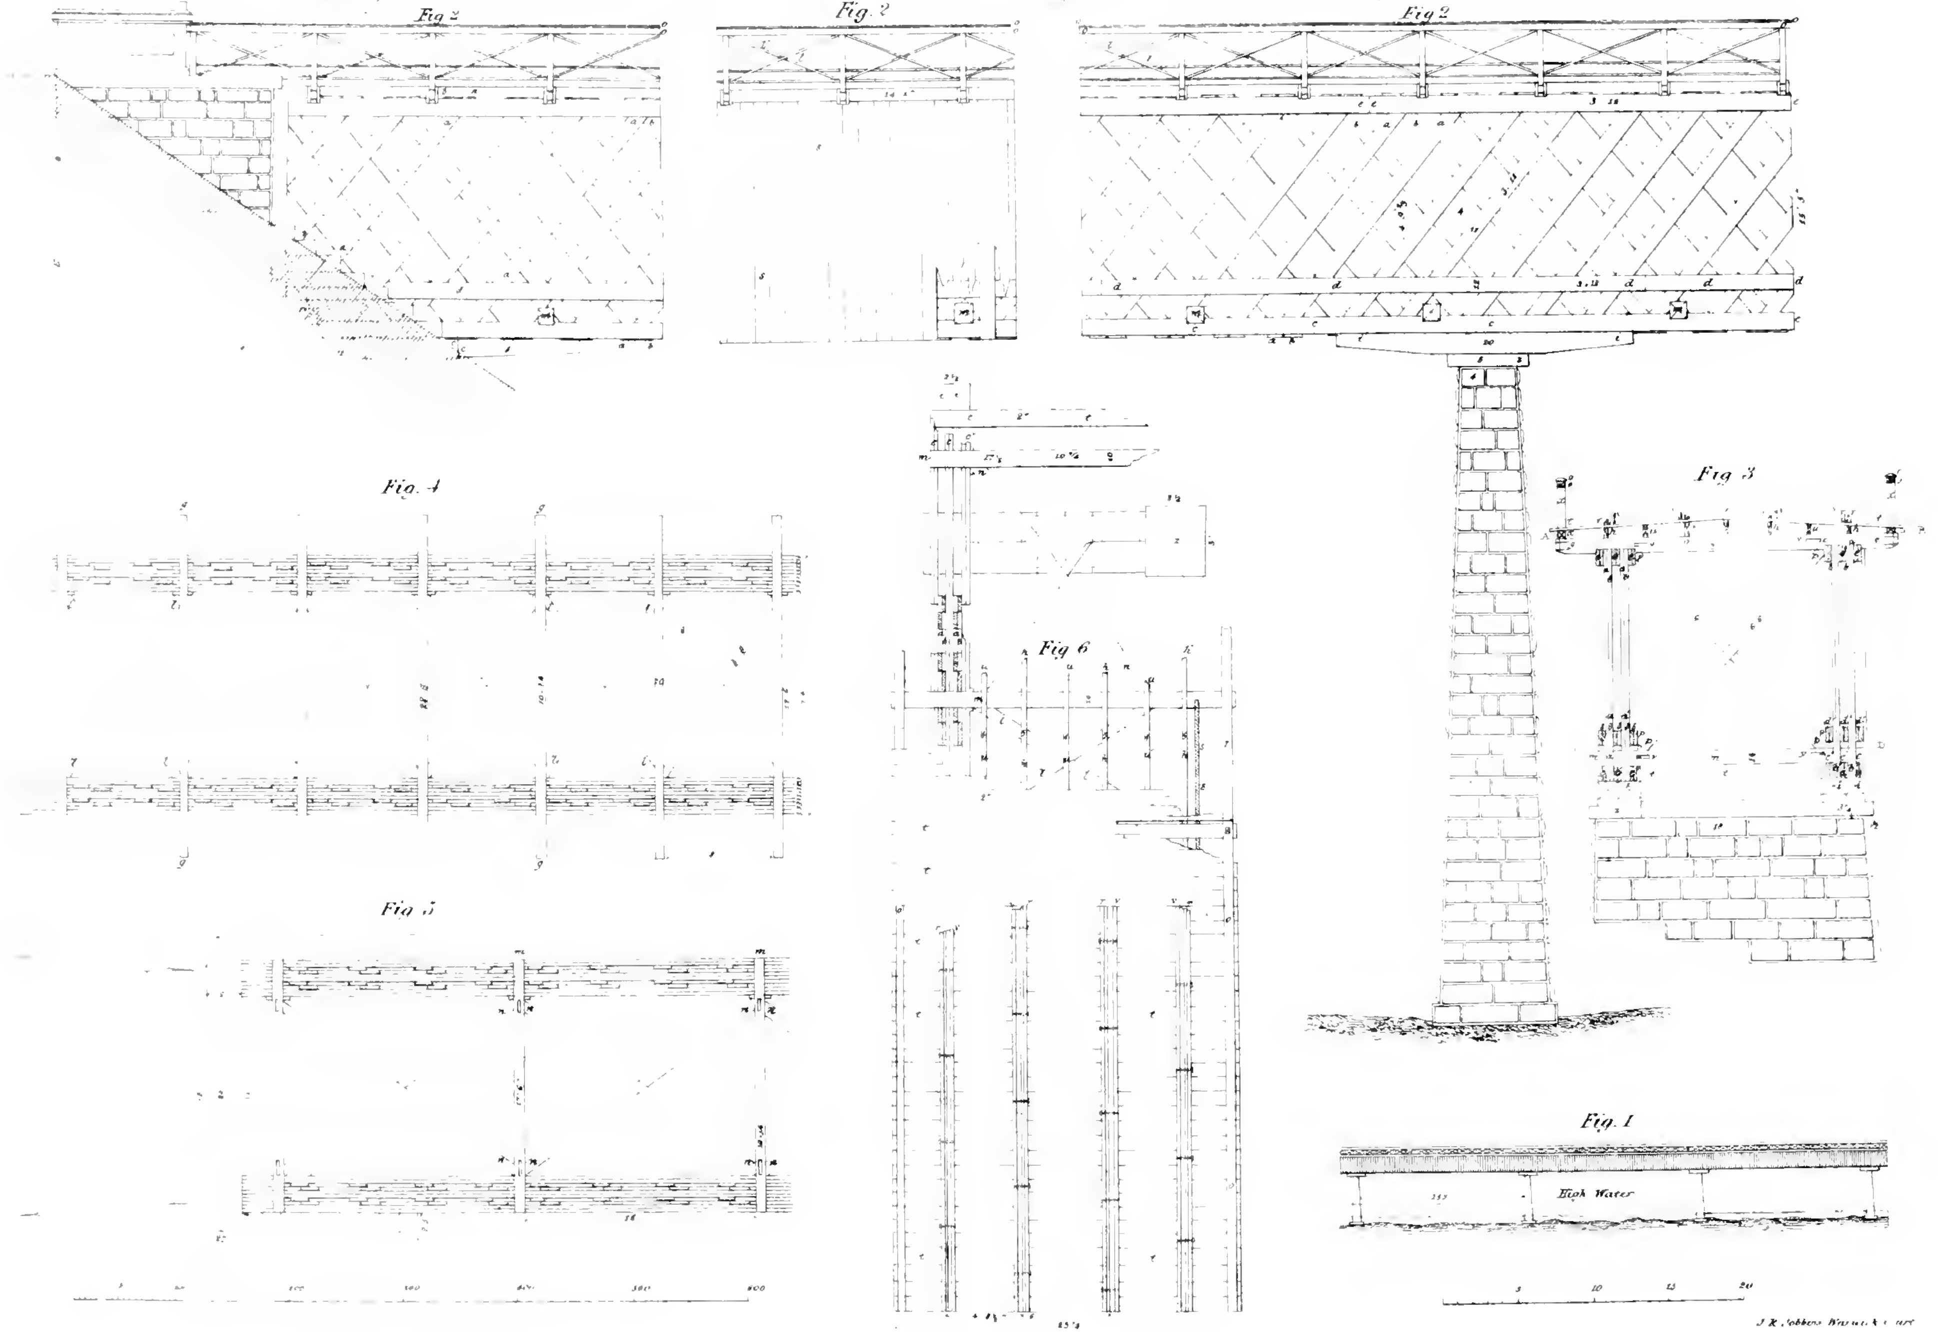
We will briefly allude to some of the Western States. In Michigan, a private company commenced the only important work which can, for many years, be projected in that peninsula—the Detroit and St. Joseph's railroad. The company, however, could not proceed with sufficient rapidity, so the State "assumed the mantle" of Engineer and Forwarder General, and commenced the construction of a "Northern Railroad," a "Southern Railroad," one on each side of the company's road, now the "Central Railroad," and rendered the *system* complete by introducing the "Clinton canal" between the northern and central lines of railway. These four works average very nearly 200 miles each, the sum appropriated or rather the loan authorized for these 800 miles was five millions of dollars, or 6,250 dollars per mile, about one fourth of the sum required to put them into operation, yet the State has actually entered on the construction of all these works. The result is, that the State, after expending all she has been able to borrow, has only 40 miles of the Central (formerly company's) road in operation, her credit is gone for many years, her farmers must be directly taxed to pay the interest on money expended on works which will never be completed, and the *only* work really required is indefinitely postponed. As in the State of New York, the works projected by the government of Michigan were never thought of by private companies, and it would be as difficult to raise by *private subscriptions* to the stock, 5 per cent. on the probable cost of the "Northern railway," of the "Southern railway," or of the "Clinton canal," as it would be to induce individuals in the State of New York to contribute, as a permanent investment from *their own* means, 2 per cent. towards aiding the government in the construction of the Genessee Valley and Black River canals, or in the enlargement of the Erie canal—that is, impossible.

The State of Illinois received from Congress a valuable grant of land to aid in the construction of the Illinois canal, a truly national work, uniting the Mississippi with the Atlantic by the St. Lawrence and Hudson rivers. This donation would have enabled the State to complete the canal, and the nett revenue might have been expended in aiding private enterprise without the possibility of any tax being necessary, even if all the works which they aided should be as unproductive as the "lateral canals" of New York. *Now* they have commenced a "system" of railroads, the aggregate length of which is above 1200 miles! besides other works. It is unnecessary to state the consequences which have followed, any further than to allude to the sale of the State stocks in New York at 50 per cent, and to the special session of the Legislature which has been called to devise "ways and means" to enable that State to meet its immediate obligations. There is much anxiety to know the course likely to be pursued by the governments of Pennsylvania, Illinois and Michigan, and last, though not least, the city of New York. The Croton water-works are exactly as far from completion as when ground was first broken, for the work which, with *any* quantity of money would require more time than *all the rest*, has just been commenced! Had the Commissioners invested the insignificant sum of 2 or 300,000 dollars from their *own* capital, this would never have occurred, and had this undertaking been left to a company, who should have been bound to expend 20 per cent. on the cost of the work from their *own* means, the citizens of New York would be supplied with "pure" water many years sooner, and at one third of the cost which now appears inevitable.

In some States the grand argument will be, that if they can only *complete* the works commenced, a revenue is immediately certain, which will render taxation to pay the interest unnecessary. That the completion of these projects will make the fortunes of many individuals, is well known, but, for the *permanent interests* of the State, the only plan is, to sell out at once with the present comparatively trifling loss. It is impossible to pay too much attention to the fact, that the greater part of the works projected by the governments of the different States, are not such as will ever be of any essential benefit, and when we add to this, that they are constructed at twice the cost of similar works in the hands of companies, are generally much inferior in execution, and always managed and repaired in the most inefficient manner

Bridge over the James River at Richmond in Virginia United States of America

PLATE VIII



J. K. Gibbons Warwick Court

—we shall be at no loss to account for the present condition of State works in general. The deficiencies of this year in Pennsylvania alone, are estimated at 1½ millions of dollars, and except the Erie canal, there is not a government work in the Union which has paid the ordinary expenses, including of course, interest on cost. If the Erie canal be placed on the footing of the canals of Pennsylvania, that is, if its exclusive right to carry all the freight to and from western New York, the western States and Upper Canada be abolished, the gross income of the canals of New York will bear a less proportion to the expenditures, than does the revenue of the public works of Pennsylvania to the annual outlays on the internal improvements of that commonwealth. Notwithstanding their financial embarrassments, we are happy to say, that no other State in the Union has resorted to this mode of giving a "delusive prosperity" to their public works, and there is some reason to believe that the long reign of "exclusive privileges" in this State is about to close. By making immediate arrangements for retiring from the construction of canals, the State of New York may yet escape with trifling loss, and with this object in view, the people would readily submit to the present monopoly of freight from the north and west for a few years longer. This appears to us the most judicious course to be pursued in order to avoid a permanent debt, and it certainly offers an honourable retreat from a position in which it is daily becoming more difficult to maintain ourselves.

The great efforts which have been made by the inhabitants on the line of the New York and Erie railroad, under the most discouraging circumstances, to aid in the construction of that undertaking, show that private enterprize is not yet extinguished in this State, and we have to record the astonishing and gratifying circumstance, that—notwithstanding the different State governments have made every exertion to absorb all the spare capital of this country and of Europe for their own Utopian schemes, the year 1839 has seen more works completed by *companies* than by *States*. Private energy and enterprise have succeeded where the power of government has been unequal to the task, and while the star of "free trade" floats triumphantly on the banners of the Bay State, and indeed throughout New England, we will not despair of seeing, in the Empire State, railways as judiciously projected, as well constructed, as profitable to the proprietors, and as useful to the public, as those of Massachusetts, when they shall be left equally free to the people of the former as they always have been to those of the latter State.

ON TRELLIS BRIDGES.

(With an Engraving, Plate VIII.)

We are principally indebted for this paper to a communication of Mr. Moncure Robinson in the *Revue Générale de l'Architecture*.

Mr. Ithiel Town of New Haven, an architect at New York invented a bridge of a peculiar construction which has much the appearance of a bridge invented here by the late Mr. Smart. The principle is one which has been adopted by Seppings in naval architecture. The advantages attributed to it are that bridges with openings of considerable span may be erected with small pieces of wood. These bridges are built on piers far apart and formed of a truss, if it may be so termed, of continuous trellis work, made of planks, double or treble, 10 or 12 inches wide, and 3 to 3½ inches thick, placed parallel to each other at an angle of about 45° to the horizon, crossing nearly at right angles, and alternating from right to left. The angle at which the trellises cross is not strictly a right angle, for the interstices form a kind of lozenge, which if three feet long would be about 2 feet 9 inches broad, which are about the general dimensions. At the crossings the planks are secured with pins. The bottom of the trellis work is strengthened on each side by string pieces running from one end of the bridge to the other, and made also of small pieces of timber 12 inches by 3, in lengths from 35 to 40 feet. The string pieces on each side of the trellis work are double, so that each trellis is secured by four pieces of timber, six inches thick on each side of the trellis. The joints being equally distributed throughout the length of the string piece. At the top of the trellis is a similar string piece running in the same manner the whole length. On the lower strings are placed the transverse beams which carry the timbers of the floor. The upper string piece in the bridges which were first constructed carried the roof.

The trellis work is secured at the crossings by pins of sound oak, an inch and a quarter thick, carefully turned on a mandrel. These pins fit neatly into holes previously bored. They are farther secured by a wedgelike pin driven into their centres on each side. This latter precaution is however only adopted on the more expensive bridges. These pins are two in number at the crossings, and four at the string pieces, they are the only means of securing the timbers to each other, as they are too thin to admit of framing. The only iron work in the whole bridge amounts to no more than a few nails and pins used in some of the joints.

Such was Mr. Town's original plan, and we shall now proceed to describe the improvements which have been subsequently introduced. It is evident that on this system the timbers of the floor may be laid either on the upper or lower part of the trellis work. By laying them on the lower part, the sides and roof may be more readily completed, but the other plan, which has been preferred for railways in the United States, admits of the carpentry being strengthened by horizontal and vertical braces, and gives additional security to the bridge. The ordinary wooden bridges, called in America Burr's bridges, after a carpenter of that name who improved them, are so elastic that the trains can only pass over them very slowly, while on good trellis bridges, particularly those made by Mr. Robinson, locomotives can run at full speed, a great advantage with regard to railways.

The height of the trellis depends on the strength required in the bridge, and necessarily increases with the opening or span. For extensive works where 200 feet span is required, the trellis is made 17 or 18 feet high. Mr. Town recommends that in most cases the height of the trellis should be a tenth or twelfth of the span. When the flooring rests on the string piece the height of the carriages will not admit of the trellis being less than 13 or 14 feet. Some of these bridges have been built of 220 feet span.

Throughout the timbering the two lines which present the greatest resistance are directed, one, following a horizontal right line lead by the lower extremity of the timbering: the other, following a curved arch, which rests by its two extremities on this right line. The trellis bridge has great strength at its base on account of the string piece formed of four pieces secured two and two; but it is not so strong along the upper curve described by the ideal line of the greatest thrust. The more the trellis is raised, the more the upper string piece, which strengthens the timbering, differs from this ideal line. It has therefore been observed that trellis bridges of large span are apt to settle; and once bent, they lose much of their strength. Mr. Town proposed several ways of remedying this inconvenience. To increase the resistance of the trellis, it may be doubled on each side of the bridge; this Mr. Town has tried, separating the pieces of which it is composed, so that the horizontal diagonal of the lozenge between four adjacent trusses should be four feet six inches, instead of three feet. This increases the cost of the wood of each side of the bridge 50 per cent., but on two-way bridges Mr. Town gets rid of the trellis work which he used to place between the two-ways, the quantity of wood remains the same. The string piece may be strenthened by repeating it at the crossing immediately above the pieces of the trellis. In the bridge at Richmond these two methods of strengthening the timbering have both been used. By laying the flooring on the top of the timbering, and by having open bridges, as previously observed, a means of preventing the settlement is obtained, by interior braces. Besides the weight of the roofing is got rid of, which is of little good for railways, where it would be more likely to catch fire from sparks. This danger is particularly to be feared in America, where wood is burned by the locomotives, and so more dangerous sparks are produced than from coke.

Trellis bridges are of the greatest use in the United States, because being formed of thin planking, they can be built in a short time. Thus, for instance, the viaduct by which the Philadelphia and Norristown Railway is carried over the Wissahicon, 78 feet above the bed of the stream, and 183 feet long in three spans, was built in 68 days. For the same reason the wood required for the trellis work, being easily conveyed, costs less, in many cases, than that required by any other kind of wooden bridge. On the Pottsville and Sunbury Railway, in Pennsylvania, the wood for small truss bridges, for crossing roads is 12 dollars per 1000 feet super and inch thick, which is equivalent to two loads of timber in England. That for trellis work costs only 8½ dollars.

These bridges are formed of pieces all exactly on the same model and of the simplest form, so that all the trusses for the trellis work may be easily cut with exactness by ordinary mechanical means, and the holes bored for receiving the pins. The beams not being at all arched, but flat, it follows that the piers are not subjected to the lateral thrust, to which they are exposed in other bridges; and they only require a thickness necessary to resist the vertical pressure represented by the weight of the bridge.

Trellis bridges are very much increasing in use in the United States; a dozen years ago, one of 2200 feet length in ten spans was built over the Susquehannah, at Clarke's Ferry, near Duncan's Island, just above Harrisburg, the capital of Pennsylvania. One of 1530 long was built over the Hudson, at Troy, in the State of New York, for the railway from Troy to Ballston Spa. The chief spans are 180 feet. It is divided into two ways, each 15 feet wide, and separated by an additional trellis. It is made with the flooring at the bottom, and double trellises at each side. In 1835, others of great span existed at Newbury Port, Northampton and Springfield, all in Massachussetts, at Tuscaloosa in Alabama, at Providence, &c., and since then many more have been built.

The price of the timber for the Troy Bridge, including every thing but painting, is 18·25 dollars per foot. The piers are of fine blue limestone. The flooring is 30 feet above low water. The Tuscaloosa bridge is four spans of 220ft. each over the Black Warrior River. The height of the trellis is 16ft. and it cost 6400*l*. It was opened in December 1834; and has stood well against the traffic which has passed over, particularly large herds of cattle. Another bridge of the same construction of large span is at Nashua, in New Hampshire, thrown over the Merrimack. The bridge across the great Conestogo to carry the Philadelphia and Columbia railway, as it formerly stood was 1412 feet long, and in nine spans of 150 feet. Its breadth was 22 feet, and the flooring rested on the string piece. This bridge was much too weak, the trains could run but slowly on it, and the trusses were only 2 inches thick, so that it has recently been obliged to be rebuilt.

Mr. Robinson prefers trellis bridges, and the many railways he has constructed to those of any other construction, and has introduced considerable improvements into them. That at Richmond is the most remarkable which he has built, and is distinguished as a first rate piece of carpentry, even in America where this mode of construction is carried to such perfection. This bridge stands without the town of Richmond, on the railway from that town to Petersburgh, forming part of the grand line from north to south through New York, Philadelphia, Baltimore, Washington, Fredricksburgh, Richmond, Petersburgh, Raleigh, and Charleston.

Bridge over the James River at Richmond in Virginia, United States.

This bridge was commenced in December 1836, and finished 5th September 1838, it was built by Mr. Sandford, under the directions of Mr. Robinson the engineer. It was erected a little below the magnificent cataract of the James River at Richmond, where the river is very broad, but not very deep flowing over the bare rock which forms an excellent foundation for the piers. The banks on each side of the river are very steep, which rendered it necessary to erect the bridge at a great height above the water.

The bridge is 2,844 feet long between the abutments, and contains 19 openings, which vary in their spans, one span is 130 feet, four 140 feet, four 150 feet, and ten 153 feet span from centre to centre of pier. The superstructure is entirely of timber, erected on the top of piers built of solid granite, rough scabbled on the face, and with rustic grooves at the joints; these piers are only 7 feet 6 inches thick by 24 feet long, on a level with the low water-mark, they batter all round to the top, which is 4 feet thick by 18 feet long on the plan; the height is 40 feet above low water-mark, and to the top of the rails is 20 feet more, making a total height of 60 feet.

Plate VII, fig. 1, is an elevation of the centre arches drawn to a very small scale.

Fig. 2 is an enlarged view of different parts of the elevation, showing the details of construction.

Fig. 3 is a transverse section of the carpentry.

Fig. 4 is a horizontal plan of the carpentry, one part exhibits the rails and floor, another part the joists, girders and wind braces.

Fig. 5 is a horizontal plan of the lower girders and wind braces, together with one of the abutments, and also the top of one of the piers.

The carpentry of the superstructure consists of a continuous double trellis work, 13ft. 6in. high on each side, and running from one end of the bridge to the other, with a triple string at the top and bottom, and another above the lower girders, each consists of two 3in. planks 12 inches deep. The trellis work is formed of 3in. planks 11 inches wide crossing each other and pinned together with two pins at each crossing, and with 4 pins at top and bottom to the string pieces. The whole thickness of the trellis work including the string pieces is 2ft. 6in. and the width between, under the roadway, is 12ft. 6in making a total width of 17ft. 6in. from outside to outside of the trellis work.

On the lower string pieces are placed transverse girders (tie beams) *m*, *m*, 14 by 10 inches, and 17ft. 6in. long and 16ft. apart from centre to centre; on the top of the trellis work are placed similar girders *g*, *g*, 22ft. 6in. long; the extremities of which are notched or caulked down to the top of the trellis work; upon the girders the joists are laid longitudinally, upon which is the flooring of planks inclined from the centre to the sides, the whole breadth of the top of the bridge is 23ft. 4in.

Upon the top of the floor are placed the rails, *r*, *r*, for two lines, they are of timber, 5 inches square, capped with an iron bar 2 inches wide by ½ inch thick, and for the the security of the trains, each rail is provided with a guard rail of a similar scantling, the guard rail at the bottom is in close contact with the rail, but at the top there is a space formed for the wheel, the width between the rails is 6 feet.

Between the upper and lower girders are fixed horizontal diagonal wind braces, *l l* which are morticed into them, there are also vertical diagonal braces, between the top and bottom girders, which render the whole of the bridge very stiff.

On the top of each pier are two capping stones 12 inches thick and 5 feet long by 3 feet 6 inches wide, which project over the pier 6 inches, on these stones are templates of timber to carry the trellis work.

The whole quantity of iron introduced in the bridge is less than a ton weight.

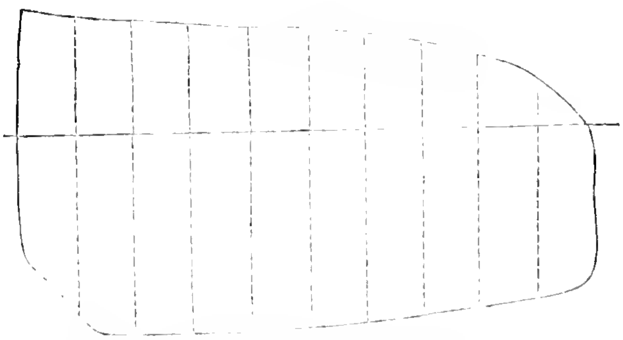
The following table of scantlings will explain together with the references and the drawings, the general construction of the bridge.

Description.	Quantity.	Scantling in inches
Ribband for hand railing *o' o'*	5,800 feet run	2 × 8
Cap ditto, *o o*	5,800 ditto	5 × 5
Posts ditto, *a a*	720 pieces 5 feet long, 5 × 5 and 5 × 8 mean	5 × 6½
Braces ditto, *l' l'*	1,440 ditto 8 feet 6 in. long	2 × 5
Guard rails, *e e*	5,800 feet run	5 × 8
Ditto, *e' e'*	5,800 ditto	5 × 10
Bearings rails, *r r*	5,800 ditto	3 × 5
Ditto, *r' r'*	5,800 ditto	5 × 5
Flooring planks, *t t*, *t' t' t'*	67,200 feet super.	2 × 12
Flooring joists, *u u*	2,900 feet run	4 × 12
Ditto, *u' u'*	5,800 ditto	4 × 10½
Ditto, *h h*	5,800 ditto	5 × 11½
Ditto, *h' h'*	5,800 ditto	5 × 9
Ditto, *x' x'*	5,500 ditto, in pieces 7 feet 7 inches long	7 × 7
Top girders, *g g*	360 pieces 22½ feet long	10 × 14
Top braces, *l l*	720 ditto 15 ditto	5 × 6
Chords or string pieces, *c*, *c'*, *c''*; *d*, *d'*, *d''*; *e*, *e'*, *e''*	2,850 ditto 36 ditto	3 × 12
Lattices, *a a*, *a' a'*; *b b*, *b' b'*	5,700 ditto 21½ ditto	3 × 11
Vertical braces, *p p*	360 ditto 18¼ ditto	6 × 6
Bottom girders, *m m*	180 ditto 17¼ ditto	10 × 14
Bottom braces, *n n*	360 ditto 20 ditto	5 × 8
Support timbers (templates) *ii*	80 ditto 20 ditto	18 × 18
Pieces to nail on weather-boarding, *s' s'*	5,800 feet run	3 × 6
Weather-boarding, *s s*	95,000 feet super.	¾ × 12

PRACTICAL ILLUSTRATIONS OF THE METHOD OF INDICATING THE POWER EXERTED BY STEAM-ENGINES IN FACTORIES.

Sir,—In pursuance of this subject, perhaps I cannot do better than give detailed examples of cases in actual practice, as more likely to be of interest to practical men. With this view I have recently been furnished by a friend* with the annexed diagrams (Figs. 1 and 2),

Fig. 1.

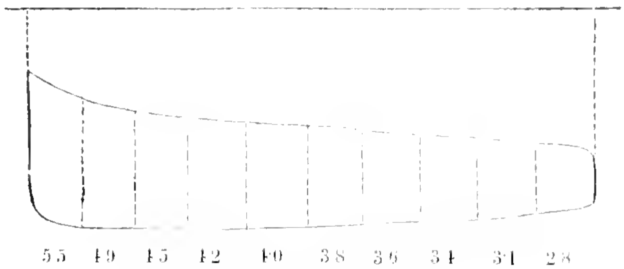


11.0 12.8 12.6 12.5 12.3 12.0 11.6 10.8 9.7 7.5

Average 11·28 lbs. per circular inch.

* A correspondent of your Journal, Mr. David W. Bowman, a young engineer of great promise, now on his way to South America.

Fig. 2.



Average 3·98 lbs. per circular inch.

together with an abridged extract from a report of an Indicator experiment made by him on one of Boulton and Watt's old 40 horse engines, now working in a cotton factory in Manchester, and also including some remarks thereon which seem pertinent to the subject of my last letter.

This engine has a cylinder 31½ inches diameter, 7 feet stroke, and a speed of 260 feet a minute. The diagrams were taken by Macnaught's Indicator, the scale of which is $\frac{1}{40}$ of an inch to each pound per square inch of pressure, or, which is the same thing, ·07854 of a pound per *circular* inch, the latter is the scale used, as it greatly abridges the calculation. Fig. 1 was taken when the whole of the machinery was at work in the usual way, and being measured, it gives an average for the gross pressure of 11·28 lbs. per circular inch. Fig. 2 was taken when the whole of the machinery was thrown off, the load of the engine then consisting only of the friction of the shafts, gearing, and straps running on the loose pulleys, together with the power required to work the engine itself. This figure, being measured, gives an average pressure of 3·98 lbs. per circular inch, for the friction of the engine, shafting, &c., which, deducted from the gross pressure, leaves 7·3 lbs. per circular inch for the net effective pressure.

The velocity of the piston, 260, drawn into the area of the cylinder, $31·5^2$, (=992·25 circular inches,) =257,985, and this number, divided by 33,000, gives 7·8 horse power, for each pound pressure per circular inch. This, again, multiplied by the nett effective pressure as above found (7·3 lbs.) gives nearly 57 for the "nett effective indicated horse power" then exerted by the engine.

The following remarks are extracted from Mr. B.'s report:—"The power consumed by the shafting unloaded seems enormous, but as there is an immense quantity of it, and a number of the steps, I am told, are not in very good order, and the straps, too, being probably very tight, I am inclined to think that the result given by the indicator diagram is not far from the truth. This result, which is usually called *available power*, means all the power that is exerted by the engine, exclusive of what is absorbed by the engine, shafts and straps; but it would be a mistake, however, to suppose that all this available power is delivered (so to speak) at the machine pulleys, for as the work is put on, the friction is increased through all the ramifications of the shafting, and the amount of this increase, which we have no means of ascertaining, must be deducted from what is called the available power, if we wish to know the amount of power consumed by the *machinery alone*. It is a good practice, however, to debit the machinery, not only with the power consumed by itself, but also with the power required to overcome the increase of friction along the shafting, and this I have done, calling them together available power. It is not a good term, and another wants substituting in its place. It is manifest, therefore, that a great quantity of shafting should be avoided, both on account of the power lost in turning the shafting itself, but also on account of the *increased increase* of friction when loaded."

The following is a list of the machinery, as furnished by the manager of the works:—

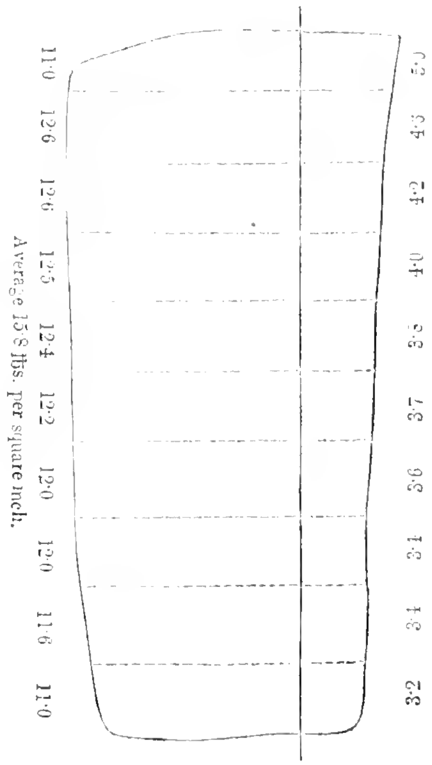
4 Pair of Mules, 648 spindles each.
1 Pair ditto 1080 ditto
8 Throstles 180 ditto
164 Calico Looms, 120 picks a minute.
60 Double Carding Engines, 50 inches each.
3 Drawing Frames, 14 rollers each.
6 Dyer's Frames.
1 Willow and Lap Machine.
Winding and Warping.
1 Mechanics Shop with Lathes and Grindstone.
63 Tape Looms, 25 pieces each.
11 Braiding Machines.
2 Tape Callenders.
1 Winding Machine.
2 Lathes and Grindstone.

Besides the above, there is a 9 inch pump 28 feet deep, which is included in the engine and shafting friction.

The remarks of Mr. Bowman bear evidence to the necessity of a nicer distinction in the technical terms used respecting the power of steam engines than has generally been admitted by engineers, and which necessity it was partly the object of my last letter to point out. The above list of machinery will also, I hope, be useful to mechanical engineers or others, who take an interest in the statistics of the steam engine. But I must observe that this engine must by no means be taken as an average specimen of the factory engines in Manchester; for as regards economy of steam, and consequently economy of fuel, it is considerably below that average. Indeed, I believe a worse case will not be easily found in any regular factory in Lancashire; and this is, in fact, one reason why I have selected it, for the serious consideration of those advocates of the expansive system who are continually boasting that the engines in Cornwall are doing five or six hundred per cent. more work for the same quantity of fuel than is done in any other part of the kingdom;* and also in order that there shall be no longer any mistake in this matter. Let any Cornish or other engineer point out clearly, how, even so little as 50 per cent. more work is to be done by the steam that the above engine uses, or a saving of one third of the fuel, and I know the owner of the engine will be very much obliged to him. I can find many factory owners that would be very glad to save even 10 per cent. in fuel at the present time, in addition, of course, to the ordinary interest of money for the capital required to be expended in adopting the improvement.

In the town of Manchester, owing to the difficulty of getting a sufficiency of cold water, the steam-engines are generally doing a much less duty than in the cotton-factory district surrounding it, where it is not uncommon to find them using about 6 pounds per horse per hour on the effective, or 9 lbs. on the nett effective indicated power. The diagram Fig. 3, which was sometime ago given me by my friend Mr.

Fig. 3.



* In a Cornish newspaper now before me (called "Lean's Engine Reporter and Advertiser,") for November, 1839, is inserted an extract from the Athenæum, in which it is stated "that *five* times as much work has been done by a Cornish steam-engine as by an *excellent* Boulton and Watt's engine on the common system; or that the same amount of work is done with one fifth part of the expense of fuel! A statement *almost* incredible, yet perfectly true." It is, indeed, "almost incredible" to me, that the respected authors of the Monthly Reports should allow such assertions to pass without note or comment.

Wright Elworth, of Preston, was taken by him from an engine belonging to Messrs. Horrockses, Miller and Co. of that town, working with about that rate of consumption. This engine is perhaps a fair average of the best engines in Lancashire, or such a one as might with propriety be compared to the average of those in Cornwall, whose duty is reported, in any question relating to the advantage and economy of the expansive system. I do not know the particular dimensions of this engine, but Mr. E informed me that it was then working at an effective indicated power of above 150 horses, which was about double its nominal power, as, indeed, appears evident from an inspection of the figure, which is measured by Macnaught's scale of $\frac{1}{10}$ of an inch for each lb. pressure per square inch, the vacuum averaging 11·39, and the steam 3·89, making a total gross pressure of nearly 16 lbs. per square inch. The temperature of the cold condensing water was 76°, and that of the hot well was 115°, at the time of the experiment.

I am, Sir, your obedient servant,

R. ARMSTRONG.

Manchester, 14th March, 1840.

IMPROVEMENTS IN BIRMINGHAM,

WITH AN ENGRAVING PLATE IX.

(From a Correspondent.)

Among many improvements which have lately taken place with reference to the public buildings of the town of Birmingham, are its magnificent Roman temple as a town hall, the grammer school, a splendid building in the Gothic style, the new churches, capacious market hall, railway stations, and several banking houses, all possessing architectural embellishments of no mean character, to these we may add Warwick house, the Drapery and Furnishing establishment of Mr. W. Holliday, just on the eve of completion, from the designs of Mr. W. Thomas, Architect. This building from its central situation in New-street its height, its extent of frontage, beauty of design and richness of detail may be justly entitled one of the ornaments of that improving town.

The annexed view is a perspective representation of the front as seen from the opposite side of the street. The design is in a style more than usually luxuriant, and the building occupies a frontage of 54ft 6in. in width and 5– ft in height; the whole pile covering an area of 5,77– ft. By reference to the engraving it will be seen that the shop front is divided into three compartments, by rusticated and empannelled elongated Doric pedestals or pilasters of stone supporting coupled lions on each, the size of life; they carry the enriched entablature of the shop front, the part over the lions breaks forward and is likewise in stone with enriched modillions. The sashes are of massive brass, glazed with plate glass, the squares are in one height in single plates, the dimensions of which in the centre division are 11ft. 2in. by 3ft. 2in. and to the side division 11ft. 2in. The upper part of the building above the shop front is also divided into three divisions consisting of a centre and two wings, at the angles of the latter are antæ or fluted pilasters, and in the centre division are two three quarter fluted columns of the composite order, the height of two stories, (the example from the baths of Diocletian at Rome,) supporting an enriched entablature. Above is a very richly decorated attic with enriched panelled pilasters semi circular headed windows, ornamented with carved masks, and shells, the whole surmounted by an open scroll parapet over the wings, and carved panels in relief, representing foliated Griffins, masks, and foliage in the centre, with pedestals and acroteria. The interior of the building is fitted up with a corresponding degree of richness. It is 104 feet in depth and divided into three shops, the centre is the principal department, fitted up in a splendid manner. It is divided into compartments by marbled Corinthian columns and pilasters supporting enriched entablature and ceiling, at the extreme end there are similar columns and pilasters with a centre plate of looking glass, 10ft. 1in. high by 3ft. 6in. To the left is the furnishing department and to the right is the French department, connected with which is a cloak room furnished with a looking glass, 8ft. by 6ft. and a painted glass window 9ft. 3in. by 8ft. representing Trade, Commerce, &c. The fixtures are of riga oak. The back part of the building is lighted by lantherns, glazed with plate glass, the basement is occupied with warehouses, and in the upper part of the building are the dwellings for the proprietor and the numerous establishment.

THE PATENT WATER ELEVATOR.

SIR,—I had a few days since an opportunity of examining a model of Hall's Patent Water Elevator, which appears calculated to overcome any difficulty in raising water to any required height at a very trifling cost; with the principle of it you are no doubt well acquainted, and I should not have troubled you with this letter but for a remark which a friend made on my naming the machine to him, he immediately recollected having seen some years since at Windsor Castle (as far as his memory serves him) what was then called "the Rope Pump," the only difference being that at Windsor a rope was used instead of a strap, from this it will appear that Mr. Hall is not entitled to any credit as an inventor, but merely for bringing before the public that which was probably only known to few individuals—In such a case is Mr. Hall's patent good? Or can any one use the rope without infringing on his patent?

I am, Mr. Editor,

Your faithful Friend,

AN ORIGINAL SUBSCRIBER.

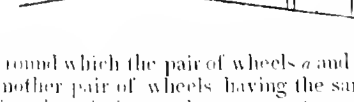
Leeds, March, 18, 1840.

*** We are decidedly of opinion that the use of the rope would not be an infringement of the patent. We are not very favorable to either the belt or the rope, as an economical mode of raising water. EDITOR.

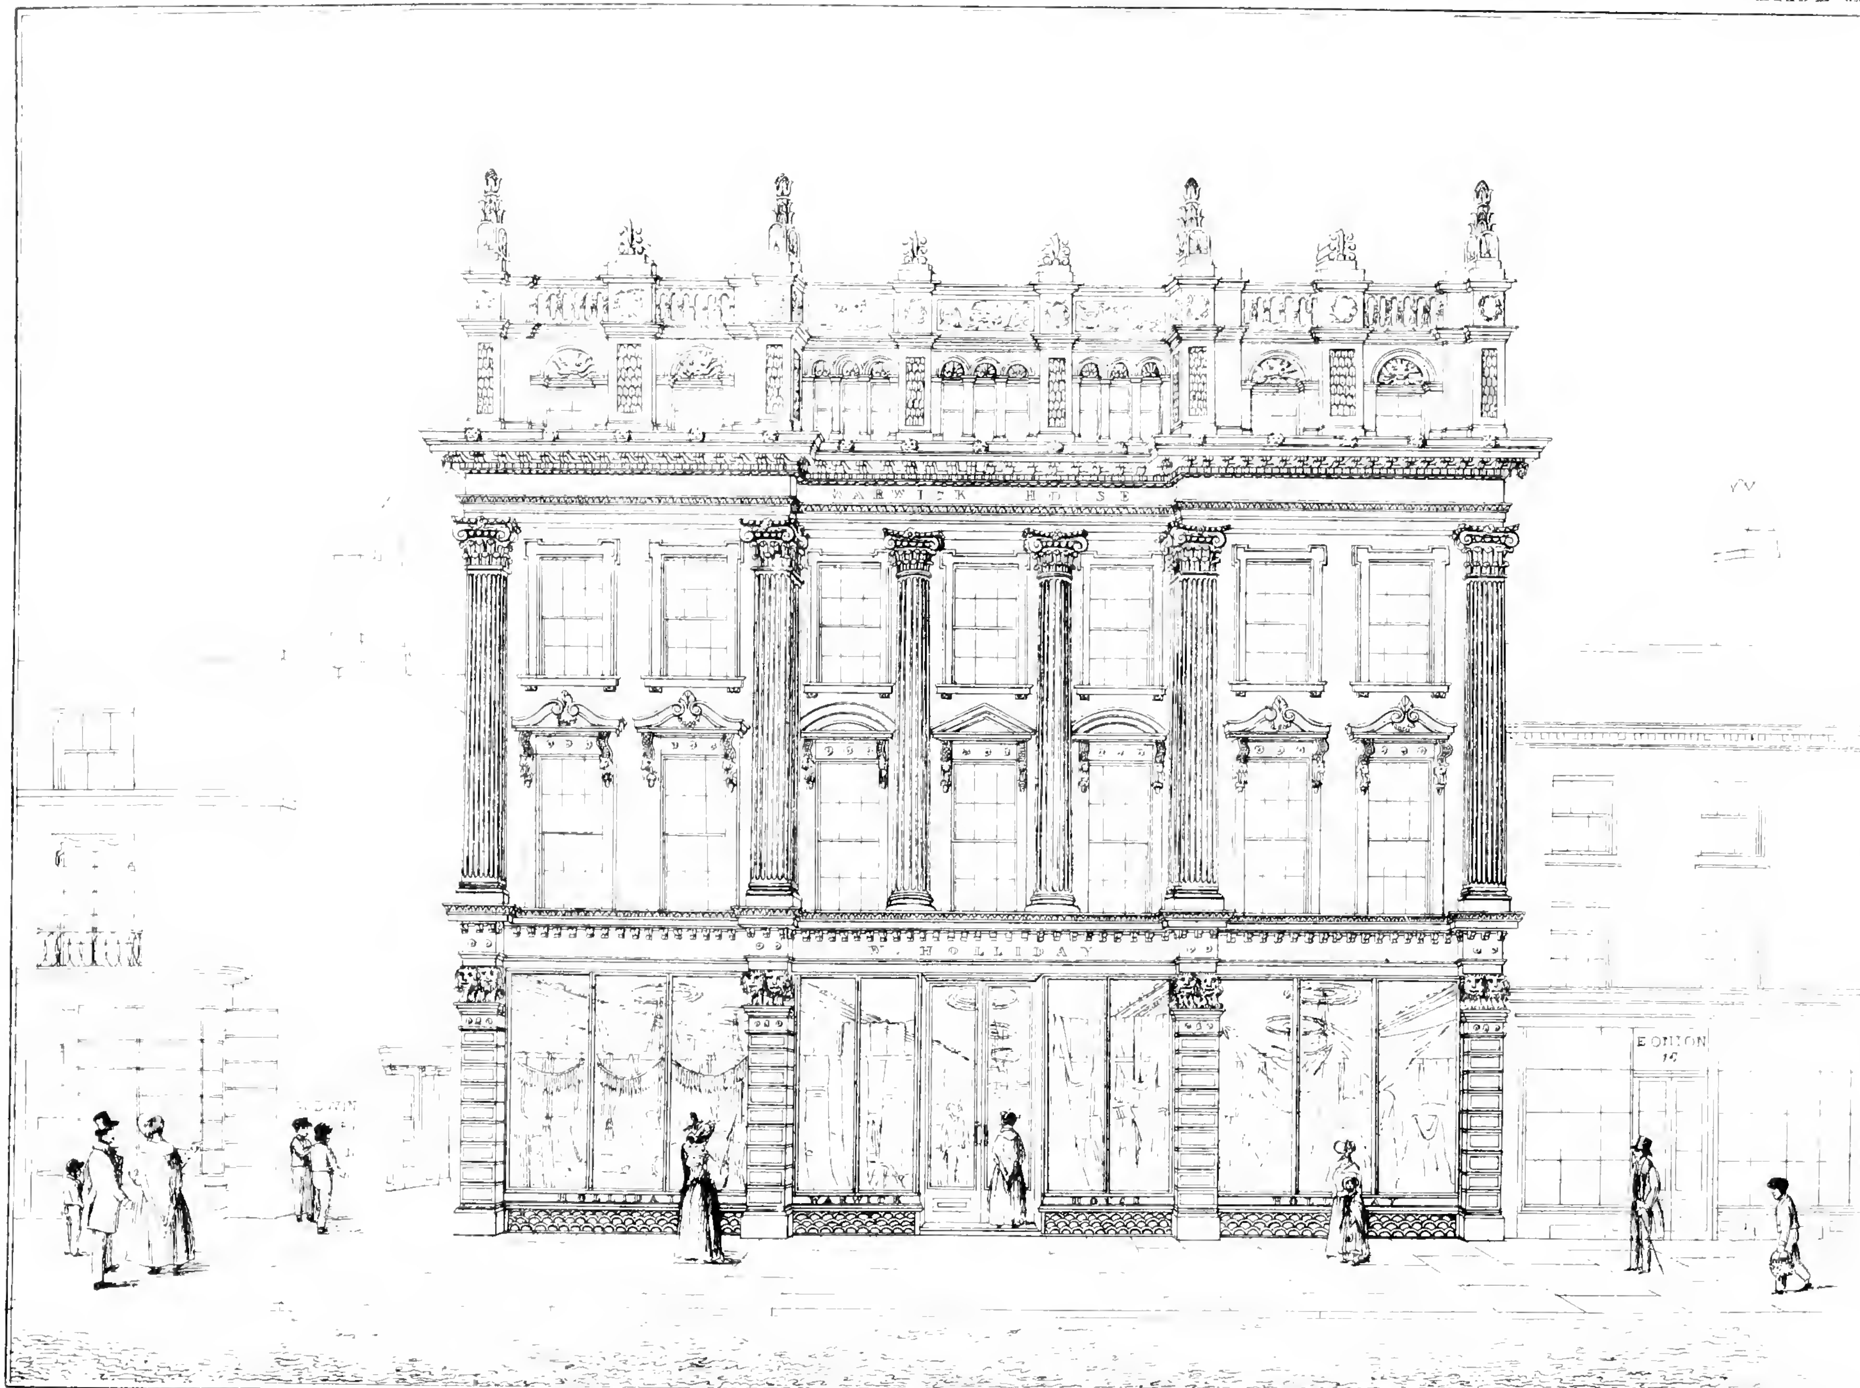
DR. LARDNER'S LECTURES ON RAILWAYS.

SIR—No doubt many of your readers have heard of the Lectures lately delivered at Liverpool and Manchester, by Dr. Lardner, "on the resistance to railway trains, the effects of gradients, and the general economy of steam power,"—he might have added a detailed statement of the profound ignorance of engineers on these points. Among other subjects he introduced that of conical wheels, and endeavoured to show that all engineers had fallen into an egregious error in supposing that the cone was of any service in enabling a carriage to move in a curvelinear direction, he said "never was there a more consummate mechanical blunder, the cone could do literary nothing; for they had left out of view the fact that the parallelism of the axles was preserved, and until they cease to be parallel the cone could do nothing. If a model carriage were constructed, with the wheels on one side small and on the other large, and the axles parallel, that carriage would not make so great a mechanical blunder as the engineers had done, &c."

Now, with all due deference, I must beg to dissent from the Doctor in his practical deductions; and I shall endeavour to show that the cone is practically the instrument by which carriages traverse curves. We know that if two wheels of unequal diameters be placed upon an axle and made to revolve, that the whole will describe a circle having for its centre that point where two lines drawn through the extremities of the diameters of the two wheels intersect thus.



c is the centre round which the pair of wheels a and b would revolve; and if there be another pair of wheels having the same relative proportions and their axle pointing to the same centre, and suppose these two pair of wheels to be connected by means of a carriage body, which would only slightly interfere with the conveyance of the axle, it is evident that the tendency of the wheels to move in the curve would exercise a force to preserve the condition necessary to do so; now my own impressions have always been that the tangential motion of the carriage would at first bring the outer wheel upon a diameter so much greater than the inner one, that its greater progression would exert a force sufficient to cause a deviation from parallelism in the axle which would suit the curve, the outer wheel will not slip unless the resistance to the axle assuming a convergence suitable to the curve, be about a $\frac{1}{4}$ of the insistent weight, which calling the weight of the carriage 5 tons would be $\frac{280}{4} = 70$ lb. on each journal or wheel. The curves used on railways are seldom less than 1 mile radius. If we call the distance between the axle 10 feet, which is more than they generally are, and taking the width of rails at 5 feet, we shall have the deviation from parallelism of the axles in order to point to the centre of the curve $\frac{10}{5280}$ ft. $\times$ 5ft. $= 0·11$ in. and as they revolve in four bushes, which bushes are con-



W Thomas Architect 1839

WARWICK HOUSE,

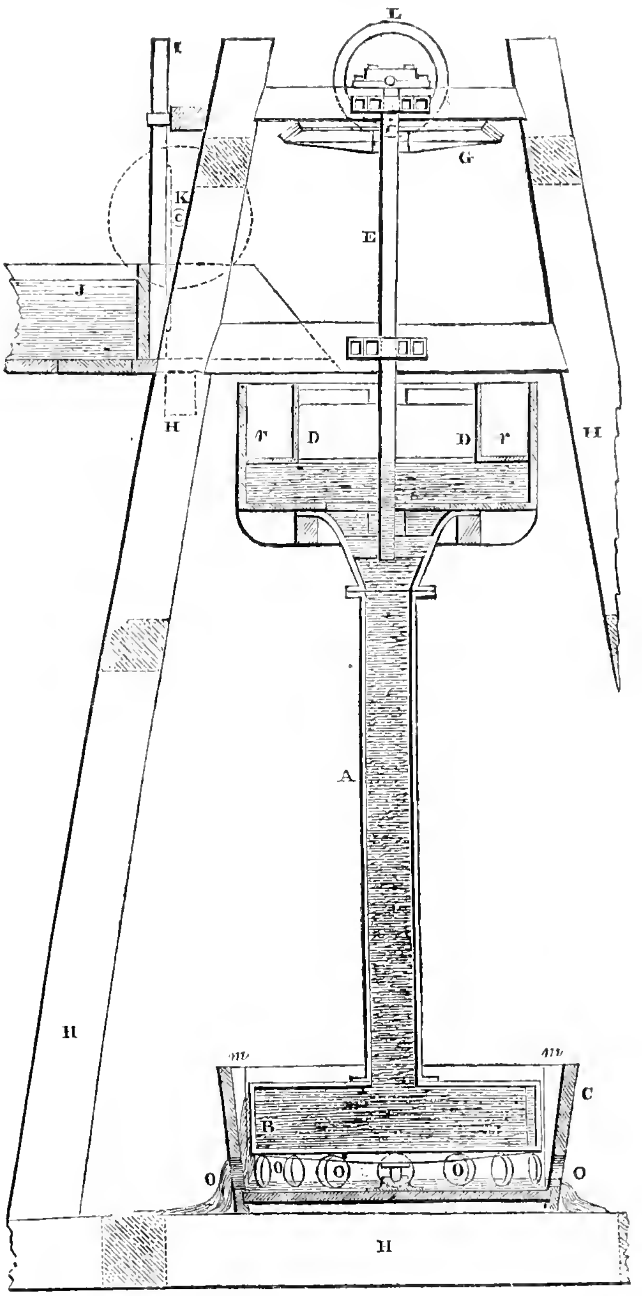
NEW STREET, BIRMINGHAM.

nected to the body of the carriage by means of springs, and kept in their places by guide plates, so that it is only necessary for the tendence to move in a curve to exert a force sufficient to alter the position of each journal, $\frac{11}{100}\times4=\frac{11}{400}$ of an inch, in order to pass round a curve a mile radius solely by the influence of the cone, a quantity so small that the Doctor will find great difficulty in persuading practical men that it is "*impossible*" such a deviation can take place, more especially as we see a force equal to 700lbs endeavouring to produce it.

INQUIRER.

VERTICAL WATER-WHEEL.

Fig. 1.—Elevation.



THE accompanying engravings represent a vertical water-wheel, upon the principle of Barker's mill, which I erected at the iron-works of the United Mexican Mining Association at Durango, in Mexico, in 1832, for the purpose of driving a circular saw; it was desirable to produce a rapid movement without the intervention of gearing, and this not being possible by means of the breast wheel, which was, besides, fully loaded with the blast machinery, it occurred to me to avail myself of Barker's mill; I first formed a rough working model, upon the usual construction, but found the action of it so very feeble, that I surrounded the arms with boards, in order that the flowing water might impinge against them; this arrangement quadrupled the velocity of the machine: I then added the upper part, which was a still further improvement. The height of fall was about 8 feet, the bore of the pipe about 12 inches, the length of the legs about 30 inches from the centre, the size of the orifices about $6\times2=12$ square inches, the velocity 40 revolutions a minute; by the period it was completed and set to work, the works were suspended, so that nothing further was done with it; I had an ulterior object in view in constructing this machine, viz. to devise some simple and efficient means of working the "tahonas," or grinding mills used in the reduction of the silver ore in the mining districts; this wheel would have been in these cases invaluable, as it was formed entirely of timber, excepting the step or shaft, and the few bolts and hoops with which the tube and legs were bound together; it would never have got out of order, and could not have been broken by any, but a wilful accident; any country carpenter could make it, and keep it going, and it required no heavy or large timber in its construction, for it can be supported as well by a wall, as the timber framing shown in the drawing.

FIGURE 1 is an elevation, the wheel and water-course shown in section. Fig. 2, a plan of the upper wheel, and Fig. 3, a plan partly shown in section of the legs and tube.

The same letters refer to each figure, so far as the parts are shown in each. A is the vertical pipe, mounted on the box B, forming the legs, the water issues from each extremity, and impinges with great force against the fixed floats *n*, *n*, &c., of the fixed tub *c*, and ultimately escapes through the holes *o* cut in the bottom of the tub. Upon the upper end of the pipe a cross frame is fixed, which carries the horizontal or upper wheel, which has furnished all round its in-

Fig. 2.—Plan of Upper Wheel.

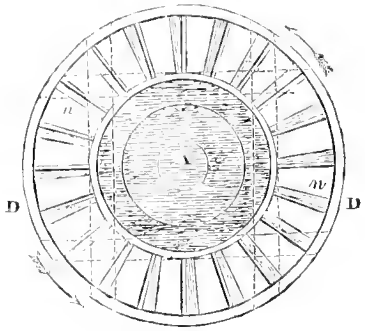


Fig. 3.—Plan partly shown in section.

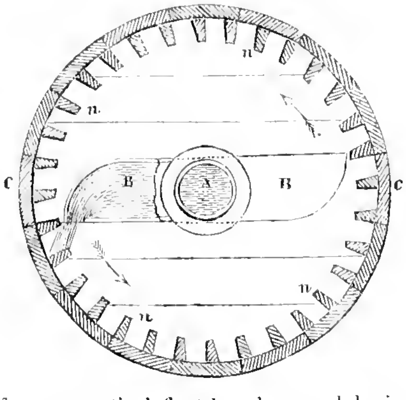

terior circumference vertical float-boards *r*, and horizontal floats *n*, which form cells, the water escaping into the tube through radiating openings left in the bottom as shown, thus advantage is taken of the momentum of the water rushing into the wheel. E is the vertical shaft, upon which the crown wheel G is hung, working the pinion L, which conveys the motion of the wheel, through the medium of its shaft, to the mill; J is the water and water channel, I the sluice, K the pinion to lift the sluice, H the framing by which the wheel is supported; the movement of the wheel is in the direction of the arrows shown in Fig. 2, and the reverse of those shown in Fig. 3.

15, *Stamford Street.* W. J. CURTIS.

COMPETITION DESIGNS.

Sir—Observing in your Journal of this month, a communication from Mr. Wyatt, which contains a correspondence between Messrs. Wyatt and Brandon and the Committee for building the proposed New Church at Cardiff, wherein my name is frequently introduced, I feel called upon in justice to my own professional character, to offer the following explanation, by which I think Messrs. W. and B. will be induced to view the circumstance in a different light to that in which they now regard it.

The first fact which I shall allude to, in order to remove any impression that may exist, as to my plan having been selected from personal preference, is, that I was an entire stranger to every one of the committee until after the adoption of my design had been determined on. Upon my enquiring (which I did at my first interview), how it was that the premium had been awarded to another, when my plan was considered the best, I was informed that the committee, anxious to do all in their power to insure justice to the several parties who had intrusted them with their designs, had submitted the several plans to two gentlemen in London, eminent in their profession, and that they had strongly recommended the adoption of my design, but considered I was not entitled to the premium, because I had not having, as *they thought*, acted in strict compliance with that portion of the advertisement which directed that the principal front should face Bute-street; and they concluded that this could not have been my intention, because the altar would not in that case have been at the east end of the church.

In this respect however my intentions were misunderstood, in consequence of my East Elevation having been described "Principal Front," instead of Front facing Bute-street, and in thus deviating from the usual custom of placing the Altar at the East-end, I considered I had sufficient precedent in the many Churches recently erected in which the Altar is not so placed.

Had this explanation taken place before the premium had been awarded, Messrs. W. and B. would have been spared the unpleasant correspondence they have had with the Committee on the subject, and I should in that case have received the premium, as well as the appointment of Architect to the Church.

Your insertion of this in your next Journal will oblige, Sir,

Your obedient Servant,

Thomas Foster.

4, *Park-street, Bristol, Feb.* 17, 1840.

*** This communication ought to have appeared in the last month's Journal, but it was accidentally omitted.—Editor.

REVIEWS.

On the Use of the Improved Papier Mâché in Furniture, in the Interior Decoration of Buildings, and in Works of Art. By Charles Frederick Bielefield.

This is not, as our readers might think, an exclusive catalogue of Mr. Bielefield's well known productions, but a large work containing engravings of above 500 approved ornaments used by architects, so as not only to be available for its special purpose, but useful to all members of the profession. As a work of reference or ornament this possesses the advantage that any design the architect may select, can be obtained at the shortest notice, while of these given in other works it generally happens that they cannot be obtained except at great cost for making models, &c. The architect can from these engravings select and combine a great variety of valuable specimens in every class of ornament.

Prefixed to the engravings is a history of the manufacture, to which we shall have occasion to refer in our next number.

Geometrical Propositions Demonstrated, or a Supplement to Euclid, being a Key to the Exercises appended to Euclid's Elements. By W. D. Cooley, A.B. London: Whittaker and Co., Ave Maria Lane, 1840.

The present is scarcely a supplement to the able edition of Euclid by Mr. Cooley, but a distinct work, intended to impress on the public the true value of geometry—its excellence as a method of reasoning and training the mind. The author well observes, that merely to read Euclid is not to become a mathematician, nor to attain all the advantages to be derived from geometrical studies, that we must not stop short, but carry out the methods of reasoning of which examples are afforded to us by that valuable work.

Guide to Ornamental Drawing and Design. By J. Page. London: Berger, 1840, Parts 1 and 2.

This work is one of the best and cheapest which has been written on the subject, and from the pen and pencil of a practical man, who has had the advantage of being able to see his instructions carried into effect under his own inspection, as Director of the Class of Ornamental Drawing, in the School of Design, at Saville House. If it were any recommendation to the work it might be mentioned that the illustrations proceed from the graver as well as from the pencil of Mr. Page.

The Year Book of Facts in Science and Art. By the Editor of the Arcana of Science. London: Tilt, 1840.

We are too large contributors from our own columns to this valuable record of the progress of science to view its improvement and success with any other feeling than that of congratulation. We sincerely recommend this work to our readers as one of the best condensations of valuable facts in science and art.

Claverton Hall.

This is an engraving of a building, built by George Vivian, Esq. on his property near Bath. It is in the Italian Villa style, and though not quite pure is a most interesting edifice. The outline is worked sufficiently without being frettered up, and has a most picturesque effect in harmony with the surrounding scenery. It is a good study.

Specimens of Wood Engravings. by Thomas Gilks.

Pleasing examples of this interesting art, and creditable to the talent of the engraver.

LITERARY INTELLIGENCE.

A new publication by Schinkel, entitled Werke der Baukunst, is about to appear in parts, at intervals of four months from each other, and will be more elaborately executed than his Entwürfe, as some of the plates will be printed in colours. Among the subjects promised are the designs for King Otho's palace, on the Acropolis at Athens which though not adopted,—the building now erecting being from one by Gärtner, of Munich, may be expected to prove of no ordinary interest, some parts of the interior having been spoken of as exceedingly striking, both for their originality and for their extraordinary richness, in regard to gilding and colouring. This subject will be illustrated by twelve plates, some of which will probably contain two or three drawings. Another subject mentioned in the prospectus is prince Albert of Prussia's palace, or villa of Camenz in Silesia. The size of the plates will be 26 inches by 15. Another German work announced for publication is Ehrenburgh's Bau Lexicon, or Dictionary of Architectural terms, &c., of which we shall be able to speak more at length in a short time.

SIR JEFFRY WYATVILLE, R.A.

The subjoined memoir we have derived from Fisher's National Portrait Gallery, the Literary World, Art Union, Athenaeum, &c.

Sir Jeffry Wyatville, Knight of the Saxon Ernestine Order, R.A., F.R.S., and F.S.A., was the son of Joseph Wyatt, an architect, resident at Burton-upon Trent, in the county of Stafford, where he was born on the 3rd of August, 1766. His father was considered clever, but indolent, and, therefore, afforded but a poor example for a boy of enthusiastic and enterprising spirit, such as young Jeffry soon proved himself to possess. He received the common rudiments of education at the free-school of his native place; and his early passion was for the sea. During this time, he was once "rigged out" for a voyage with Admiral Kempenfeldt, on board the *Royal George*, but was fortunately prevented from joining that noble ship, which was afterwards lost at Spithead. Home, however, became not only irksome, but painful, to him, from the improvidence of his father; and, in 1783, he made a third and succesful attempt to fly from both, and seek his fortune in the metropolis; but could not obtain any engagement in the naval service, as the American war had then ceased.

Upon young Jeffry's arrival in London, he found a friend and protector in Samuel Wyatt, his father's brother, then an architect and builder of repute; with whom Jeffry continued more than seven years, and thus acquired considerable knowledge of the ordinary office business, and of practical construction. Mr. S. Wyatt was extensively employed, both in London and at the seats of many noblemen and gentlemen in the country, namely, at Eaton Hall, Tatton Hall, the Trinity House, London, &c., all of which were executed from his designs; and, consequently, afforded his nephew opportunities of witnessing all the processes of designing, estimating, and executing, buildings of various kinds. In the hope of acquiring further professional knowledge, and particularly with a view of cultivating that essential requisite in art, taste, young Wyatt sought these advantages in the offices of another uncle, Mr. James Wyatt, who had attained a higher station on the ladder of fame than his brother. He had passed some years of architectural study in Italy, and, while yet a minor, he designed and built "the Pantheon," in Oxford-street, and was introduced to the appointment of Surveyor-General of his Majesty's works, his first labours being various alterations and additions at Windsor Castle, at the suggestion of King George III. In the office of Mr. James Wyatt, his nephew served a second term of apprenticeship; and, besides improvement in practice, thus obtained numerous introductions to influential persons, among whom was the Prince of Wales, who honoured him with personal notice up to 1799. In this year, Mr. Jeffry Wyatt joined in business an eminent builder, who had extensive government and other contracts. In this profitable concern he continued till 1824: when, after an absence of twenty-five years from Royal intercourse, he unexpectedly received from King George IV. instructions respecting designs for the restoration of Windsor Castle.

The union of the tradesman with the architect was deemed, by the Royal Academicians, a sufficient bar to the advancement of Mr. Jeffry Wyatt to be one of their society; and he was allowed to continue as a candidate for twenty years, before he was admitted a member. During this period, he made many designs for public and private buildings, which were erected in different parts of the kingdom, some of which manifested architectural talents of a high order. He was, at length, elected an associate, and speedily afterwards, one of the Royal Academicians. Among various designs which he had exhibited at that nursery of the arts, was one called "Priam's Palace," which attracted much admiration during the exhibition. This, and his other architectural drawings, and executed buildings, are ample evidences of his love of, and devotion to, his profession.

One of the first acts of the new Parliament, after the accession of George IV., was the projection of great alterations and improvements in the magnificent castle-palace at Windsor. For this purpose, it was agreed that the three attached architects to the Board of Works, Messrs. Soane, Nash, and Smirke, with Mr. Jeffry Wyatt, should be directed to make plans, drawings, and estimates. The sum of £300,000 had been voted by Parliament towards the expenses of these improvements, and a committee of eight noblemen and gentlemen, members of the administration and of the opposition, were appointed to advise as to the work and expenditure of the money. Among these "Commissioners" were the Earl of Aberdeen, President of the Society of Antiquaries, and Sir Charles Long, (subsequently Lord Farnborough,) a distinguished Fellow of that enlightened institution; both men of refined taste in the higher departments of art. In May, 1824, the respective architects above named (with the exception of Mr. Soane,) submitted their drawings to the Commissioners, when the designs of Mr. Jeffry Wyatt were approved of, and accepted. The Commissioners next visited Windsor; the plan of operations was settled, and, on the 12th of August, 1824, the birthday of George IV., the first stone was laid by the King, it being part of the foundation of the new gateway on the southern side of the Great Quadrangle, and thenceforth named George the Fourth's Gateway. On this occasion, the architect received the royal authority for changing his name to Wyattville; not merely as a personal compliment, but for the purpose of distinguishing and separating the Wyatt of that reign from his uncle, Mr. James Wyatt, whose share in the architectural works at Windsor, during the reign of George III., has already been mentioned. Furthermore, George IV. suggested and conferred the additional armorial quartering to the architect's family arms, of a view of George the Fourth's Gateway, with the word *Windsor*, as a motto.

Without the aid of plans and views of the buildings, it is impossible to convey to the reader any clear idea of Windsor Castle at the time that Mr. Wyatville commenced his improvements, in 1824, and at the period of their recent completion. It may be sufficient to mention, that the alterations and additions made in the Castle buildings, from the commencement of the Tudor dynasty to the year 1824, were not only inharmonious with the castellated character of the older works, but were generally tasteless in design, and slight and bad in execution. Hence the whole of the latter class were taken down, when the whole of the main timbers were found to be decayed. New floors and ceilings, with new partition walls, were necessary; and to improve the exterior effect of the elevations, each wall was raised several feet, and finished with bold embattled parapets. The angular and intermediate towers were also augmented in height, and each crowned with a machicolated summit. The chimney-shafts were formed into stone clusters, and made to assume the shapes of turrets. Around the south and east sides of the interior of the great quadrangle, was erected a spacious corridor, 550 feet in length, connected with and forming grand and convenient approaches to the chief suites of apartments which belong to those parts of the Castle.

The works proceeded with such rapidity, (the architect devoting the whole of his time to the vast undertaking,) that, on the 9th of December, 1828, the King's private apartments were completed, and His Majesty removed from his rural retreat, a superbly embellished cottage in the Great Park, and formally took possession of the Castle. The next public act of the King was to confer the honour of knighthood on his architect, who, also, was permitted to take up his residence in a commanding tower, in the middle ward, at the west end of the north terrace.

The progress of the repairs was rather expedited than stayed by the King having taken up his residence at the Castle. The decayed and dangerous state of the building had, however, occasioned an expenditure much beyond the original estimates; indeed, at Midsummer, 1830, the cost appeared to have been nearly doubled.

Application was, accordingly, made to Parliament for further advances; when, opposition being raised in the House of Commons, a committee was appointed to investigate the Castle works, and the probable amount of money requisite for their completion. The committee, at length, ordered works to be undertaken to the estimated amount of £148,796, to be advanced at the rate of £50,000 per annum. This grant was made exclusively for the architect's department, independent of the upholsterer, decorator, and other artisans. Since that time, much has been done. The Elizabethan Gallery has been finished, and fitted up as a library; the Waterloo Gallery has been completed, and adorned with portraits, by Lawrence, of the principal monarchs, statesmen, and generals of Europe; the old principal staircase has been removed, so as to present an uninterrupted view from the northern terrace, *through the superb pile* by means of opposite entrances, to the unrivalled Long Walk on the south; a noble staircase having been elsewhere constructed, in which is placed a colossal statue of George IV., nine feet, six inches high, by Chantrey. Lodges have also been erected at the junction of the Long Walk with the Home Park; and several of the old state apartments, at the north-west part of the upper court, have been enlarged and substantially repaired. At the north-west angle of this court, Sir Jeffry had designed a splendid chapel. The heightening of the Keep, or Round Tower, by some feet, is also an important feature which adds pre-eminently to the dignity of the magnificent pile.

It has been well said, "so completely has Sir Jeffry made the Castle his own, that nobody can distinguish between what belongs to himself and his predecessors." ... the building is old, while the material is new; and the harmony of parts is so complete as to form a whole of almost inexpressible magnificence and grandeur.

Von Raumer, on his visit to England, found Windsor far exceeding his expectations, and making a greater impression on him than all the other castles he had ever seen, put together. "This is high praise," says the Literary World, "from a native of Germany, where feudalism has left so many stately monuments of its frowning glory."

Hitherto, there has been published no fitting record of this grand national repair of the proudest structure that England possesses. King George IV., with the intention of consummating the truly regal labour, and, in strict princely state, commanded Sir Jeffry Wyatville to publish an account of his great work; the missive, in the handwriting of the sovereign, is in the possession of Sir Jeffry's executors, as is also a confirmation of the command, from Queen Victoria. Sir Jeffry had made much progress in his task; he having expended £5000 upon drawings.* In the Picturesque Annual, the author relates, that George IV. promised to send a copy of Sir Jeffry's work to every sovereign in Europe; but, with the exception of this patronage, Sir Jeffry, it is believed, although working at the Royal command, did not expect assistance of any kind. On one occasion, when surprise was expressed at such a condition, Sir Jeffry replied, in the spirit and pride of art; "The task is MINE; I am preparing my own monument."

Notwithstanding that Windsor Castle is the *chef d'œuvre* of Sir Jeffry Wyatville, and, for ages to come, will stand as the best record of his skilful taste, he had wholly built, or improved, many other edifices in different parts of the kingdom. He has left some of his works in thirty-five, out of the forty, English counties, and four, out of the twelve, Welsh. From a list of above 100 of these buildings, the following, with the names of their owners, are appended to the memoir already quoted:—

Badminton House, Gloucestershire, Duke of Beaufort.—Drawing-room and library.

Woburn Abbey, Bedfordshire, Duke of Bedford.—Temple of the Graces.

At Endsleigh, Devonshire, Duke of Bedford.—A spacious and commodious seat, in the cottage style.

Chatsworth House, Derbyshire, Duke of Devonshire. Some magnificent new buildings, also alterations and restorations of the old mansion, in the Italian style. These have just been completed.

Longleat House, Wiltshire, Marquis of Bath.—New conservatory, stables, offices, staircase, and alterations of the hall, &c.

Ashridge, Hertfordshire, Earl of Bridgewater.—The completion of the house, begun by James Wyatt, R.A.; the Bridgewater column in the park, and lodges.

Bretbey, Derbyshire, Earl of Chesterfield.—Parts of the house.

Gopsall, Staffordshire, Earl Howe.—A new lodge, &c.

Belton House, Lincolnshire, Earl Brownlow.—New green-house, and alterations to the mansion.

Wollaton Hall, Nottinghamshire, the Lord Middleton.—Alterations to the interior, and new lodges to that fine Italian house.

Sidney College, Cambridge.—New gate-house, and fronts to the whole college.

Besides the above, which are generally called show places, Sir Jeffry has designed and executed the following *new houses*:

Lilleshall, Shropshire, Earl Gower.
Golden Grove, Caermarthenshire, Earl of Cawdor.
Nonsuch Park, Surrey, Samuel Farmer, Esq.
Dinton, Wiltshire, William Windham, Esq.
Denford, Berkshire, William Hallett, Esq.
Stubton, Lincolnshire, Sir Robert Heron, Bart.
Hillfield Lodge, Herefordshire, The Honourable G. Villiers.
Trebursye, Cornwall, The Honourable William Elliot.
Banner Cross, Yorkshire, General Murray.
Wimborn, Dorsetshire, William Castleman, Esq.
Claverton, Somersetshire, John Vivian, Esq.
Hastings, Sussex, Compt de Vandes, &c. &c.

By the introduction of Queen Adelaide, Sir Jeffry designed a castle for Altenstein, for her brother the reigning Duke of Saxe Meiningen; as also a palace, with extensive stables, and a riding house for Meiningen; for which works the Duke presented him the grand cross of the Saxon Ernestine order, as a mark of his approbation. In the summer of last year he designed the stables at Windsor Castle. This design, though of almost quaker like plainness, evinces the same strong faculty for arrangement under difficult circumstances, which characterized all his former works. As late as November last, he designed lodges for the Sheffield and Derby entrances to Chatsworth: the latter of which is full of boldness and originality, and as vigorous as any design he ever produced, although his last work, except an Alcove for the gardens, which is as playful as the work of a young hand.

* Mr. Weale has received instructions to publish this splendid work forthwith.

Sir Jeffry Wyatville was proud of the Royal patronage which he enjoyed; and the Sovereign was alike proud of his favorite architect. As a compliment, a portrait of him was painted by Sir Thomas Lawrence, by command of George IV., and was placed in the royal collection at Windsor Castle. It is considered to be, altogether, an impressive likeness: there is extraordinary quickness in the eye, and the forehead is lofty, but wants breadth, such as indicates superior intellect. We believe Sir Jeffry to have been in no degree indebted for his success to sycophancy; for, although "of the court" he was not over courteous in manner. His roughness, however, enabled him to conquer the caprice of his royal patron. It is related in the *Athenæum*, that "when the kings private apartments were under consideration, his Majesty was naturally somewhat more peremptory than usual, especially as to their relative proportions, and it is well known that he did not like large rooms. Wyatt's head, however, was full of a palace; and when the king suggested what he considered a proper size for his dressing room, Wyatt protested that such a cupboard was better suited to a country curate than to his Majesty. The latter, however, was peremptory on the subject, and cut short all remonstrance with—" It shall be so." The works went on—the suite of apartments was finished and furnished, when, in the exultation of the moment, his Majesty good-humouredly reminded the architect of their former difference, and triumphantly referred to the admirable adaptation of this particular chamber. 'I am glad your Majesty approves of it,' said the architect, 'for it is exactly twice the size your Majesty directed."

He languished for the last five years, under a disease of the chest, which has visited him with voilent attacks from time to time; and frequently endangered his life. Still his mind never gave way, or was weakened by illness. He possessed the same good sense, industry, and indefatigable order in his art during his last illness, as at any former period of his career—which was marked by simplicity and integrity, as was his death by perfect cheerfulness and resignation. His last days were a dignified lesson to the old, as his well spent life had been a model of usefulness to the young. He died on the 18th of February, in his 74th year.

The remains of Sir Jeffry Wyatville were interred in St. George's Chapel, Windsor, on the 25th ult.; the body having arrived at the Winchester or Wyatville Tower, on the preceding evening. The Rev. Dr, Goodall, Provost of Eton, an old and valued friend of the deceased, read the burial service; and the coffin was deposited in a vault in the east aisle of the Chapel, just behind the altar; which Sir Jeffry had prepared some years since, for the reception of the remains of his daughter, who, it is stated, died in consequence of a cold, taken during her attendance at the ceremony of laying the foundation stone of theBrunswick Tower. Among the mourners was Sir Francis Chantrey, the sculptor. And thus, within the shadow of the stately pile which his genius had restored from crumbling decay, sleeps the architect himself; thus exemplifying the adage: "Art is long, and life is but short."

NOTES OF THE MONTH.

The Oxford Society for the Study of Gothic Architecture is making progress, its library is increasing, and the papers read at its meetings have been valuable and interesting. It is to the clergy that we must look for the preservation of old edifices, and for the observance of good taste in the erection of new ones.

Mr. Cockerell has been selected to erect the new Institute at Oxford, founded by the late Michael Angelo Taylor.

The second of this month is the day on which the tenders are to be sent in for construction of the Nelson Memorial. The shaft is to be solid, of granite from the West of England, and the capital of bronze.

Messrs. Grissell and Peto have commenced operations for raising the superstructure of the New Houses of Parliament.

The Royal Exchange affair is still in statu quo, except that as far as report goes Mr. Cockerell and Mr. Tite are engaged in making fresh plans. We doubt much whether they will be able to produce a better design than that of Mr. Donaldson, which we had another opportunity of viewing, when it was exhibited at the Royal Institute of British Architects. If, as Mr. Smith reported, at maximum prices it only exceeded the sum allotted by £9000, it ought to be adopted. As to the paltry objection that there were no chimneys, any man with brains in his head might have seen that they could have been introduced in any part of the walls which surround the room, the thickness of which was ample for flues, but the system of warming public offices by hot water or steam is so general that it could hardly be thought necessary to provide fire-places. Then again as to the statement that many walls had false bearings, even if such had been the case, this might easily have been remedied without in any way interfering with the external design, which is the grand feature to be considered. As to the last objection, that there were not sufficient shops, it is too contemptible to require notice.

Another competition exhibition takes place this month, that on the 8th for laying out the grounds of the Royal Botanic Society. We hear that many designs of merit are in preparation, and we sincerely trust that the Council will allow a public day for the profession to witness an exhibition, which we believe has never before taken place in the metropolis.

On the first (anomalous day!) the Soane Museum opens to the public! When will this Museum and Library of Architecture be made what it ought to be?

The Institute of Architects of Ireland has received the Royal patronage, and we sincerely trust that the institution will be worthy of a capital possessing so many fine buildings.

A new shop in the style of the Revival is now attracting attention in Regent-street, being the first in this fashionable style.

Some Elizabethan pumps a little above the common run have been erected in Holborn and its vicinity.

The wood pavement in the Strand is on Parkin's plan.

Iron statues are in great vogue at Paris as accessories for architectural purposes.

The embankment of the Thames is at last likely to be taken up by governvernment and city authorities.

We feel great pleasure in announcing that a want severely felt by artists, that of a gallery of casts is at last to be remedied, not by government, but by private enterprise. A similar plan was stopped last year in expectation of the government doing something, but it was so absurd that it was fortunate it was abandoned, being neither more nor less than to interfere with private enterprise, by manufacturing all kinds of casts. A worthy companion to the steam boat plan! Mr. Braham, with great public spirit, has opened the Model Gallery at the Colosseum as a place for study at the trifling subscription of one guinea per annum. It is well lighted, and contains above a hundred works, including the Tragic Muse (12 feet high), Apollo, Townley Venus, head of Achilles, Moses of Michael Angelo, &c.

There is an intention on the part of government to make a grant to the Schools of Design. This would be a boon to the manufacturing interests and the fine arts generally.

A statue to Napier, the inventor of logarithms is in agitation at Edinburgh.

At the Institute of Civil Engineers Mr. Nasmyth exhibited his pneumatic mirror, which is a plate of glass 3 feet in diameter, on a concave disc of iron hermetically sealed. On exhausting the air the plate collapses, and on its being forced in the plate rises so as produce any form of speculum. Mr. Nasmyth suggests its application to astronomical purposes for large reflecting telescopes, or it may be used as a burning glass.

Mr. Whishaw the engineer kindly exhibited to us a valuable chronometer which he has used in preparing for his elaborate work on Railway Statistics, for ascertaining the velocities of railway trains. It is 3 inches in diameter, and consequently of a circumference of near $9\frac{1}{2}$ inches, which is a scale of one minute decimally divided into hundredths, so as to enable nice calculations to be made with accuracy.

In the valuable paper of Mr. Leeds in our present number, we took the trouble to note down the length of life of 142 architects enumerated, and found one-third between 65 and 75, of which 27 between 70 and 74, and 22 between 75 and 80. A pretty good proof of the longevity of this class of professional men.

We have not had the opportunity of mentioning before the completion of the lighthouse on the sands at Fleetwood on Wyre. This is constructed by Mr. Mitchell with his patent mooring screws, on a similar principle to that on the Maplin sands described in the Journal. It is of an hexagonal form, six mooring screws supporting the base with one in the centre thus,

o o
o o o
o o

These carry converging posts on which the platform is erected, which carries the lighthouse, so that it is open below to the action of the sea. This work, in an incomplete state, stood out the late severe gales, and does great credit to its constructor, and to the spirit of Sir Hesketh Fleetwood.

A BILINGUAL STONE.

A bilingual inscription, containing Latin, Umbrian, or Etruscan words sculptured on both sides of a Tiburtine stone, was found some months ago near the ancient ruins called Mausoleo. At first it was believed to be apocraphal; but on being brought to Rome and examined, all doubts with regard to its authenticity were removed. From the Latin words *Frater eies minimus,* which occur in the beginning, it was hoped that something of interest might be deduced. The rest of the inscription can only give room for conjecture, the letters running from left to right, as is evident from the expressions, *Locavit et statuit*, which in themselves contribute in no way to elucidate the obscurity of the Epigraph, and it is well known that the national paliography whether Umbrian or Etruscan should run from right to left. This stone was in all probability a terminal *Cippus*, referring to the period when the Romans made Etrusia a subjected province, as yet, however, the true and precise signification is obscure, first on account of its bilinguous form, and also for the uncertainty of the letter X which is known to be a T in Umbrian or Etruscan. Another ambiguity arises from not knowing the true pronunciation of K and ⊳⊲. This however must be left to the consideration of the learned, and for whose better judgment we subjoin the following copy of the epigraph.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

SESSION, 1840.

Jan. 14. JOSHUA FIELD, V.P., in the Chair.

"*Observations on the efficiency or gross power of Steam exerted on the piston in relation to the reported duty of Steam Engines in Cornwall, at different periods.*" By JOHN SCOTT ENYS, Assoc. Inst. C. E.

The advantages which may result from the union of scientific and practical knowledge in the application of steam power, particularly with reference to the limits of gross power, are great, as likely to check the extravagant notions entertained by some with respect to the farther increase of duty, and to remove the disbelief of others with respect to the amount of duty actually performed.

The limit of duty for atmospheric steam may be readily arrived at, as was done by Mr. Davies Gilbert in 1827, by estimating the weight of water which would rise 34 feet into a vacuum formed by the condensation of steam of atmospheric strength; whence it appears, that a higher duty than 30 millions cannot be obtained by atmospheric steam, 14 cubic feet of water being evaporated by a bushel of coal. Tredgold, in the first edition of his Treatise on the Steam Engine, published in 1827, adopted the simpler method of multiplying the volume of steam of atmospheric strength by the pressure, for the measure of the efficiency. This principle may be extended to measure the efficiency of steam at higher pressures, as the author has shown in the first annual report of the Cornwall Polytechnic Society; and an extended table to ten atmospheres is appended to this communication.

The author then proceeds to show, that the Cornish engines are worked under conditions such that a large proportion of the expansive action of the steam is available on the piston, and calls attention to two necessary corrections—1st, for the deficiency of water in high steam cut off at $\frac{1}{4}$th of the stroke; and 2d, for the increase of temperature of the steam during expansion in the cylinder, as derived from the steam jacket. The experiments of Mr. Wicksteed, confirmatory as they are of the very extended experiments made by Woolf at Wheal Alford, show the importance of this latter correction. Some error has also arisen from the use of the boiler pressure. The exact determination of the pressure in the cylinder is difficult, and the only recorded experiments are those by Mr. Henwood with the common indicator, and published in the second volume of the Transactions of the Institution. The indicator is liable to show a pressure higher than that actually exerted during the expansion, but it may be relied on for comparative results; and very accurate experiments made at the Consols by a mercury gauge, the engine being stopped at differents parts of the stroke, are said to confirm the reliance which may be placed on the indicator.

The quantity of water evaporated was very imperfectly recorded; it was stated by Watt as from 8 to 12 cubic feet per bushel, and at present may be stated at about 14 cubic feet, but is sometimes, with good coal and careful stoking, much higher.

The author briefly alludes to the progress of improvement in Cornwall; the introduction by Woolf of high steam; the substitution of the plunger pole for the bucket pump, and the application, so recently made by Mr. James Sims, to stamping or crank engines of the arrangements which had been a long time so advantageously in use in pumping engines.

The communication is accompanied by a table, exhibiting the weight of water per cubic foot; the pressure; the volume and the efficiency of steam from one to ten atmospheres, adapted and corrected from those of Clement and Desormes. It is also accompanied by a method of representing several particulars connected with the load and engine; by which the relation of these with respect to each other in the same engine, and the different conditions of other engines, may be at once exhibited to the eye. It may also prove a convenient method of recording facts and calculations in connexion with the Indicator Diagrams.

"*Analysis of a piece of the iron heel post converted by the action of Sea Water into a substance resembling Plumbago.*" By DAVID MUSHET, A. Inst. C. E.

A piece of the iron heel post of a vessel called the John Bull had been presented last Session by Mr. Borthwick, as a curious specimen of the effect of salt water in converting iron into a substance resembling plumbago. This substance was of a dark brown colour, and easily cut by a knife, and Mr. Mushet undertook to analyse it; and the result of this analysis, and the methods pursued, are the subject of this communication. This substance, which it may be convenient to call marine plumbago, on being exposed to a red heat in a crucible, lost about 20 per cent. in weight, and on being exposed to a white heat for four hours lost about 60 per cent., and came out a light mass of very brilliant carburet. This shining carburet was then used as a carbonaceous substance for the reduction of an oxyde of iron, but was less efficacious than the same quantity of the charcoal of wood. From these and other experiments, Mr. Mushet considers 100 parts of the so-called marine plumbago to be composed near as follows:—

Carbonic acid and moisture	20
Protoxyde of iron	35·7
Silt, or earthy matter	7·2
Carbon	41·1

Also, he considers 100 parts of the common black lead to consist as follows.

Carbonic acid and water	12·5
Iron	11·5
Earthy matter	4·5
Carbon	71·3

"*A theoretical calculation of the Fuel saved by working Steam expansively.*" By J. W. LUBBOCK, Hon. M. Inst. C. E. &c. &c.

An equation may be readily formed for the action till the steam is cut off; and the steam being then supposed to dilate into a certain volume, the variation in this volume gives rise to the quantity of action, whence another equation may be obtained, and the maximum of the quantity of action produced by cutting off the steam determined. The quantity of action thus produced is then compared with that produced in any case without cutting off the steam. Now the quantity of heat or fuel expended is proportional to the steam generated in each of the preceding cases, and a proportion, expressing the ratio of the fuel saved to the fuel expended, may be obtained.

"*On the Expansion of Arches.*" By GEORGE RENNIE, F.R.S.

The expansion of solids, which has excited the attention of mathematicians since the investigation of La Hire, in 1688, on a rod of iron, is of particular importance in the construction of bridges, the security of which may be effected by the dilatation and contraction consequent on changes of temperature. Periodical motions, referable only to changes of temperature, were observed by Vicat in a stone bridge built over the Dordogne at Souillac, and have frequently been noticed in structures of all kinds. The different expansibility of stone and iron has been considered an objection to the use of cast iron pillars in connexion with stone to support the fronts of buildings; but the experiments of Mr. Adie of Edinburgh led him to the conclusion, that no danger is to be apprehended from a change of temperature affecting cast iron and sandstone in any great degree, as their expansion, so far as regards buildings, may be considered the same.

Arguments from this source were employed against the arches of Southwark Bridge, and the experiments set forth in this communication were undertaken with a view of ascertaining the effect of temperature on these arches.

Three sets of experiments were made: the first in Jan. 1818, when the main ribs and diagonal braces rested on their centres, and before any of the spandrils and road plates had been put upon them; the second, in the August and September of the same year. The rise was measured by the insertion of small wedges to about $\frac{1}{40}$th of an inch. The third set of experiments was made on the eastern arch. Three thermometers were employed—one hanging in the open air, another having the bulb immersed $1\frac{1}{2}$ inch in the iron, and the third hanging amongst the ribs; these were observed at different hours of the day, and the results recorded. The rise of the arch was observed by a fine piece of feathered edged brass, nicely fixed to the rib, which by the rise and fall of the arch traversed upon a scale graduated to $\frac{1}{80}$th of an inch. The tables contain experiments on nine days, with the temperatures and rise at every hour of the day. The results, that is, the maximum temperatures and rise, and rise for 1° Fahr. are exhibited in the following table.

No. of Experiment.	Variation in Temperature.	Rise in Arch.	Rise for 1° F.
I.	15°	$\frac{25}{80}$	$\frac{1}{48}$
II.	10°	$\frac{16}{80}$	$\frac{1}{50}$
III.	7·5	$\frac{13}{80}$	$\frac{1}{47}$
IV.	11°	$\frac{22}{80}$	$\frac{1}{40}$
V,	6°	$\frac{13}{80}$	$\frac{1}{87}$
VI.	4·5	$\frac{10}{80}$	$\frac{1}{36}$
VII.	3°	$\frac{9}{80}$	$\frac{1}{26}$
VIII.	8°	$\frac{14}{80}$	$\frac{1}{45}$
IX.	7·5	$\frac{21}{80}$	$\frac{1}{28}$

The mean rise is $\frac{1}{40}$th of an inch for 1° Fahr.

Mr. Rennie then proceeds to calculate the theoretical rise from the expansion of iron, according to Lavoisier, in an arch of the dimensions of Southwark Bridge, for 50° increase of temperature.

The effects of changes of temperature were also observed in the stone bridge over the Thames at Staines. After the arches had attained their full settlement, openings were observed in the joints of the parapets immediately over the springing of the arches, and a distortion or sinking of the upper curve of the parapets. A wedge was inserted into some of these openings, and the lowest point of its descent in the month of January marked. The same wedges were carefully inserted every week until May, when they would no longer enter, and the joints became firmly closed. At this period, however, the joints immediately over the crowns of the arches, which had during the winter been quite close, were now open. From these facts it followed, as a necessary consequence, that in winter the arch contracting descended and the spandril joints opened, and in summer the arch expanding rose and [illegible] crowns. Thus the joints of the parapet, [illegible] made of single slabs of granite for the whole height, [illegible] of the changes of temperature. It had also been observed, [illegible] and other bridges, that joints made good in the winter with [illegible] cement were found crushed in summer.

With the view of obtaining some data for calculation, Mr. Rennie procured samples of granite, sandstone, and slate, and placing them in a properly constructed oven, ascertained the rates of their expansion, which are given in the paper.

A series of experiments was made at the request of the late Mr. Rennie by Mr. S. Walker, of Rotherham, on the variations in the length of 231 feet of the frieze, bolted together and laid on a firm platform. The temperature of the atmosphere and of the plates and the length were noted at five o'clock in the morning and at three o'clock in the afternoon, and in some of the experiments at seven o'clock in the evening. The details of these experiments are given in the paper.

The paper is accompanied by calculations for the rise of an arch and the opening of the spandrils for an increased temperature, and also by tables of the expansibility of different kinds of stones and irons given by Distigny.

"*Specification and Working Drawings of the Middlesborough-on-Tees Gas Works.*" By Peter Henderson, Assoc. Inst. C. E.

In this communication, the author details the several works, erections, and fittings of the Gas Works at Middlesborough-on-Tees, and the mode in which they are to be executed and completed.

"*On a mode of Dowelling Timber, to [illegible] and other materials for special purposes.*" By M. J. Brunel, [illegible] Inst. C. E.

The author proposes to unite timber by means of iron dowels and asphalte. Mastic had been used in the Tunnel works for the purpose of fitting small plates of cast iron to the poling boards. These, though constantly immersed in water and mud, and subject to severe hammering, had stood perfectly well. Asphalte is now used in preference to mastic, as it sets immediately. The author conceives that stone may be united by a similar kind of dowelling; and that wood may be interposed between stone and iron, so as to be used to advantage with the stone blocks, for the chairs of railways. Also, that this method may be used with great advantage in ship-building, in mast-making, and wherever any species of dowelling is required.

Feb. 21. — The President in the Chair.

"*On Steam Engines, principally with reference to their consumption of Steam and Fuel.*" By Josiah Parkes, M. Inst. C. E.

The above is the second and concluding communication on this subject; in the former, the generation of steam more particularly was considered; in the present, its application when generated. These are distinct questions, as it is the economy of steam which constitutes the dynamic perfection of a steam engine, whereas it is the economy of heat in supplying that steam which constitutes the perfection of the boiler as an evaporative vessel. These economic properties are totally independent of each other; they may co-exist in a maximum degree, or in very different degrees, and the degree of perfection which any particular class of engines, or which the particular engines of any class possess, is known from the weight of fuel burnt, of water evaporated, and the mechanical effect realized. As long as engines were constructed with but few varieties, or identical in their forms, the performance of one was a sufficient indication of the performance of all; but new forms of engines and new modes of practice being now introduced, a comparison of the performance on the several systems is a matter of deep practical and scientific interest. With the view of effecting this object, the author has collected all the authentic facts within his reach, and reduced them to common standards of comparison.

The effective power of steam engines may be ascertained either from the resistance overcome, or from the load upon the piston by means of the indicator; the former method being applicable to pumping, the latter to rotative engines. But the effective power of the steam in pumping engines, as thus ascertained, is far below the real effective power of the steam, and no exact comparison can be made by these means between the effective power of the steam in the two classes of engines. The useful effect is not synonymous with a true measure of effective power, since the duty is the true useful effect in a Cornish engine. The indicator when applied to the Cornish engines enables us to ascertain the absolute but not the effective power, so as to compare it with that of the rotative engine, since the friction of the engine and the load cannot be separately determined. The absolute power of the steam may also be ascertained from the relative knowledge of the elastic force of steam corresponding with the ratio which the volumes of water bear to each other. This theoretical estimate requires however several corrections; among which the steam condensed by contact with colder surfaces, the steam consumed in filling useless places, and that lost by priming, must be particularly noted.

The relative performance of pumping engines is well expressed by the term "duty," that is, the number of lbs. raised one foot by a given quantity of fuel; and of rotative engines by the term "horse power," that is, the number of lbs. raised one foot in a minute, divided by 33,000 lbs. the standard measure of a horse. The performance of the rotative engine may also be estimated by duty, and of pumping engines by horse power. The results of these computations for several engines are tabulated in this communication.

The sum of the latent and sensible heat being constant for steam of all elasticities, the expenditure of both power and heat is truly measured by the weight of water consumed as steam; this measure is free from all uncertainty, and independent of all theory: the weight of water as steam equivalent to the production of a horse power in each engine, and the duty effected by one pound of steam, will denote the positive and relative efficiency of the steam and the heat. These indices of efficiency being referred to some standard, we learn, from the preceding data, the precise value of each engine in its use of steam and fuel; of its boiling apparatus, as a generator of steam; of the comparative efficiency of the steam and coal, or economy of power and fuel. The results which may thus be obtained are also exhibited in tables, accompanying the communication.

The power resulting from the expenditure of equal weights of water, as steam, being known, the boiler may be connected with the engines, and the relative extent of heating surface employed to furnish their power shown. It will thus appear that equal measures of surface are quite inadequate to supply equal power, with equal economy, to different classes of engines. These results are tabulated in great detail, and it appears that the Cornish engineers now employ nearly eight times as much boiler surface for equal nominal power as that given by Watt's practice. But taking into account the fuel burnt per horse power per hour in the two cases - the Cornish engine consuming 2½ lbs. per horse power per hour, and Watt's engine 8½—the true relation of the boilers is as 19 to 1. Many other relations of a similar striking character may be deduced from these tables.

The detailed results of the experiments by Smeaton in 1772, on his improved Newcomen engine at Long Benton—by Watt, in 1786, on his rotative condensing engine, at the Albion Mills, are recorded in these tables; and it appears that the economy of the latter as regards steam and fuel was double that of the former, and approached very nearly to perfection in the use of power obtainable on that principle. The next great advance in the economy of fuel and power is that made by the Cornish engineers, whose performances, both with pumping and rotative expansive engines, far exceed any attained with the common inexpansive condensing engine. The superiority of two of these engines in 1835, doing a duty of 80 millions, exceeds the engines of Watt and Newcomen by 2½ and 5 times in economy of power, and by 3½ and 7 times in economy of fuel.

The obtaining a standard measure of duty is of great importance; a heaped measure, as a bushel of coals, is highly objectionable, as the weight of such measure will vary from 84 to 112 lbs. In the Cornish reports the bushel is fixed at 94 lbs. weight, as the standard of comparison, but some portion of a ton or one lb. would be a better standard. Other combustibles, however, as coke, peat, &c., may be used partially, or to the exclusion of coal, and under these circumstances some other standard of comparison is necessary, and with this view the author suggests a pound of water in the form of steam as the best standard of duty. The work done by a given quantity of water as steam is a sure index of the quality of the steam engine; it is a measure unaffected by variable calorific agents, and so long as engines continue to be worked by steam, so long will the performance of different engines be accurately gauged by their respective expenditure of water as steam. The accuracy of this measure depends on the physical fact of the constancy of the latent and sensible heat in steam of all temperatures. The author has recorded twenty-eight experiments made on twenty-eight different days, on vaporization from the boiling point to 60 lbs. pressure above the atmosphere, which present a remarkable confirmation of the above law, and show that the relative efficiency of steam in engines is due to the manner of using it, and not to any change in its chemical constitution at different pressures. The manner of conducting these experiments, and the precautions taken to ensure accurate results, are detailed with great minuteness.

The author next proceeds to treat of the Locomotive Engine, and to discuss, compare and tabulate the facts relating to this engine in the same manner as he has done those of the stationary class. The qualities of the boiler of the locomotive as an evaporative vessel had been discussed in the first communication. The locomotive differs from the fixed non-condensing engine only in the use of the blast, and the same method of measuring the effects of the steam are applicable to both. Experimenters on the locomotive have generally attempted to determine the amount of resistance opposed to its progress in preference to ascertaining the power expended in overcoming the resistance. The exact solution of either of these questions would furnish all that is wanted; but the ascertaining the total resistance by an analysis of its several constituents is attended with great difficulties, as the forces to which they are to be referred are so exceedingly numerous and variable, that the assigning the exact value to each at any one velocity has hitherto eluded the talents of those who have pursued this method. M. de Pambour was the first analyst whose labours will require attention. The results given by this author in his practical treatise on Locomotive Engines on Railways were compared by Mr. Parkes with the results which he had obtained when experimenting on an engine of precisely a similar character, and discrepancies presented themselves which appeared totally irreconcilable. These and other circumstances led the author to consider, whether the resistance to traction would properly be deduced from the laws of gravitation, or whether any certain results would be derived as to the amount of resistance on a level from observations on engines and trains moving down inclined planes. The great object seemed to be to discover some criterion of the mechanical effect produced by a locomotive at all velocities, which would apply as practically and as distinctly to a locomotive as duty to a pumping engine, or horse power to a rotatory engine. If this were possible, it seems of far less importance to distinguish the precise value of each particular unit of resistance, than to determine the relative sum of resistance and the relative expenditure of power at all velocities and under all circumstances. Now the term duty may be applied in the strictest sense of the term to the work done by a locomotive engine; for whether the engine drag a load whose resistance is 8 lbs. per ton, or whether a weight of 8 lbs. for each ton of matter moved descending over a pulley and attached to the load, be considered as the moving force, the result is the same. If, then, the tractive force, or resistance per ton of matter in motion, which is the real load on the engine, be ascertained, the whole effect is found by multiplying this sum by the space passed over in feet; and the consumption of water as steam and of coke being known, we have all the elements requisite for determining the duty performed by the steam or coke. The pressure against the pistons may be deduced from the sum of the resistances first calculated on the assumed resistance overcome at the velocity of the engine in each experiment; and the pressure on the pistons may also be deduced from the ratio of the volumes of the steam and water consumed. The results which may be obtained on these principles are tabulated, for the experiments of M. de Pambour, Robert Stephenson, and Dr. Lardner. In another table the author has recorded the reduction of each of these experiments to terms of horses' power, and has exhibited under that denomination the absolute power resulting from the steam used—that required to overcome the assigned resistance—their differences—and the power which balances the gross and useful duty. The construction of these most elaborate tables is described in great detail, and the consequences which follow from the tests thus obtained are fully stated, and the author comes to the conclusion, that results inconsistent with the capabilities of the locomotive are perceptible in almost every one of the experiments. A condensing engine placed on wheels, with water of condensation transported for its supply, and made to drag a train along a railway, would require the same expenditure of water as steam, to produce a given effect, as if fixed; a non-condensing engine also is one and the same machine, whether fixed or locomotive, excepting that the latter must consume more power than the former, to do equal work, at like pressures, by the amount of the additional resistance arising from the contraction of its eduction pipes, in order to produce a fierce blast of steam through the chimney. From these and other causes the fixed non-condensing engine must be the more economical of the two; but if the results derived from M. de Pambour's data be correct, we must acknowledge the fixed non-condensing engine, with its simple atmospheric resistance, to be far inferior in economy of steam to the locomotive, with its plus atmospheric resistance. The experiments by Dr. Lardner were made for the purpose of determining the resistance opposed to progressive motion on railways. They consisted in dismissing trains at various speeds from the summit of inclined planes, and in observing their velocity when it became uniform, the resistance at such velocity being equal to the accelerating force of gravity down the inclined plane. The results of these are tabulated in the same manner as the preceding, and the most singular discrepancies present themselves. For instance, it would appear that in one particular case a duty of double the amount of that effected by the condensing engine was performed by an equal expenditure of power; that compared with a fixed non-condensing engine at equal pressure, the locomotive, though labouring against the heavy counter-pressure of the blast from which the other is free, is assumed to have performed equal work with less than one-half the expenditure of power. That if the resistance assigned by Dr. Lardner as opposed to the progressive motion of the train be correct, the efficiency of the steam in the locomotive is more than double that obtained by the best condensing engines; more than treble that derived from stationary non-condensing engines, and equal to the performance of a Cornish expansive engine, doing a 50 million duty with a bushel of coals. With such results before us, the resistances assigned as opposed to and overcome by the locomotive at different velocities, must be regarded as utterly inconsistent with reality, and as resting on no solid foundation.

The preceding results show also that errors have crept in by the adoption of the theoretical method of reducing undulatory surfaces to a level. M. de Pambour extends the length of the road as a compensation for the acclivities or for the help afforded by the bank engines, and Dr. Lardner diminishes the time of the trip to that which he assumes would be occupied in performing it on a dead level. If the principles on which these corrections for the acclivities and declivities are made be correct, other facts than we are at present acquainted with must be taken into account before it can be demonstrated that a given power will convey a given load at some certain increased velocity along a level compared with the actual velocity along any given undulating line. The resistances which enter into the composition of the sum of the forces are ever varying to such an extent, that it may be doubted whether the theoretical level be not a pure fiction with reference to the practical results of the experiment.

The effective power of a locomotive engine, or the excess of power after overcoming its proper friction and the resistance from the blast, is solely expended in the generation of momentum. This which is the product of the mass and the velocity represents the useful mechanical effort exerted by the steam, and may always be ascertained under all the practical circumstances of railway traffic. The consumption of power as water, in the shape of steam, is a third quantity which may also be readily ascertained. The application which may be made of the above data is comprehended in the following propositions. First, that equal momenta would result at all velocities from an equal amount of power expended in equal times by the same engine, if the forces opposed to progressive motion and to the effective use of steam in the engines were uniform at all velocities. Secondly, the difference between the momenta generated by a unit of power in a given time at various velocities, measures the difference in the sum of the resistances opposed to the power at those velocities. Having ascertained the gross weight of an engine tender and train—their mean velocity—and the expenditure of water as steam during the trip, simple computations will inform us of

1. The mechanical effect realized by a given power at all velocities.
2. The total increase or decrease of resistance at all velocities.
3. The ratios which the increase or decrease of resistance at different velocities bear to the ratios of those velocities.

Two other results also follow from the above, and which may be termed the commercial results, viz. the amount of gross and useful tractive effect realized by an equal expenditure of power at all velocities. The difference between these is a useless quantity in a practical sense, being the costly waste of power incident to the locomotive functions of the engine and tender over and above the waste arising from the unascertained and ineffective portion of the whole power required for the blast. The reductions and computations necessary for the exhibition and development of these views are contained in two tables. They relate to forty-nine experiments, being those already referred to and those by Mr. N. Wood, on the Great Western, and London and Birmingham Railway, and some others. One of these tables contains the velocity of the engines, the consumption of water as steam, the loads, the absolute momenta per second; the momenta generated by equal power in equal times, viz. by 1 lb. of water as steam per second; the weights of the gross and useful loads moved by equal powers, viz. by one cubic foot of water as steam, at the velocity of each experiment, with various other elements. The other table contains a summary of the ratios of the velocities and of their squares, brought into juxta-position with the ratios of the power expended to produce equal momenta, equal gross and equal useful effects, by the comparison of pairs of experiments on the engines given in the preceding table. This table also shows the influence of velocity in the expenditure of power to produce equal mechanical and equal commercial effects; and the amount of loss attributable to the increase of resistance at the higher velocities. The author discusses in great detail the various circumstances of these experiments, and the inferences and practical conclusions which may be deduced therefrom; and comes to the conclusion, that the determination of the performance of locomotive engines by the methods here set forth is as practicable, exact, and demonstrative of their relative powers and dynamic excellence, as the determination of duty done by pumping engines.

The intensity of the pressure on the opposite side of the piston arising from the blast has been but imperfectly stated. By some the discharge of the steam has been likened to a jet, and considered continuous. But an attentive observer can appreciate by his ear that an interval exists between the alternate discharges of steam from the two cylinders. That these jets are periodic and not continuous, is also distinctly evidenced by the audible pulsations in the chimney, even at the very highest velocities of an engine, and their duration may be measured at lower speeds. Upon this intermittent action of the blast depend, in a great measure, the resultant pressure against the piston, and the production of a sufficient current of air through the fire, both which effects would be materially changed in intensity by the substitution of a continuous for a periodic current. The precise duration of the jet or of the time of the steam evacuating the cylinder, can only be determined by direct and careful experiments; but its period may be ascertained within definite limits; for since a single discharge is completed within the time occupied by the piston in accomplishing a half stroke, and the pauses between two successive discharges are distinctly perceptible, a single blast cannot occupy the fourth part of the time of the revolution of the crank shaft, and very probably does not exceed the eighth part, or the period of a quarter stroke of the piston. Under no circumstances, then, can the pressure from the blast oppose the piston much longer than during one fourth of the stroke. With an active pressure, then, of 30 lbs. per square inch, the mean resistance from the blast would not be greater than 7½ lbs., and with a pressure of 15 lbs. not greater than 3¾ lbs. per square inch, against the pistons. The author then proceeds to cite several observations and experiments made by himself, which are confirmatory of the preceding argument respecting the blast, and he was led conclusively to the fact, that one fifth of the power of the engine experimented upon, at working pressures of 20 lbs. and 15 lbs., was absorbed in blowing the fire; and that the escape of the steam from the cylinder was four times swifter than the motion of the piston.

The author lastly treats of the expenditure of power for a given effect by fixed and locomotive non-condensing engines. But few experiments on the expenditure of steam for a given effect by non-condensing stationary engines have been made. The relative consumption of fixed condensing and non-condensing engines has been treated of by the late Mr. Charles Sylvester, of Derby, whose knowledge and accurate theoretical analysis of the subject are shown by the close accordance of his conclusions with the facts established on two engines of these classes at certain working pressures. His conclusion that the relative economy of these engines will be as the quantities of steam consumed, or as 1 to 1·72, at those pressures, is accurately confirmed by the results here recorded. Mr. Sylvester also showed, that by increasing the pressure upon the same non-condensing, and by enlarging the area of the condensing engine's cylinder and air pump, so as to maintain the steam in it at a uniform pressure per square inch for all loads, the economy of the former would gradually approach and finally equal that of the latter. The results obtained in the preceding part of the paper, furnish numerous comparisons between the locomotive and fixed non-condensing engines, and the consumption of the latter has been used, together with the condensing engine, as the test of the accuracy of the data of resistance assigned to the former by the various analysis. The accurate determination of the expenditure of steam by the same locomotive engine, in which the values of the friction and of the blast pressure were ascertained, admits of the consumption of water as steam for given effects being determined, and thus narrows the grounds of doubt, and establishes more correct data for ascertaining the real resistance opposed to progressive motion on railways. The application of these principles, as borne out by the experiments of the author, and their particular bearing on the experiments which have been the subject of the previous ample and detailed discussion, form the conclusion of Mr. Parkes series of communications on steam boilers and steam engines.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

3rd Feb. 1840, W. R. Hamilton, Esq., Hon. Fellow in the Chair.

J. H. Good, jun., was elected an Associate.

A paper was read by Ambrose Poynter, Esq., Hon. Sec. entitled, "*some remarks on arabesque decorations, particularly those of the Vatican.*" An abstract of this paper appeared in the last months' Journal.

It is requisite that we should notice an error which occurred in the report of Mr. Poynter's paper on arabesque ornaments, in our last number. Some extracts had been selected from it, which owing to the unavoidable absence of the Editor, were inserted without the necessary connexion being supplied, and were, moreover, unfortunately misplaced in printing. We think this explanation due to Mr. Poynter—we hope that we shall be able, at some future opportunity, to print this very interesting paper in full, illustrated by engravings.

17th Feb., John Shaw, Esq., Fellow in the Chair.

Mr. C. H. Smith read a paper "*on the properties of various stones used for building.*"

At a Special General Meeting, 21st Feb., H. E. Kendall, Fellow in the Chair.

It was Resolved—That the President Earl De Grey be respectfully requested to present to her Majesty the following address on the part of the Institute.

ADDRESS.

The President, Vice Presidents and Members of the Institute of British Architects, deeply impressed with the honour conferred upon them by your Majesty's most gracious patronage, beg leave humbly to offer their sincere congratulations on the occasion of your Majesty's auspicious marriage.

That every blessing of this life may attend your Majesty and your illustrious Consort throughout a long and prosperous reign is the earnest prayer of your Majesty's most loyal and dutiful subjects.

2d March 1840, H. E. Kendall Fellow in the chair. The following gentlemen were elected Fellows:—Charles Parish, George Alexander, and David Brandon from the class of Associates;—Associate, Evan Christian.

T. L. Donaldson, Esq. Fellow, read a paper "*on the recent discoveries made at the Porta Maggiore, Rome,*" communicated by Signor Canina, Hon. and Cor. Member.

Mr. C. H. Smith read the conclusion of his paper "*on the properties of stone used for the purposes of building.*"

Monday, March 16, George Moore, Fellow, in the Chair.

The following gentlemen were elected: as Fellow, Edward I'Anson, jun.; as Associates, William Hinton Campbell, of Bath, and George Pownall.

Anthony Salvin, Fellow, presented ten guineas for the purchase of books.

T. L. Donaldson, Esq., read a paper on a system of framing for floors and roofs of large span, and applicable to bridges, whether of timber or iron, communicated by Herr Laves, architect of Hanover, Hon. and Cor. Member.

Question respecting the origin of the vertical line in architecture, and the return to the horizontal line in Italian buildings. By Sir Gardner Wilkinson, Hon. Fellow.

In offering the following observations to the consideration of the Institute, it is not my object to suggest, but to elicit an opinion upon the subject; feeling as I do that it would be presumption for me to do more than state the facts which have led to my remarks, when I had an opportunity of submitting it to those who are so capable of giving it a satisfactory explanation.

It is universally admitted that the principal features which distinguish Greek from what may be called Church Architecture, are the horizontal line in the former, and the vertical in the latter; and some have supposed that to church architecture is to be ascribed the origin of the vertical line. That it is common to buildings of the Saracens, the Lombards, the Saxons, and the Normans, as well as to those of the pointed style, is sufficiently obvious: thus far our experience tells us we have traced it, but beyond this, conjecture has not attributed to it an existence, nor has its origin been ascribed to any more remote source.

In the oldest Saracenic Mosques, erected about the middle of the 7th century, the style of architecture is evidently borrowed from Roman buildings. Their arches are simply imitative of the Roman style; the windows though small have a round arched head; the corridors are formed of avenues of single slender columns supporting round arches, and the type of the Roman original is readily traced; as in the earliest churches of Europe, which also present the round arch of the Roman style. But in both these we find the lines already vertical; and that this might be expected from what we see in the monuments of ancient Rome, is the point to which I wish particularly to advert.

Those buildings erected by the Romans in imitation of the Greek, as temples, and some other monuments of a borrowed style, present the horizontal line of that architecture to which they really belonged, and of which they were copies; and since we find this to be the case in all countries of modern Europe where Greek architecture is imitated (even though it is notorious that the vertical line is the prevailing feature of our taste) we cannot be surprised that the same should have been done by the architects of Rome. But whenever the Romans attempted any thing of their own, in which they thought a deviation from Greek models was allowable, we no longer perceive the horizontal, but the vertical line predominating; and to such an extent, that even a Greek entablature is sacrificed to this their favourite sentiment, being broken up into detached parts and compelled to project and recede, in order to allow the vertical line to pass continuously through it to the summit of the building.

In an arch of triumph, a Roman composition, though the mouldings and many other details are borrowed from the Greek, the vertical line commences with the pedestal of the columns appended to its side, and extending upwards with the column, breaks through the entablature, which it obliges to come forward to carry out and mark its direction, requires a projection of the attic to correspond with the capital above the cornice, and terminates in a statue; thus continuing it uninterruptedly from the base of the summit of the building. This is not confined to an arch of triumph; the same occurs in other monuments; a remarkable instance of which may be cited in the remains of the Forum Palladium, or Forum of Nero, (according to the Chevalier Bunsen), where the whole entablature is made to advance from the face of the wall to the distance of SEVERAL feet, and is crowned by a similar projection of the attic, in order to correspond with the vertical line of the column which supports it; and the same taste for breaking up the horizontal line of Greek entablatures may be seen in numerous Roman buildings, the neplus ultra of which occurs in the monstrosities of Petra.

Thus then we find the vertical line did not originate with the architecture of Christian Europe; it occurs in the monuments of ancient Rome; and this interesting question naturally suggests itself,—whence did it proceed, was it of Italian origin?—In the Rome of a Christian era the same occurs throughout its churches; which is the more remarkable, as those churches are not of what has been termed Gothic, but of Greco-Roman or of Cinque-cento style; and in these the vertical line extends from the lowest to the highest part. Even domes and cupolas are not exempt from its intrusion; it commences with the basement of the column, and extending upwards through the projecting entablature and the attic, it continues in bands over the whole convex surface of the dome, requires a corresponding pilaster or half column in the lantern, and exhausts itself only in the extremity of the cross, or whatever point terminates the building; a good example of which may be seen in the cupola of St. Peter's, whose façade, a memento of Bernini, not only unites the most glaring defects in taste, but affords an illustration of the worst application of the vertical line. After viewing these monuments, and observing the feeling which pervades them, every one must be surprised at the sight of the splendid palazzi of Rome, and other cities of Italy. In these we no longer perceive the vertical, but the horizontal line predominating, which is carried out with wonderful effect, both in the rich and splendid cornices that crown the building, and in the string courses beneath the windows. In these no broken entablature injures the harmony of the straight line, no sinecure columns are suspended at the side of the walls to do nothing but spoil the effect of the whole mass, and we perceive that their architects did not put together a number of details to form a whole, but conceived the whole, and made the details accessory to the general effect. So evident indeed is this, that the details are sometimes bad, and still the whole is excellent; as in many pictures of the great masters, where the composition and execution of the painting are of far greater importance, and far more striking to an artist than the imperfection of an accessory; like the sandal in the picture of Apelles.

Whence came it that Italy adopted this horizontal style, in which she has given such magnificent and graceful monuments? They are her own; and no Greek models were the origin of these noble conceptions. This is another interesting question; and it is with a view to obtain some explanation respecting *the origin of the vertical style in ancient Rome, and the return to the horizontal style in the palaces of modern Italy,* that I have offered the foregoing remarks to the Society; fully persuaded that many here present have been struck with the same curious facts, and are enabled to offer an explanation of them, which my inexperience on such a subject forbids me to suggest.

SELECT COMMITTEE ON RAILWAYS.

[SECOND REPORT TO THE HOUSE OF COMMONS.]

The select committee appointed to inquire into the state of communication by railways, and who were empowered to report their observations, together with the minutes of evidence taken before them from time to time, to the House; have further considered the matters to them referred, and have to report, that they have taken into their consideration the following clause which has been referred to them by the House:—

"And be it enacted, that no bridge or tunnel, or approaches to the same, for carrying a turnpike-road over or under any part of a railway or canal, shall be made or constructed of less width between the fences, walls, or parapets thereof than 21 feet; nor shall any bridge or tunnel, or approaches to the same, for carrying any other public carriage-road over or under any part of a railway or canal be made or constructed of less width between the fences, walls, or parapets thereof than 16 feet; nor in any case less than so much greater width, not exceeding 30 feet, as may be the average width of the turnpike or other public carriage-road for 100 yards on each side of that part of the railway or canal where any bridge or tunnel is intended to be made or constructed."

Your Committee have upon this subject examined Mr. Palk, the legal adviser of the Chairman of Committees in the House of Lords, and it appears from his evidence, that about the end of the year 1836, complaints were made to the Chairman of the Committees, and he introduced clauses into all subsequent railway bills, containing the provisions here annexed, and which your Committee will now proceed to compare with the clause referred for their consideration.

The rule which since that period has, with few exceptions, been adopted by the Chairman of Committees in the House of Lords, provides that the width of turnpike roads passing under bridges or tunnels should be 25 feet, and the width of highways passing under bridges or tunnels should be 15 feet.

The clause referred to your Committee for their consideration provides, that no bridge or tunnel for carrying a turnpike-road under any part of a railroad or canal shall be constructed of less width than 21 feet, and no bridge or tunnel for carrying any public carriage-road under any part of a railway or canal, shall be constructed of less width than 16 feet.

It will be perceived, therefore, that as regards a turnpike-road, the clause referred to your Committee requires a less width by four feet than has been required by the rule adopted in the House of Lords, while, as regards a highway or public carriage-road, an additional width of one foot is required more than has been deemed necessary by the regulations of the House of Lords. These regulations further provide, that the height of a bridge or tunnel passing under a railway should be 16 feet. This appears to your Committee to be also an important regulation. It will be found in the evidence annexed to the second report of the Committee on Railways in the last session, that it has been especially provided that the bridges or tunnels for carrying turnpike-roads under the Brighton Railway shall be 18 feet in height, and it is stated that this height was insisted upon for the convenience of the farmers and hop growers in that district. The rule of the House of Lords also requires that the width of a turnpike-road upon a bridge passing over a railway must be 25 feet, and the width of a public carriage-way 15 feet, with a parapet-wall in each case four feet high. A reference to the analytical table in the appendix to the second report of the Railway Committee of last session, will show that these regulations have been introduced into all the Railway Acts since the year 1836.

Your Committee would now recommend to the House that in all original Railway Acts, and in all Railway Acts authorizing new works in the present session of Parliament, the rule of the House of Lords should be adopted as to works to be carried into execution under the provisions of those Acts respectively, with this addition, that in every bridge or tunnel the arches should spring from abutments of not less height than 10 feet. Your Committee would also recommend that in all Railway Acts authorizing further works, passed in any future session of Parliament, the rule shall be as follows, with respect to works to be carried into execution under the provision of those Acts respectively:

Whenever a turnpike-road passes under a railway, the width of the bridge or tunnel shall in no case be less than 30 feet, and there shall be on each side footways of 2½ feet in width. Whenever a public carriage-road passes under a railway, the width of the bridge or tunnel shall be not less than 20 feet, and there shall be on each side footways of 18 inches wide; the height of the bridge or tunnel shall in no case be less than 16 feet, and the arches shall spring from abutments of not less than 10 feet in height.

Similar provisions might also, with advantage, be made applicable to all canal bills which shall in future be introduced into Parliament.

Statistics of Gas.—For lighting London and its suburbs with gas, there are 18 public gas works; 12 public gas work companies; 2,800,000*l.* capital employed in works, pipes, tanks, gas-holders, apparatus; 450,000*l.* yearly revenue derived; 180,000 tons of coal used in the year for making gas; 1,460,000,000 cubic feet of gas made in the year; 134,300 private burners supplied to about 400,000 consumers; 30,400 public or street consumers.—About 2650 of these are in the city of London.—380 lamplighters employed; 176 gas-holders, several of them double ones, capable of storing 5,500,000 cubic feet; 890 tons of coals used in the retorts on the shortest day, in 24 hours; 7,120,000 cubic feet of gas used in the longest night, say 24th December; about 2500 persons are employed in the metropolis alone in this branch of manufacture; between 1822 and 1827 the quantity nearly doubled itself, and that in five years; between 1827 and 1837 it doubled itself again.

Portsmouth Floating Bridge.—This bridge, which will shortly be opened, is seventy feet in length, and sixty in breadth, and is capable of holding on each side, besides passengers, two rows of carriages seventy feet long; she is impelled by two engines of twenty-horse power each, the cylinders being eighteen inches in diameter, and the length of the stroke three feet. The average rate of the engines will be about thirty strokes per minute, and the average speed about 350 feet per minute; so that she will perform the passage (2200 feet) in about seven minutes. She only draws, with all her machinery on board, two feet and nine inches, and fifty tons additional weight will only sink her four inches.

STEAM NAVIGATION.

The *Nemesis* iron steam ship, 165 feet long, 29 feet beam, 660 tons, built by John Laird, of the Birkenhead Iron Works, Liverpool, with engines of 120 horse power, made by George Forrester and Co. Liverpool. On her passage from Liverpool for Odessa, she struck on a sunken rock when going 9 knots per hour the damage she sustained was trifling, requiring only about 2½ cwt. of new iron, and 12 men about 6 days to repair it; not a rivet was started—the injury was confined to the part actually *dinged or cut*; the repairs might have been completed in three days at Liverpool, where every convenience could have been had. It is stated by some parties, well acquainted with the circumstances, that had the vessel been timber built, she would not have been got off at all; but all agree that had she got off the repairs would have been both tedious and very expensive. The leak caused by the blow was so trifling that the *Nemesis* might have steamed for months without being obliged to dock. The accident occurred about the 10th ult., she steamed 300 miles afterwards, was discharged, docked, repaired, reloaded and ready for sea again by the 26th ult., with all her stores and coals on board.

PROGRESS OF RAILWAYS.

CROYDON RAILWAY.

Mr. Cubitt's Report to the Directors on the Cost of constructing the Railway.

[We have given this report in full, as it contains a great deal of valuable information to the profession.]

Gentlemen, *London, March 9, 1840.*

"The object of this report is to set forth the cost of constructing the Croydon Railway.

"In performing this duty it will be necessary to refer back to a period previous to the general meeting in August last, at which time the affairs of the Company were undergoing an examination by a committee of proprietors, by whom I was called upon, to aid and assist them in their labours.

"As much dissatisfaction at that time existed with regard to the great cost of the works and the little information which existed on the subject, it occurred to me that nothing could tend to satisfy the minds of the proprietary so much as a clear statement of the cost of all the various parts of the work, and in a short report of the Committee of the 7th of August, I stated the way and manner, and the number of heads in which I recommended the accounts to be called for, and which were as follow:—

I. Acts of Parliament, including all legal and professional charges of all kinds incurred in soliciting and passing the various bills; the whole drawn out in a detailed form.

II. Land, buildings, and compensations of all kinds for the line of railway, and stations, together with all legal charges attending the same, and the expenses of all kinds attendant on obtaining possession of the land, &c., in detail.

III. Earthwork, bridges, fencing, draining, and forming the line of railway, as per contracts and otherwise, and also all extras upon contracts, setting forth in a clear and detailed form the whole cost of formation, bridging, fencing, draining, &c., up to the line of ballasting.

IV. Ballasting, sleepering, and laying the permanent way complete, including all turn-plates, sidings, and expenses of all kinds attending the trackways of the line.

V. Water apparatus, including engines, pumps, standards, pipes, and erections of all kinds relative to supplying the locomotive engines with water.

VI. Stations, showing the amount of contracts, and an account in detail of all extras thereon.

VII. Engine and carriage houses, workshops, implements, machinery and apparatus of every kind, for repairing and maintaining the locomotive engines, &c.

VIII. Wharfs, railway cranes, and works connected with the Grand Surrey Canal Junction.

IX. Sundries of various kinds not reducible to the above heads.

X. Engineering and supervisal of all kinds.

"Such were the accounts which I recommended the Committee to obtain, and which statement was remitted to the engineer as instructions to furnish to me, in detail, the accounts as therein specified.

"This requisition, which involved much labour and of necessity would occupy a great length of time, was most readily and cheerfully responded to by Mr. Gibbs, who not only caused the whole of the engineering accounts and expenditure to be arranged in detail under their respective heads, from III to IX. inclusive, but induced Messrs. Grissel and Peto, the contractors for the stations and buildings, to do the same with all their work, and who, much to their credit and at a very heavy expense, furnished in detail a minute account of all the work executed by them for the Company.

"To the heads, Nos. I, II, and X, I have not received any returns, but as they form no portion of the construction of the railway, and the first two not being in the engineer's department, and the last relating to private and personal accounts of the Company, may be considered as sufficient reasons for not being included in this inquiry.

"As it will be difficult, if not impossible, in a report of this kind, (which is intended to afford as much general information as possible in the shortest compass, and in a way to be understood by the general body of the proprietors) to enter very minutely into the accounts, I shall therefore submit to the board a general abstract or statement of the whole work, under the separate heads contained in my instructions, dividing each head into the principal items or costs of which it is composed, and refer for further particulars to the books themselves, premising that every entry in the book, or statement furnished to me, is referred to original day-book, journal, or ledger, in which the accounts have been entered and kept; and I have the assurance of the parties by whom the accounts have been analyzed, that out of the whole amount there are not 500*l* for which vouchers are not producible, and which, in so large an amount, of which I had heard it surmised that no regular accounts had been kept, I think it very unsatisfactory.

"Of course, it is not in my province to go through and compare every entry in a voluminous and mixed set of accounts; a return has been made to me, as nearly as possible in the spirit and letter of my instructions, and that not in the form of a mere abstract but in great detail, and with every entry referred to the book from which it was extracted; which books, also, as before observed, were sent to me for inspection, and are now in my possession; and if it would be any satisfaction to the board or the proprietary, I shall have no objection to attend the general meeting therewith, and to afford any information and explanation in my power on the subject; but the following abstract of the accounts will show in what way the capital of the Company has been disposed of, as far as works, buildings, and machinery, are concerned.

"Such is the statement of cost which I have been enabled to make out and submit to the meeting, and which I have no reason to think is otherwise than correct, depending of course on the correctness of the data from which it was formed, but which I have no cause to doubt; the books, however, are before the meeting, and will be found I think, to bear both external and internal evidence of being original documents, with entries made at the time; and in my judgment not the less valuable in this case for not being the most perfect system of bookkeeping that could be devised.

"As regards the correctness of the charges and the amount of works done over and above the contracts, there is no means of proving it in every instance, especially in day-work and sundries, which form a large amount. An approximate check might certainly be obtained as to the success of cuttings in flattening slopes, and getting out slips in the large contracts, by going into a remeasurement of those portions of the work, but this would involve a considerable expense, and it is doubtful whether the result would justify the expense to be incurred; still I am ready to go into it if the Board think it proper to do so. In connection with this part of the subject, it is due to the engineer to state, that I have been furnished with the cross sections and dimensions of all the extra cuttings from which the accounts were deduced; and in conclusion, I may be again allowed to observe, that on the part of Mr Gibbs, your principal engineer, and Mr. Dean, the assistant engineer, there has been no lack of information, and that my acknowledgments are due to those gentlemen for the promptitude and readiness with which my inquiries have at all times been met.

"On the whole, then, after a careful and laborious investigation of the subject, I have no hesitation now in recording as my deliberate opinion, that which I had the honour to express verbally to a meeting of this Company some time before the railway was open to the public and whilst the conduct of the Board at that time and the state of the expenditure were under the investigation of a Committee, viz.—that as far as the works are concerned (excepting any errors of admeasurement), there is value received, although probably at a high price, on account of circumstances in materials and labour for the money; and that the railway is well and durably laid; and that whatever want of judgment there may have existed in making out the original estimates, and lack of knowledge as to the extent to which the works would ultimately be carried, there has, in my opinion, been no want of honesty either in the management or the executive, as regards the execution of the works.

I have the honour to be, &c.,

"W. Cubitt."

TABLE OF COSTS.

Head No. III. of Instructions—Formation of Line.

	£	s.	d.
1st—Earthwork.			
Forest Hill	26,703	13	9
New Cross Hill	30,131	2	4
Sydenham	11,718	2	3
Croydon	4,527	5	9
Total of Earthwork	73,080	4	1
2nd—Fencing, Draining, and preparing for Ballast, &c.			
Forming the way	426	0	4
Fencing, soiling slopes, &c.	4,649	11	6
Fencing and planting	6,763	3	7
Surface draining	2,817	19	6
Gates	486	0	2
Slips and extra slopes	11,138	11	11
Total forming Slips, &c.	26,281	15	0
3rd—Bridges and Culverts.			
Viaduct at Corbet's Lane	9,374	13	8
Boundary Walls at ditto	559	6	3
Timber Viaduct	2,505	15	0
Black Ditch Bridge	5,062	6	10
Surrey Canal Bridge	7,361	11	1
Cold Blow Farm ditto	618	12	2
Footbridge, Five Bell Lane	456	14	6
New Cross Bridge	3,161	7	0
Finches' Bridge	2,603	9	5
Deptford Common Bridge, No. 1	628	8	6
Ditto ditto No. 2	1,102	3	0
Calgate's Bridge	1,353	12	10
Owen's Bridge	1,032	12	11
Colson's Bridge	873	18	8
Sydenham Bridge	2,981	7	6
Anerley Bridge	1,761	13	6
Jolly Sailor Bridge	2,612	5	1
Croydon Common Bridge, No. 1	1,069	3	10
Ditto ditto No. 2	1,136	0	11
Cross Road Bridge	1,394	2	0
Total of Bridges	47,649	4	8
4th—Culverts.			
Deptford Common Culvert	451	5	4
Ditto ditto	412	9	3
Forest Wood ditto	129	0	9
At New Cross	1,418	18	11
" Sydenham	1,786	19	1
" Selhurst	115	17	9
Total of Culverts	4,315	1	1
5th—Retaining and Boundary Walls.			
Turner's and Sterry's	666	1	8
At Sydenham Bridge	3,451	7	3
Sydenham Station Walls	374	0	7
Jolly Sailor ditto	611	12	3
Dartmouth Arms ditto	1,513	14	8
Sundry Walls	141	0	2
Total of Retaining and Boundary Walls	6,757	16	7
6th—Diversion of Roads, &c. &c.			
At Cross Roads Bridge	418	11	7
Brockley Road	15	15	6
Dartmouth Arms ditto	543	1	0
New Cross	533	3	11
Viaduct Road	73	4	9
Sydenham Bridge	33	19	0
Jolly Sailor	101	3	0
Penge and Anerley Roads	350	0	0
Approaches to Nos. 1 & 2 Bridges	770	13	4
Surrey Canal Bridge Road	13	16	9
Sundry other Roads	1,936	15	0
Total making and altering Roads, &c. &c.	4820	3	10
Total of construction to Formation level	162,904	6	3

Head No. IV. of Instructions, viz.—Ballasting, Draining, Timbering, and laying Permanent Way.

	£	s.	d.
1st—Ballasting the Line, exclusive of London Bridge Station	17,373	15	0
2nd—Drainage of Permanent Way	2,788	1	10
	20,161	16	10
3rd—Timbering the Line.			
Sleepers, timber, and preparing do.	24,890	8	10
Carriage of timber	1,943	9	2
Kyanizing ditto	4,793	3	8
Laying sleepers	5,113	8	2
Tarring ditto	223	17	11
Felt for rails	663	5	10
Total of timbering the line	37,627	13	7
4th—Rails and Laying.			
Rails, screws, and bolts	24,785	10	8
Labour and laying rails	968	17	0
Carriage, and removal by hand of ditto	1,847	19	5
Turnplates	2,151	1	10
Total of laying rails	29,753	8	11
	87,542	19	4

Head No. V. of Instructions.—Water Supplying Apparatus.

	£	s.	d.
At London Bridge Station	923	10	1
New Cross ditto	3,190	2	11
Croydon ditto	1,555	2	2
Total of water apparatus	5,668	15	2

Head No. VI. of Instructions—Cost of Stations.

	£	s.	d.
At London Bridge	40,301	5	8
New Cross	21,919	18	5
Dartmouth Arms	1,344	10	8
Sydenham	134	3	4
Penge and Anerley	454	2	4
The Jolly Sailor	2,366	0	4
Croydon	12,215	19	9
Total of Stations	78,736	0	6

Head No. VII. of Instructions, included in No. VI.

Head No. VIII. of Instructions—Wharfs at Surrey Canal Junction and Croydon.

	£	s.	d.
1st—Surrey Canal Wharf and Incline	5,022	5	10
2nd—Croydon Wharfs.			
Wharf walls	2,750	17	5
Crane	37	0	10
Warehouses	968	4	0
Stables	86	3	0
Total of Wharfs	3,842	5	3
	8,864	11	1

Head No. IX. of Instructions—Sundries of various kinds, including Locomotive Engines, Carriages, Waggons, Consolidation of Way, &c. &c.

	£	s.	d.
1st—Houses and Cottages.			
Police Cottages	691	19	10
Switch Box at Junction	38	7	7
Ditto ditto at New Cross	33	8	0
Cottage at Brockley	199	12	3
Ditto ditto Sellhurst	12	0	6
Storehouse, Coldblow	64	16	0
	1,040	4	2
2nd—Lighting.			
Light House at Junction	369	10	5
Expenses for Lighting Road.			
New Cross Station	374	10	0
Croydon Station	232	6	0
London ditto	302	1	1
Engine lamps, &c.	223	8	4
Light House at Junction	89	4	7
Ditto	349	18	7
	1,940	19	0
3rd—Consolidation of Way	11,146	18	10
4th—Locomotive Engines, Carriages, and Waggons	28,086	3	6
5th—Miscellanea and Sundries of all and various kinds	18,054	17	5
	60,269	2	11
Total	£403,985	15	3

"From the annexed statement arises the following general abstract, under the different heads of my instructions, viz.—

	£	s.	d.
Construction and formation of the line of railway to the line of ballasting	162,904	6	3
Ballasting and laying the permanent way	87,542	19	4
Buildings and machinery for supplying water to engines	5,668	15	2
Stations, workshops, &c.	78,736	0	6
Wharfs at Surrey Canal and Croydon	8,864	11	1
Sundries of various kinds, including locomotive engines, coaches and waggons, consolidation of way, &c.	60,269	2	11
Total cost of construction and setting to work	£403,985	15	3

Exclusive of land, parliamentary and law expenses, and engineering.

MANCHESTER AND BIRMINGHAM RAILWAY REPORT.

Mr. Buck's Report to the Board of Directors, (March 3, 1840.)

Fairfield Street Contract.—This contract is finished, with the exception of the bridge over Fairfield-street. The ironwork of this bridge is now in course of erection. Half of the main ribs are fixed, and I expect that in seven weeks from this date, all the roadway plates will be fixed, and the bridge ready to receive the ballasting. In my report of last September, I stated that the founder had undertaken to have the ironwork erected by the end of December last; however, he has been unable to work up to his calculations in this respect, by reason of the extraordinary wetness of the weather, which prevented the workmen from continuously proceeding with the fitting of the castings; an operation which, (from the nature of the work,) was necessarily performed in the open air. But it is satisfactory to state, that although some additional time has consequently been requisite for this portion of the work, the opening of the line to Stockport will not be retarded thereby.

Chancery Lane contract is finished, and the contractor for laying the permanent way is now ballasting the arches.

Hyde Road Contract.—The brick arches are all turned and ballasted, in readiness for the permanent way. About one-third of the parapet remains to be built. The ironwork for the cast iron arch over the Hyde Road, is now in progress of erection; all the main ribs, and a portion of the spandrills are fixed. I expect that the roadway plates will be ready for the ballasting in four weeks from this time.

Heaton Norris Contract.—The excavation is very nearly finished: about 8,000 yards only remain to be moved, in addition to that which has been reserved for ballasting the permanent way; and this will go out as wanted for the purpose. An opening remains in the embankment at the crossing of the Stockport Road and its diversion, where two temporary bridges have been erected during the construction of the permanent one. The masonry for the latter is at the height for the reception of the iron arch, which is ready, and will require about eight weeks for fixing. This is the only bridge *under* the line which is not built. Of the bridges *over* the excavation, there are five of various sizes in different states of forwardness, three being nearly finished. These will all be easily completed during the time of fixing the ironwork of the Stockport Road bridge. Of the permanent way, 5,100 yards of single road have been, and 13,400 yards remain to be laid. Here more was calculated upon, but the contractor has been unable to procure sleepers so rapidly as he expected; however, in consequence of recent arrangements which he has made in reference to a more expeditious delivery, I have every confidence in his completing the whole within the period of his contract.

Stockport Viaduct Contract.—The north abutment and seven arches are finished; three other arches are in different states of forwardness, and the centre is fixing for the eleventh. The pier on the right margin of the river Mersey is erected to the height of the impost, which is partly set; the preceding ten arches comprehend all that portion of the work on the north or Lancashire side of the river. The foundation of the river pier on the left margin is just commenced. Five other piers on the south or Cheshire side are in progress, one being nearly finished, and the others in proportionate states of advance. The foundations of the three next in succession are excavated, and the south abutment is partially erected. I have great satisfaction in stating that all the foundations are upon rock.

Castle Street Contract extends from the south abutment of the Stockport Viaduct to the Mecca Brook, a distance of two miles six chains. The contractor has just commenced operations.

The designs are prepared for that portion of the line extending from the end of the last mentioned contract to Alderley, a distance of seven miles seven chains.

I have every confidence that my former statement will be realised, and that the line from Fairfield-street to Stockport may be opened in the month of May next.

Midland Counties Railway.—This line of railway will be opened from Nottingham and Derby to Leicester, in May next, and throughout to Rugby in June, in time to receive the traffic when the whole line of the North Midland is opened. This important railway is one of the few in England that will be made with the original subscribed capital. It will be in full operation without the creation of either half or quarter shares; and notwithstanding the pressure in the money-market, so great has been the confidence in this undertaking, that the directors have already been enabled to borrow nearly the whole sum authorised to be taken on loan by their Act. The cost of the line, including every thing, will only be about 22,500*l.* per mile.—*Railway Times.*—This railway will untimately become one of the most important lines in the kingdom, particularly if an act should be obtained for the Nottingham, Lincoln and Hull railway, which is sure to be carried into execution sooner or later.

Gloucester and Birmingham Railway.—This company appear to be using their utmost exertions to hasten operations along that portion of the line promised, in their late report, to be opened in the spring. On Monday last the directors and engineers inspected the works at the Cheltenham station, with the state and condition of which they expressed themselves much pleased; and, proceeding on the railroad to Tewkesbury, examined in like manner the different works in that neighbourhood. The return from Tewkesbury was accomplished in sixteen minutes; we believe the distance has been gone over before in thirteen. The engines to be employed on this line, if that now at work is to be taken as "a sample for all the rest," promise to equal, if not excel, those of any of the other railroads in the kingdom.—*Cheltenham Looker-on.*

MISCELLANEA.

A buried Village.—We find, in the *Progres du Pas de Calais*, the following account of the accidental discovery of a subterraneous village in the commune of Hermies, near Bapaume, which we are inclined to receive with some hesitation, till we meet with a confirmation of the statement. It is therein said, that during the late heavy rains a great land-slip took place close to Hermies, into which some of the young men of the place had the hardihood to descend, by means of ladders tied together. What was their surprise, to find themselves, at a depth of thirty metres, in the midst of handsome streets, bordered on both sides by cells and chambers, which had evidently been once inhabited! The streets are of width sufficient to admit of a carriage passing; and the chambers, of various sizes, are also of various degrees of comfort and elegance. Some are flagged, and their number is said to amount to between twelve and fifteen hundred. Among the objects by which the explorers were more particularly struck, was an old stone tower, with a winding staircase. This they ascended, and, having beaten through the vaulted roof, discovered that it opened into the belfry of the church of Hermies.

Architecture.—The Rev. John Parker, M.A. lately delivered a course of Lectures on Gothic Architecture before the members of the Shropshire and North Wales Natural History and Antiquarian Society. The lectures were principally directed to an explanation of the scientific construction of gothic vaulting, with a dissertation on the superiority of the upright or pointed gothic arch over the circular arch of the Anglo-Norman and other schools of architecture. The pre-eminence of the gothic vault in the conveyance of sound, and of the upright or pointed arch in the great particulars of lightness and strength, were clearly shown and most happily described.—Sections of ribbed work from gothic vaulting in Valle Crucis Abbey, the Castle of Beaumaris, Tintern Abbey, the Old Chapel of St. Stephen (the late House of Commons), Shiffnal Church, the Priory of Kenilworth, the White Abbey (in this county), St. David's Cathedral, Lichfield Cathedral, and Stoneleigh Abbey, were produced, with a model in wirework that pourtrayed the several forms in which the ribbed work of gothic vaulting could be made available by the artist; while the superiority and beauty of the pointed arch were illustrated by drawings made by Mr. Parker on visits to Kilpec Church, near Hereford, and to the ruins of Valle Crucis Abbey, aided by the more simple but effective application of scientific acquirement to that practical illustration which the course of lectures required to be made during the progress of its delivery.—*Salopian Journal, Feb. 5, 1840.*

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 29TH FEBRUARY, TO 28TH, MARCH 1840.

JAMES BEAUMONT NEILSON, of Glasgow, Gentleman, for "*certain improved methods of coating iron under various circumstances, to prevent oxidation or corrosion, and for other purposes.*"—Sealed February 29; six months for enrolment.

ROWLAND MACDONALD STEPHENSON, of Upper Thames Street, Civil Engineer, for "*an improved method or methods of adjusting, shifting, and working theatrical scenery and apparatus.*"—February 29; six months.

RICHARD EDWARDS, of Fairfield Place, Bow, Dealer in Emery Cloth, for "*improvements in preparing and combining of materials used in lighting or kindling fires.*"—February 29; six months.

JOHN SYLVESTER, of Great Russell Street, Engineer, for "*improvements in the construction of doors and frames for closing the openings of fire places, ash pits, flues, chimneys, and certain retorts.*"—March 3; six months.

JOSEPH SHORE, of Birmingham, Merchant, for "*improvements in preserving and covering certain metals and alloys of metals.*"—March 3; six months.

JAMES HORNE, of Clapham Common, Esquire, for "*improvements in the stuffing-boxes of lift pumps.*"—March 3; six months.

JOSEPH CLISILD DANIELL, of Limpley Stoke, Bradford, in the county of Wilts, for "*an improved method of preparing shoot or weft to be used in weaving woollen cloth and cloths made of wool and other materials.*"—March 3; six months.

JOHN RANGELEY, of Camberwell, Gentleman, for "*improvements in the construction of railways, and in the means of applying power to propelling carriages and machinery.*"—March 3; six months.

WILLIAM CRAIG, of Glasgow, Engineer, and WILLIAM DOUGLAS SHARP, of Stanley, Perthshire, Engineer, for "*certain improvements in machinery for preparing, spinning, and doubling cotton, flax, wool, and other fibrous substances.*"—March 3; six months.

JOSEPH NEWTON, of High Bridge Mill, York, Manufacturer of Fancy Cloths, and GEORGE COLLIER, of the same place, Mechanic, for "*an improvement in looms, for the weaving of figured or twilled fabrics.*"—March 4; six months.

JOSEPH BOWER, of Hunslet, York, Soda Ash Manufacturer, for "*certain improvement in the manufacture of carbonate of soda.*"—March 4; six months.

CHARLES ALEXANDER PELLERIN, of Leicester Square, Gentleman, for "*improvements in wind and stringed musical instruments.*" Communicated by a foreigner residing abroad.—March 4; six months.

CHARLES KOBER, of Leadenhall Street, Cloth Manufacturer, for "*improvements in fixing colour in cloth.*"—March 7; six months.

CAROLINE JULIA SOPHIA COX, of Addison Road, Kensington, Spinster, for "*an improved mode of fastening and uniting the edges of the divided parts of shoes, boots, bandages, packages, and other articles of dress or utility.*"—March 7; two months.

JOSEPH ATKINSON, of Roundhill, York, Farmer, for "*improvements in thrashing and winnowing-machine.*"—March 7; six months.

ROBERT MOLYNEUX, of Southampton Row, Chronometer Maker, for "*an improvement or improvements in chronometers.*"—March 7; six months.

William Maltby, Junior, of Mile End, Chemist, and Richard Culerton, Junior, of Percy Street, Brass Founder, for "*improvements in extracting and concentrating the colour, tanning, and other matter contained in vegetable and animal substances.*"—March 7; six months.

Luke Hebert, of Birmingham, Civil Engineer, for "*improvements in the manufacture of cofered spades and shovels, soughing and grafting tools, and other implements of a like nature.*"—March 7; six months.

Hayward Tyler, of Milton Street, Cripplegate, Engineer, for "*certain improvements in machinery or apparatus for impregnating liquids with gas, including bottles for retaining, keeping, and preserving liquids so impregnated, also in the manner of filling and closing such bottles.*"—March 7; six months.

James Knowles, of Little Bolton, Lancashire, Coal Merchant, for "*an improved arrangement of apparatus for regulating the supply of water to steam boilers.*"—March 10; four months.

George Gwynne, of Portland Terrace, Regent's Park, Gentleman, for "*improvements in the manufacture of candles, and in operating upon oils and fats.*"—March 10; six months.

William Forrester, of Barrhead, Renfrew, Manager, for "*certain improvements in sizing, starching, dressing, and otherwise preparing warps for weaving fabrics, and on the machinery and apparatus therewith connected.*"—March 11; six months.

Thomas Peel, of Bread Street, Cheapside, Gentleman, for "*certain improvements in steam engines.*" Communicated by a foreigner residing abroad.—March 11; six months.

Richard Smith and Richard Hacking, of Bury, Lancaster, Machine Makers, for "*certain improvements in machinery and apparatus for drawing, slubbing, roving, and spinning cotton, wool, flax, silk, and other fibrous substances.*"—March 13; six months.

Etienne Robert Gaubert, of Paris, Professor of Mathematics, for "*certain improvements in machinery or apparatus for distributing types or other typographical characters into proper receptacles, and placing the same in order for setting up after being used in printing.*"—March 13; six months.

James Hadden Young, of Lille, in the kingdom of France, and Adrian Delcombe, of Lille aforesaid, for "*an improved mode of setting up types.*"—March 13; six months.

Robert Varicas, of Burton Crescent, Surgeon, for "*improvements in rendering fabrics and leather waterproof.*"—March 16; six months.

William Crofts, of Radford, Nottingham, Machine Maker, for "*improvements in machinery for the purpose of making figured or ornamented bobbin net or twist lace, and other ornamental fabrics, looped or woven.*"—March 16; six months.

Jean Francois Victor Fabien, of King William Street, London, for "*improvements in rotary engines to be worked by steam or other fluids.*"—March 16; six months.

Thomas Craddock, of Broadheath, Radnor, Farmer, for "*a certain improvement or improvements in steam engines and steam boilers.*"—March 16; six months.

Richard Smith and Richard Hacking, of Bury, Lancaster, Machine Makers, for "*certain improvements in machinery for spinning cotton and other fibrous substances.*"—March 16; six months.

Isham Baggs, of Cheltenham, Gentleman for "*improvements in engraving, which improvements are applicable to lithography.*"—March 17; six months.

Moses Poole, of Lincoln's Inn, Gentleman, for "*improvements in producing and preparing leys for soap making, and in the manufacture of soap.*" Communicated by a foreigner residing abroad.—March 17; six months.

Samuel Seaward, of the Canal Iron works, Poplar, Engineer, for "*certain improvements in the construction of steam engines and in the application of steam engines to propelling ships and other vessels.*"—March 17; six months.

Sir William Burnett, Knight, of Somerset House, for "*improvements in preserving animal, woollen, and other fibrous substances from decay.*"—March 19; six months.

John Jackson, of Manchester, Nail and Bolt Manufacturer for "*certain improvements in the manufacture of nails, nuts, bolts, and rivets.*"—March 19; six months.

Thomas Sterling, of Limehouse, Patentee of the "rapid filterer" for "*improvements in the manufacture of fuel.*"—March 20; six months.

Francis William Gerish, of East Road, City Road, Patent Hinge Maker, for "*improvements in locks and keys and other fastenings for doors, drawings, and other such purposes.*"—March 20; six months.

Charles Keene, of Sussex Place, Regent's Park, Gentleman, for "*improvements in producing surfaces on leather and fabrics.* Communicated by a foreigner residing abroad.—March 23; six months.

William Newton, of Chancery Lane, Civil Engineer, for "*certain improvements in the strengthening and preserving of ligneous and textile substances.* Communicated by a foreigner residing abroad.—March 23; six months.

Samuel Hill, of Sloane Street, Chelsea, Gentleman, for "*improvements in the making of bread and biscuits.*"—March 25; six months.

Elhanan Bicknell, of Newington Butts, Surrey, Merchant, for "*improvements in separating the solid from the liquid parts of tallow, and other fatty matters.*" Communicated by a foreigner residing abroad.—March 25; six months.

William Palmer, of Sutton Street, Clerkenwell, for "*improvements in the manufacture of candles, and in apparatus for applying light.*"—March 25; six months.

Henry Smith, of Birmingham, Lamp Manufacturer, for "*improvements in gas burners, and in lamps.*"—March 25; six months.

George Richards Elkington and Henry Elkington, of Birmingham, for "*improvements in coating, covering, or plating certain metals.*"—March 25; six months.

Joseph Crosfield, of Warrington, Soap Maker, for "*certain improvements in the manufacture of plate glass.*"—March 25; six months.

Samuel Knight, of Woodhouse Mills, Lancaster, Bleacher, for "*certain improvements in machinery or apparatus for boiling, bleeching, or scouring, for the purpose of preparing and assisting the process of bleeching and dyeing cotton and linen, and other fabrics and fibrous substances.*"—March 25; six months.

James Hay, of Belton, Haddington, Scotland, Captain in the Royal Navy, for "*an improved plough, which he entitles the Belton plough.*"—March 25; six months.

Henry Philip Rouquette, of Norfolk Street, Strand, Merchant, for "*a new pigment.*" Communicated by a foreigner residing abroad.—March 25; four months.

James Sabberton, of Great Pultney Street, Golden Square, Tailor, for "*a fastening to attach straps to the bottoms of trousers.*"—March 26; two months.

Alexander Southwood Stocker, of Birmingham, Manufacturer, for "*certain improvements in manufacturing tubing or tubes, which are applicable to gas and other purposes.*"—March 27; six months.

Richard Prosser, of Cherry Street, Birmingham, Civil Engineer, for "*certain improvements in machinery or apparatus for manufacturing pipes.*"—March 27; six months.

Henry Kirk, of Upper Norton Street, Portland Place, Merchant, for "*improvements in the application of a substance or composition as a substitute for ice for skating and sliding purposes, part of which improvements may also be employed in the manufacture of ornamental slabs and mouldings.*"—March 28; six months.

John Bethell, of St. John's Hill, Wandsworth, Gentleman, for "*improvements in treating and preparing certain oils and fatty matters.*"—March 28; six months.

ERRATUM.

In Mr. Leeds Chronological Table of Architects, page 113 of the present number, the works of the second architect are omitted, it should stand thus. 1708, Mansard, Jules Hardouin, 1647,—*works*, Palace of Versailles; Dome of the Invalides, Paris; &c.

TO CORRESPONDENTS.

Mr. Spencer's *communication is unavoidably postponed until next month.*

P. P. E.'s *scheme for propelling canal boats we are fearful is impracticable, however, we will reconsider it before the next number appears.*

X. Y. Z. Glasgow. *We shall feel much pleasure to record in the Journal, the many improvements that are going on in Glasgow, if our correspondent will take the trouble to see some of the architects of the North and collect information for us, we shall be obliged.*

Mr. Thorold's *design for a frame of a steam engine possesses considerable merit for its compactness, as there is no novelty in the construction of the machinery, we cannot afford space for the design at this busy season of the year.*

R. W. T. and P. B.'s *communications on railway curves must stand over for the present, as we have already devoted so much space to that subject.*

Design of Huddersfield College by J. P. Pritchet, *architect, will appear in an early number.*

* —— *We shall be glad to receive his proffered communication, we cannot hear from him too often.*

H.'s *design has appeared in another publication.*

Report on the plans for preventing accidents on board of steam vessels, and Dr. Charles Schafhaeutel's report on Playfair's boiler will be noticed next month.

To our correspondent at New York we return many thanks for his exertions on our behalf.

We are happy to find by the numerous letters we have received that our advocacy in the cause of Steam Navigation meets with the approbation of our subscribers.

We recommend a correspondent, his signature we forget, to read the Fable of the Miller.

Δ *We are obliged for his letter, we have long been aware of the sinister working of the individual alluded to—he is too contemptible for our notice, "every dog has his day." We feel ourselves independent of all parties.*

The Cinque Ports *reply to our correspondent* E. *on the recessions and encroachments of the sea will appear next month, together with a communication from* NOTA, *on the same subject.*

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No. 11, Parliament Street, Westminster.*

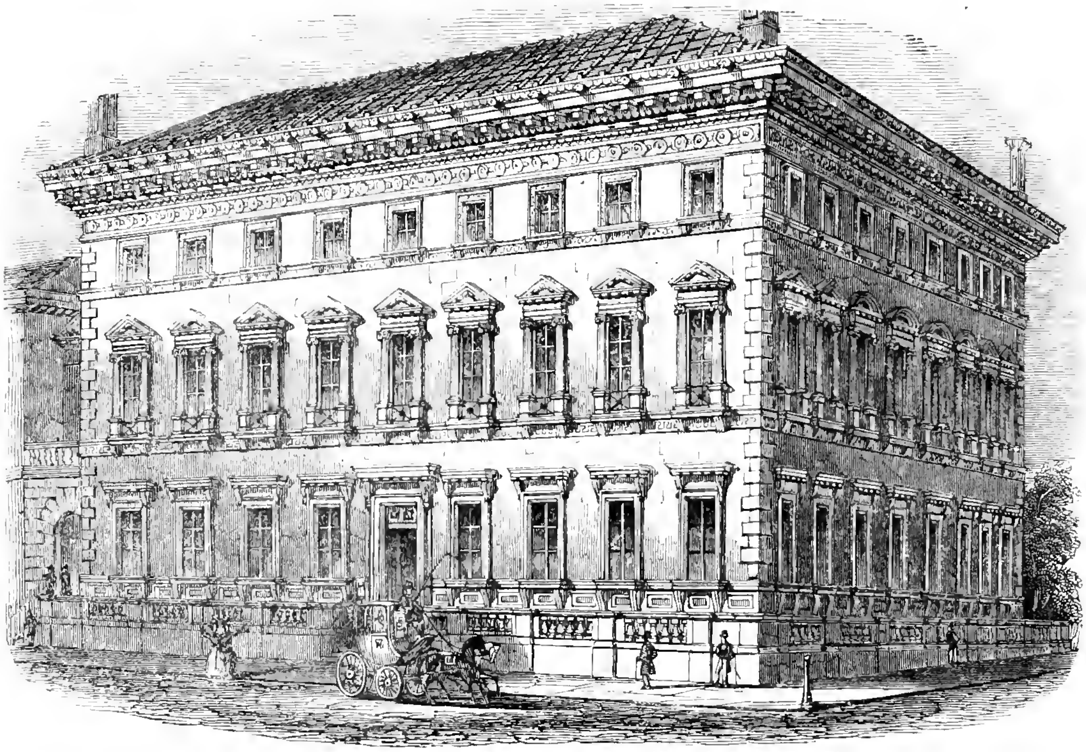
Books for review must be sent early in the month, communications on or before the 20th (if with wood-cuts, earlier), and advertisements on or before the 25th instant.

The First Volume may be had, bound in cloth and lettered in gold, Price 17s.

*** The Second Volume may also be had, Price 20s.

THE REFORM CLUB-HOUSE, PALL MALL.

CHARLES BARRY, R.A., ARCHITECT.



What can be said about club-houses? Their friends are silenced by their success, and their enemies cannot contend against them. Hercules might have given up his club, but the aristocracy are determined not to follow his example. Their merits and demerits are beyond our control,—one only fact we have to deal with, and that is their rapid increase. The palaces have disappeared or have been eclipsed, and the south of Pall Mall is covered with an almost uninterrupted line of temples in honour of the social principle. If the grandeur of our commercial edifices strikes the foreigner with wonder, or if he considers our parks and squares as worthy rivals of his alleys of orange trees, how can he fail to pass without notice these personifications of national characteristics. The foreigner may justly marvel to see the palace eclipsed before the shrine of Mammon, but he must be still more astonished to see the hospital front of St. James's shrinking back from the grandeur of its unroyal neighbours. The principle of association is the foundation of civilization, and the English race are influenced by it more than any other. We are Napoleon's nation of shopkeepers, mechanics and stock-jobbers to the fullest extent, who take out our amusements in shares, and raise a joint fund to provide domestic comfort. Pall Mall is the true House of Commons of the nation—here every political principle is represented, and every shade of society has its point of reunion. In this street of palaces, unique in Europe, one of the most striking is the subject of our present notice.

For the view of this building we are indebted to the *Literary World*, of whose embellishments it may be considered a very fair specimen,—one certainly greatly superior to any thing to be met with in similar publications. With regard to the structure itself, we shall not now attempt to enter into any architectural description of it, reserving such notice till we have the opportunity of rendering it complete; and shall therefore at present only observe that the Reform Clubhouse is the most perfect and imposing specimen of Italian architecture in the metropolis,—reserving, however, to ourselves, our admiration for the Garden-façade of the Travellers, as the most elegant and piquant example of that style, upon a lesser scale. In this new work of Mr. Barry's we perceive extreme simplicity and unity of design combined with a very unusual degree of richness,—an *astylar* (columnless,) with more of architectural expression than is generally produced by a display of columns forming a principal order. The breadth of the piers or spaces between the windows contributes not a little to that repose which is so essential to simplicity, and hardly less so to stateliness. The string courses are particularly beautiful parts in the design, while the cornicione gives an extraordinary air of majesty and grandeur to the whole.

It is the largest and most commodious of any of the club-houses in the metropolis: the length of the front is 120 feet, exclusive of the entrance between the Travellers' Club-house and the main building, which is fifteen; making, in all, a frontage of 135 feet. The depth of the main building is 104 ft. 6 in.; the height of the cornice from the pavement, is about sixty-eight feet.

The roof is covered with Italian tiles, manufactured expressly for this building, by Messrs. Rutledge and Keene, of the Belvedere road. The whole of the building is faced with Portland stone, it is a very fine specimen of masonry, and does credit to the contractors, Messrs. Grisell and Peto. We must not omit to mention the scientific manner in which the building was erected; a scaffolding of considerable strength was constructed of timber, and on the top was laid a railway, upon which was worked a traversing crane that could be moved along the building either longitudinally or transversely: by this means the stones were raised from the ground and placed on the wall with very little labour to the mason, who only had to adjust the bed and lay the stone. We perceive that Messrs. Grisell and Peto are about to adopt the same plan for the new Houses of Parliament, by which means they will save very considerably in the price of labour.

BRODERIP'S TROUGH OR TRUNK ENGINE.

Fig. 1.—Section.

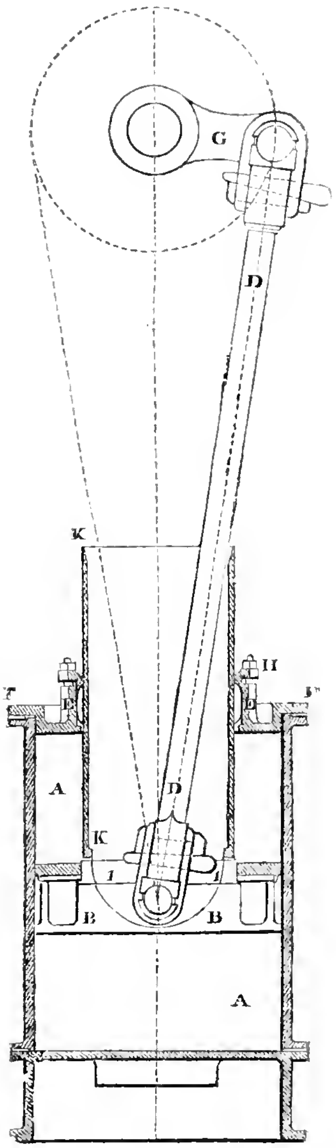


Fig. 2.—Section of Casing and Centre.

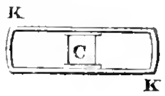


In consequence of the late discussion at the meeting of the Great Western Steam Ship Company at Bristol, relative to the intended introduction of "Humphrys' Patent Trunk Steam Engine," for the new iron steam ship now building at Bristol. We felt desirous of obtaining a drawing and some particulars relative to it: upon making enquiries among our scientific friends, we were much surprised to find that a similar engine had been patented by another party nearly seven years antecedent to the patent of Mr. Humphrys; and was invented by the late Mr. Charles Broderip of Spring Gardens, a gentleman who was well known to the scientific world as a clever engineer and scientific man. Upwards of eighteen years ago he equipped a steam vessel called the "Tartar," with which he made a voyage into the Bay of Biscay and back, and by this spirited proceeding was the first person to demonstrate the practicability of sending steam vessels across that tempestuous bay, which, till then, had never been attempted.

He afterwards invented the application of a casing or trunk attached to the piston, by the use of which, he was enabled to connect the piston rod with the crank direct, as shewn in the accompanying drawing; he, however, died shortly afterwards, and his executor Col. D'Arcy took out letters patent for the invention, dated Nov. 29th, 1828, and a sketch and description of it appeared in a scientific work called the "Journal of Arts" shortly afterwards.

Some years afterwards, viz., on the 28th March, 1835, Mr. Francis Humphrys again patented, identically the same arrangement of the steam engine, and subsequently proceeded to make a pair of engines on this principle, that were fitted to a steam vessel called the "Dartford" which ran for a short time, but which it is stated, have since failed in the cylinders by the angular friction of the pistons. We shall now proceed to give a description of the engine as specified by both parties, and then leave it to our readers to judge how far Mr. Humphrys is entitled to his patent, or can be considered as the *original inventor*, for if there be any merit in the invention, it is only right that the saddle should be placed on the right horse.

The following description we extract from the specification of the patent granted to Col. D'Arcy:—The specification describes other improvements besides the one in question; one of them was for a *sliding stuffing box*, "the piston rod connected at one end to the piston, and at the other end to the crank of the engine without the intervention of any cross head, side rods, guide frame or parallel motion to keep the piston in a perpendicular position whilst it is ascending and descending in the cylinder, the improved method of connecting the piston of any cylinder used in a steam engine to its rod is by means of any convenient joint, or by a ball and socket which will allow the piston rod to oscillate or yield to the motion of its crank without altering the vertical or horizontal position of the piston, whilst acting either in a cylinder placed vertically or horizontally as circumstances may require; and by the introduction of the sliding stuffing box, I am enabled to apply the oscillating piston." The specification then proceeds to describe this invention by a reference to the drawings accompanying the specification. A A the cylinder, B B the piston, C C the centre of the joint of piston into which the joint of the piston rod D D is fitted and united; D D shows the rod forming its greatest angle by the motion of the crank G; E E the sliding stuffing box working in grooves, rabets or dovetails, made perfectly air and steam tight, and placed securely on the top of the cylinder cover F F. Instead of the sliding stuffing box, the patentee in some cases substitutes "*the trough or socket* K K" (showed in the annexed engravings) "firmly connected to the piston, and which trough or socket must be made hollow and of sufficient capacity to allow the piston rod D D to oscillate freely in its width, thickness, and area, so that in its transverse, through the fixed stuffing box E E, and by the gland H, the trough or socket K K may be rendered as securely air and steam tight in its connection with the cylinder A A, as if it was a cylindrical piston rod."

We shall now give some extracts from the specification of the patent granted to *Mr. Francis Humphrys*: we did not consider it necessary to give a drawing, as it is so identically like the above.

The letters in italics within parenthesis, we have introduced, they refer to the above engraving; the other letters are as they appear in Mr. Humphry's specification. "A A is the cylinder, B B the working piston, C (*G*) the crank, D D (*K K*) a steam tight casing or trunk of a rectangular form rounded at each end, which is permanently attached to the piston in such a manner that the axis of the one shall correspond exactly with the axis of the other, and which casing works up and down with the piston, E E (*F F*) is the lid or cover of the cylinder A A, G G (*E E*) the stuffing box which is made to fit the outside of the casing or trunk D D (*K K*) instead of as usual fitting the piston rod." In the concluding part of the specification, Mr. Humphrys states "that what I claim as my invention is the addition, to the pistons of steam engines, of a steam tight casing or trunk permanently affixed thereto, and working up and down therewith, and the employment of a connecting rod passing from the working piston to the crank through such steam tight casing or trunk, both in the same manner herein before specified; by means of which contrivance, the reciprocating motion of the pistons is resolved into a rotary motion without the intervention of the beams, cross heads and other auxiliary appendages in common use."

MEDIEVAL ARCHITECTURE IN FRANCE.—No. I.

Whatever may be the opinions of individuals with regard to the merits of the Gothic style, it has so strong a hold on our sympathies, and so many advocates and supporters, that it can neither be neglected in a professional point of view, nor be decried as unimportant. As a branch of instruction its study is imperative, nor is it less so as coming within the domain of the antiquarian and the artist. Linking us, as this style does, in a common bond with surrounding nations, abounding in monuments not merely of local but of universal interest, its history in other countries affords not only pleasure, but becomes of value as tending to illustrate its progress here. To no other country does this apply more strongly than to France, where the architectural associations, like the political relations of the country for many centuries were interwoven with our own, springing from the same parent stock, and from time to time forming alliances which tended to keep up the mutual connection. At the same time the later and closer connection of France with the lower empire both in the east and the west has given rise to modifications which either never existed here, or of which the vestiges have become extinct, as in the case of the Romanesque and Byzantine Gothic, of which monuments are to be found there replete with the highest interest. It is for these reasons therefore that as we know that it would be acceptable to our readers we are induced to profit by the present opportunities afforded by French periodicals and other authorities of presenting a short account of the French Medieval styles in a familiar form.

In our second volume, page 193, will be found a valuable paper by Mr. Poynter, on the comparative chronology of English and French medieval architecture, founded on the investigations of M. Comon, of the Antiquarian Society of Caen.

COMPARATIVE CHRONOLOGY OF FRENCH AND ENGLISH MEDIEVAL ARCHITECTURE.

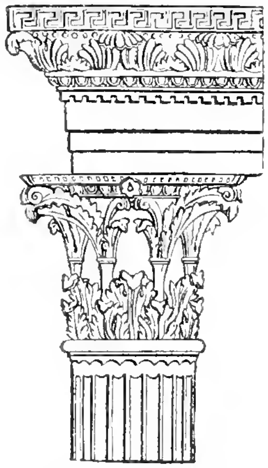
	950	Romanesque.	
	1000		
	1050		
Norman . . .	1100	Transition.	
	1150		
Early English . .	1200	Primordial Gothic.	
	1250		
Decorated English .	1300	1st epoch.	Secondary or Gothique Rayonnant.
	1350	2d epoch.	
Perpendicular . .	1400		
	1450	1st epoch.	Tertiary or Gothique Flamboyant.
	1500	2d epoch.	
	1550		

Taking this as our basis, the first style to which our attention is directed is the Romanesque, a style of which we have no example in this country.

THE ROMANESQUE STYLE.

Applying the term of Romanesque style to those monuments imitated more directly from Roman architecture, we find a variety of specimens erected between the fifth and twelfth centuries bearing all the impress of their origin, and throwing much light on the history of the art. It was only about the fifth century after several invasions of the barbarous hordes, that sufficient tranquillity was restored in France to allow of the erection of new edifices, and of the repair of the old ones. The conversion of the Franks under Clovis to Christianity, created a necessity for buildings suitable to the new form of worship, to which the Roman temples were ill adapted. Instead of narrow sanctuaries secured by thick walls, the ceremonies of Christianity required large covered buildings, in which the congregation could participate in the services. It seems that under these circumstances the architects of that period sought for the type of their designs in the ancient synagogues of the Jews, and the civil basilicas of the Greeks and Romans. To the former they were naturally led by tradition and association, while in the latter they found a conveniency of disposition suitable to the extended wants of large communities. Thus were the caves in which the early Christian sought refuge, supplanted by the new edifices which from being built at Constantinople and Rome, served as models to other Christian countries. Hiding from persecution it was only in caves and in the hollows of rocks that the first votaries could worship in peace, and yet even in these places of banishment they had already introduced greater pretension in the disposition. At Montmajour, near Arles, one grotto church is laid out with two parallel naves, while in that fine specimen of a primitive temple at Sutrium, in Etruria, the space formed in the rock is divided into a vestibule, a nave divided by pillars so as to form side aisles, and a sanctuary. With greater liberty of worship more display was aimed at, and rude attempts were made to rival the labours of the past. In these essays it was natural that the relics of Roman art should be referred to as models, and plundered for materials, although as they could neither appropriate Roman genius nor transfer Roman skill, they necessarily fell behind their masters in success. Who can mistake the source, whence the annexed entablature and capital is derived, and many as strong can be adduced. Thus also the details of the order in the porch

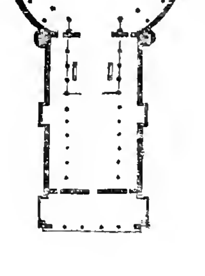
Fig. 1.



of the Cathedral at Avignon, the Franks employed not only bricks similar in form to those of the Romans, but used those which they obtained from the destruction of other edifices.

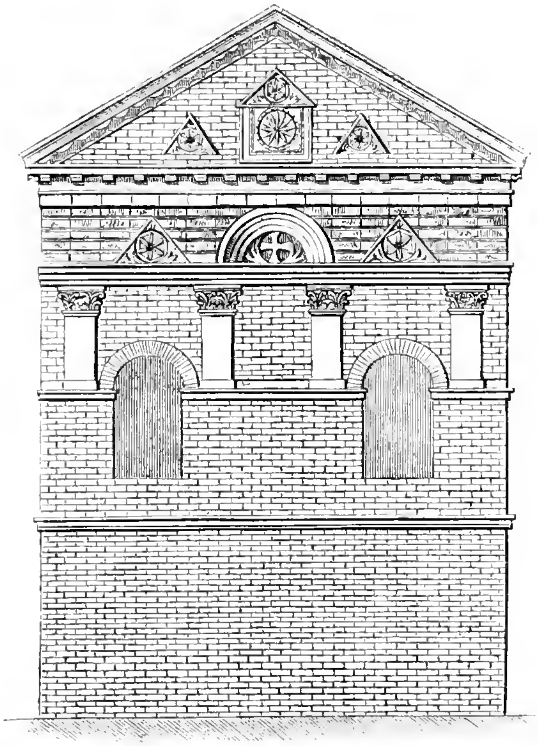
The ground plan of the Romanesque edifices is evidently referable to the sources already alluded to, and we have in Fortunatus, a poet of the sixth century, and Gregory of Tours descriptions of several churches which serve to confirm this to the utmost extent. Such were the primitive basilicas erected in Paris, Tours, Clermont and other cities of Gaul. We find that they were spacious, of an oblong form, divided into several naves by rows of columns of marble, doubtless obtained from the pagan spoils, and arranged parallelly to the lateral walls. At the hemicycle in the end, used as a sanctuary, was placed the altar, in the position called in Vitruvius the tribune, which in Christian edifices was always single, or at one end only, while in those of an earlier period, as in the basilica of the Foro Trajano at Rome, a tribune was occasionally placed at each end. Of the early specimens of the Christian basilica, if we may so term it, one of the best preserved, is that of the Cathedral of Parenzo in Istria, built in the sixth century. Frequently however these buildings were of a circular form, many of which are to be found in Italy, while in France there is St. Germain l'Auxerrois, called St. Germain the Round: several were consecrated by Constantine, both in the east and the west. Occasionally the circular form was combined with square naves, of the kind before described, something in the style of the church of the Holy Sepulchre. The church built by Perpetuus over the tomb of St. Martin, near Tours, was a fine example of this last combination, and the accompanying engraving shows a restoration of the ground plan from the description of Gregory, of Tours.

Fig. 2.



The mode of construction was based on that of the Romans, the buildings being made either of Roman brick or as before observed of bricks of a similar form made at that time. The architects also frequently made use of brick and stone in conjunction, a favourite system with the Romans. This is the case with the Baptistry of Poitiers, and the church of the Basse Œuvre, at Beauvais. Although at first formed very simply, these buildings soon began to be richly decorated with gilt mosaics, splendid marbles, and luxuriant carvings. Stephen of Tournay describes the basilica of St. Genevieve at Paris, built by Clovis, and destroyed by the Normans, as being covered with mosaics both inside and out; and Fortunatus, calls the basilica of St. Germain des Prés, built by Childebert, the gilt house of Germain, being decorated with gilt mosaics, and with a bright metal roof.

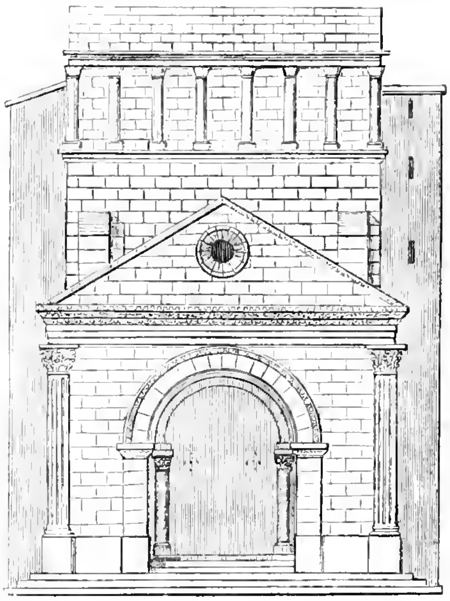
Fig. 3.



The church of St. John at Poitiers, represented above, is considered as belonging to the sixth or seventh century, and was originally a baptistry, as is proved by the discovery of a great octagon basin in the centre, and used for baptism by immersion. This building has undergone many changes, but the genuine portion is sufficiently distinct to be easily recognized. A pediment of ancient proportions surmounts the façade, and mouldings of simple profile frame it in, and these corresponding to the pitch of the roof, are accompanied by incrustations of a semicircular shape. Large stones, cut in intaglio, and ornamented with rosettes, decorate the tympanum. The horizontal entablature which supports the pediment is complete, consisting of an architrave, frieze and cornice, which last is enriched with modillions. Below the entablature is a band or zone, formed of large stones and bricks placed alternately, in the midst is an arch composed of several concentric circles, projecting over each other; and in the centre of this arch is a Greek cross resting on an architrave, supported by short pilasters with capitals in the ancient style. Two triangles in stone, similar to those in the tympanum, are on the right and left of the arch. Between the pilasters and below their bases are two windows now circular, but which were formerly in the shape of arcades, lighting the interior. A string course divides the lower part of the front into two equal divisions, through which no door was made, as it was opposite to the entrance.

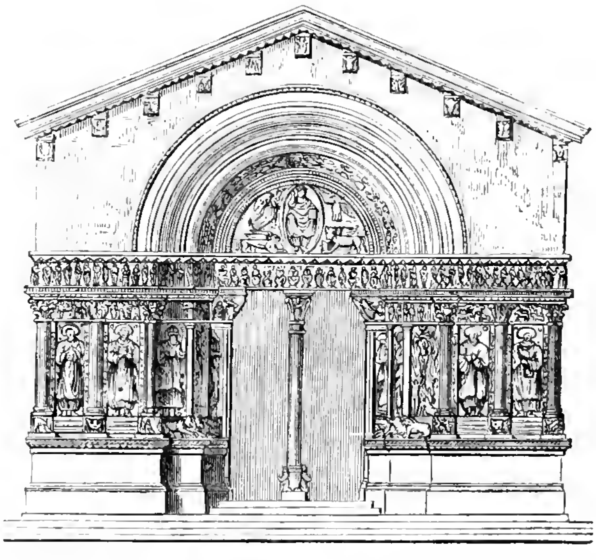
The buildings of the south of France belonging to this period wear more of the ancient physiognomy than those elsewhere, a circumstance to be attributed to the neighbourhood of the noble Roman ruins, many of which still exist. The Cathedral of Our Lady of Gifts, at Avignon, has a porch the date of which is not well known, but which may be referred to the eleventh century, from the introduction of the door of the church at the bottom, and from the situation of the steeple, which surmounts it. This porch carries a pediment, of which the pitch is still

Fig. 4.—Portal of the 11th century, of Our Lady of Gifts, the Cathedral of Avignon.



conformable to ancient tradition; the mouldings of the side cornices have disappeared; in the middle is a circular opening called by the Christian authors an *oculus* or eye. The pediment is supported by an entablature of bad proportions, but ornamented with details servilely imitated from Roman architecture. The entablature rests on two Corinthian columns, attached to the angles of the porch, shown in our first engraving, and so exactly imitating the Roman monuments in the country, as to lead at first view to the belief that they are of pagan origin. In fact the arcade like entry shows a great resemblance to those of the triumphal arches of Orange and St. Remy. The basement of the steeple is decorated with a row of columns quite in the Roman style.

Fig. 5.—Church of St. Trophime, at Arles.



In the beginning of the twelfth century was erected the beautiful church of St. Trophimus, at Arles, represented above, and which seems a point of union between the Roman style and that of the middle ages proper. According to Gregory of Tours, this church, which in the sixth century was consecrated to St. Stephen, was only named after St. Trophimus in 1152, when the relics of the first bishop of Arles were placed in it. In the fifth century, this cathedral had been enriched with marbles from the theatre of Arles, which Saint Hilary had used for the decoration of Christian places of worship. It is surmounted by a pediment very slightly inclined, and the mouldings with which it is enriched, like most of the others in different parts of the porch, are still in the Roman style. Several details recall the traditions of the past, but already the representation of singular figures, capitals and bases, decorated with lions and chimeras, showed that the imagination of Christian artists was wandering from the rules laid down by the Greeks. Sacred history, related in sculpture, begins to cover all the zones of the façade, and images banished from the inside of the church take their stand without. In the midst of the tympanum formed by the springing of the arches, is God the Father surrounded by emblems of the Evangelists, above on the lintel are represented the Apostles, on the right of the Almighty the elect, and on the left the damned. Between the columns of marble which decorate the anterior parts of the door, are carved saints and bishops, a resurrection and other religious subjects. It may be observed that the arch already begins to assume something of the pointed shape, which it was afterwards to retain so long. The cloister of the church of St. Trophimus is one of the finest known; the arcades of its porticoes are supported by light columns surmounted with capitals of good style, and all the jutting columns which form the principal divisions of the galleries are decorated with statues of life-size, and with numerous bas reliefs, producing an admirable effect. Though the galleries of the cloister are of the same period as the portal, the other two are of the fifteenth century.

At Vaison, at the foot of Mount Ventoux, at Cavaillon, at Pontoise, at St. Paul-trois-Châteaux, and in many other towns of the south of France, are to be seen churches or chapels, in which it is easy to perceive that in the middle ages was formed a school of architecture, for a long time imbued with the ancient principles. If we add that in the royal church of St. Denis, founded in the fifth century by Saint Genevieve, and at Montmartre, where was a chapel dedicated to St. Denis are to be found marble capitals, decorated with the cross and other Christian emblems, and yet executed in the form and with the character of Roman capitals, it may be believed with good reason that the primitive churches of the Gauls showed like those of Italy, a filiation with Roman art, and that the tradition of classic forms was only lost after a certain number of generations, and through the influence of Byzantine, art imported from the east. At the same time we are able to trace the germs of the subsequent styles, for in Anvergne, Baron Taylor* found in a church of the Romanesque era, the arch decorated with the chevron moulding.

HARBOURS OF REFUGE.

Practical Observations on Harbours of Refuge, and on the effect of Back Waters or Sluices, as applied in the Scouring of Harbours.

By H. Barrett.

"Give harbour room, and public ways extend,
Let temples worthy of our God ascend,
Bid the broad arch the dangerous flood restrain,
The Mole projected break the roaring main,
Back to its bound the subject sea command,
And roll obedient rivers through the land."
Cherbourg.

The subject of our harbours having for some time attracted much attention, and the recent appointment of Commissioners to investigate and report upon the state of the harbours on the south-east coast, having given rise to some discussion as to the proper principles which should govern the construction of harbours generally, I am induced to offer the following remarks as the result of my own experience and observation on this subject, continued through many years and in various parts of the world.

In 1826, and again in 1827, I was examined before a committee of the House of Commons on the subject of the then proposed harbour of refuge at Lowestoft, the connexion of the sea with Lake Lothing, and the improvement of the natural *river navigation* from thence to Norwich, for vessels drawing 12 feet water, so as to make that city a port *via* Lowestoft, and avoid the necessity of transhipment at the port into river lighters, as at Yarmouth, through which means Norwich has been for centuries supplied with coals and other sea-borne merchandize.

The following are extracts from the evidence given before the Committee on the occasion I have referred to, viz.

From the evidence of the Engineer.

"My proposition is to carry 12 feet at low water into the Lake, and I have no doubt on the outside it will scour deeper.

* Journal, vol. 2, p. 194.

Q. You will always have 12 feet into the Lake?

A. Yes.

Q. What will the depths be at high water?

A. 20 feet. A vessel of 16 feet could enter during two thirds of the tide, *i. e.* at two thirds ebb.

Mr. Telford.

Q. Can you form an opinion as to the distance it will be from the shore where the bar will form?

A. There will be no bar—no deposit—next to none.

Q. Will the water from Lake Lothing take it away?

A. Yes; but I say there will be *no bar*, by this operation of the water, *none at all.*

Mr. Barrett.

Q. Do you think the sand carried out of the harbour would be lodged on the flat and form a bar?

A. Yes, and that it would lodge beyond the reach of the scouring water of the Lake.

Q. Then you think that an accumulation would take place?

A. I am decidedly of an opinion that an accumulation would occur, in the shape of a bar across the Harbour, and that at low tides even small vessels could not enter in consequence of the accumulation."

On my second examination before the Committee of the House of Commons, which was in 1827, the following questions and answers occurred, viz.

"*Q.* You have a clear opinion that a bar will be formed?

A. That *is* my opinion, and that the sluicing power will increase the evil.

Q. You have adopted a new hypothesis on the subject of a bar?

A. I have, and differ with all the engineers as to the cause of bars.

[See published evidence on the Norwich and Lowestoft Navigation, in sessions 1826 and 1827.]

The Act of Parliament having been obtained in 1827, the works of the Harbour were proceeded with, and in 1831 the Lake was connected with the sea; the sluices were then applied in order to scour out the newly excavated passage; but the immediate effect after a very few sluicings, was the formation of a *bar* opposite to the newly made entrance, the result being just as I had, in my evidence before the committees, stated it would be; and instead of 12 feet at low tide, and 20 feet at high tide at the entrance, according to the engineers' previous opinion as shown in their evidence, the result was that it became *nearly dry* at low tide, so that no vessels could enter. Such was the injurious consequence of the sluicing water.

In 1832, after the effects of the sluicing had been developed, a remonstrance was addressed by letter to the directors of the Harbour, by pilots and others residing at Lowestoft, in which they said,

"Deeply sensible of the advantages, national as well as local, attainable by the construction of an efficient harbour, at Lowestoft, we cannot but view the present with a feeling of regret, *its entrance encumbered with a shoal or bar.* We understand that the Commissioners for the Public Works are willing to lend £50,000 on mortgage, and we strongly recommend the appointment of an *experienced nautical engineer.*"

From the fatal error in the use of the sluicing waters, added to the mistaken mode of construction adopted, the whole undertaking became a failure, and the entire property, with piers, wharfs, buildings, engines, &c., have been recently submitted to public auction by the loan commissioners as mortgagees for £50,000 advanced by them; but the Harbour and all the property which had cost about £140,000, would not fetch £15,000, and were consequently bought in.

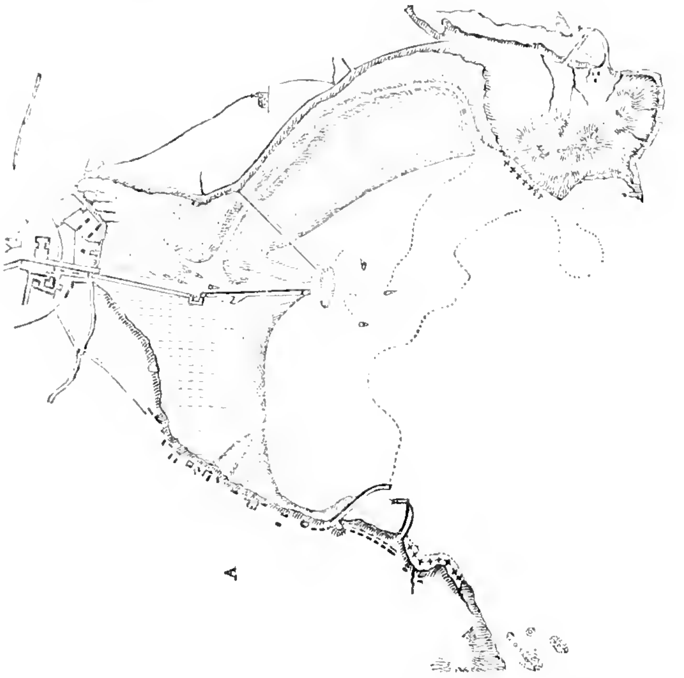
As far back as the year 1823, I published a pamphlet admonishing the public that it was impossible to construct a harbour of refuge on the site and by the method then proposed, and afterwards adopted; the result of this undertaking has fully verified my predictions, which, indeed, were founded on infallible data. Some time prior to that period, and before I developed my opinions on the certain effects of egress or sluicing waters, I had visited and observed upon various harbours in different parts of Europe, viz. St. Petersburgh, Nerve, Revel, Dantzick, Konnigsberg, Copenhagen, Elsineur, Norway, Hamburg, Tonningen, Amsterdam, Rotterdam, Ostend, Brest, Bayonne, Cadiz, Gibraltar, Malta, and on the coast of Africa; also many ports in England, Ireland, and Scotland, Shetland Islands, and the Orkneys.

In none of those places did I find any exception to the thesis which I have adopted relative to the injurious effects of egress, sluicing, or scouring waters, and I venture boldly to assert that in no part of the globe is there any exception, viz.

"*That wherever the water passes from the interior into the ocean with sufficient velocity to carry matter in suspension, and to cause a conflict-*

ing action with the waters of the sea, there a shoal or bar is invariably formed, and that the greater the velocity of the egress water, the larger will be the accumulation of shoal or bar. (See Fig. 1.)

Fig. 1.—Plan of Dublin Bay and Kingstown Harbour.



In various parts of the world, harbours at the entrance of rivers have been entirely blocked up and lost, by the operation of sluicing waters, and whether naturally, or artificially applied, the effects are similar. I may instance the following places, viz.

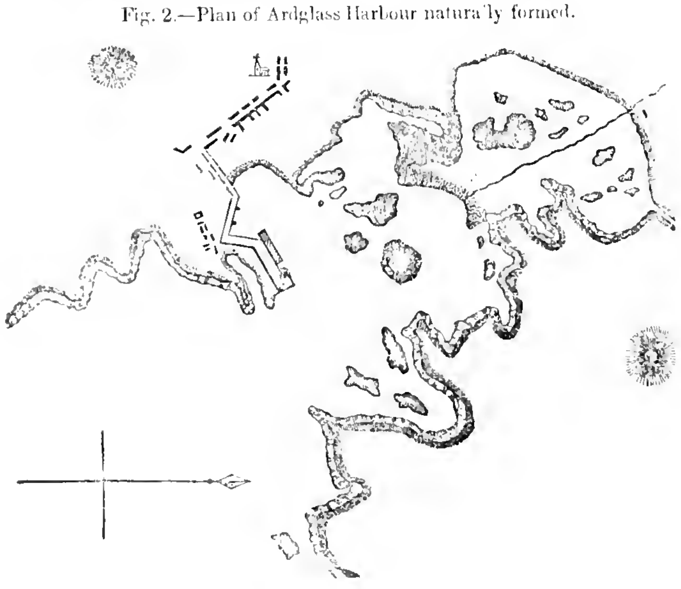
Wisbeach, Yarmouth (its north entrance), Winchelsea, Romney, Lowestoft, before referred to, Alexandria, the mouth of the Po, and of the Nile, and many others which might be enumerated.

The learned and great geologist, Baron Cuvier, states that "all attempts to improve the entrance to harbours by scouring waters have ever proved abortive, and brought science into contempt."

The futility of such attempts the examples here quoted demonstrate.

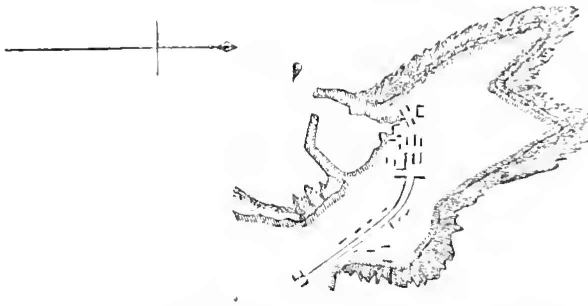
Labelye, who wrote in 1747, said, "*I advise all persons to be on their guard in attempts to construct locks or sluices on coasts, for besides the expence, they would be in danger of losing their harbours.*

Fig. 2.—Plan of Ardglass Harbour naturally formed.



My second proposition is that, "*wherever there is an absence of egress or sluicing waters, or where the water passes into the ocean so as not to convey matter in suspension, and not to cause a conflicting action with the waters of the ocean, there is no bar or shoal, or exterior accumulation;* and this proposition also applies equally to a natural harbour (see Fig. 2.) as it does to one of artificial construction. (See Fig. 3.)

Fig. 3.—Plan of Portrush Harbour, artificially formed.



Among the places I have visited, there are many that exemplify this proposition, the harbours being free from bars, and some of them sufficiently capacious to contain the whole British navy.

I will now refer to the evidence taken before a Committee of the House of Commons in 1836, on Dover Harbour, and on the means suggested by the Engineer for improving that harbour, who, in his evidence, says, "we are putting down pipes; and that is to carry away the *sluicing water*, and render it *more available by increasing its force*. The object has been that which every engineer who has been consulted is desirous to obtain, and it appears to me that *the remedy, although an expensive one, cannot fail to be complete.*"

Mr. Cubitt, (in answer to a question by the committee), said,

"Suppose that these works do not do so much as it is expected, for *successful they must be to a great degree*—"

The attempted improvement has turned out a failure. I will next give a short extract from the evidence of nautical and practical men, who were examined by the same Committee, and the result has shown that their opinions were better founded.

Mr. Hammond, a pilot, speaking of the plans, stated the alteration which had been made had not been effectual.

"*Q.* State your opinion to the Committee on the works now going on.

A. The bar will be more prejudicial and dangerous than it was before. If cleared one tide, it will be filled up the next.

Capt. Boxer, R.N., gave similar evidence, and said, "the works *will be a complete failure.*

The Honourable Captain (now Rear Admiral,) Elliot, gave similar evidence, and said, "*I consider, if the whole of the present plan was completed, the Harbour, as far as regards a Refuge Harbour, would be just as imperfect as it is at this moment.*" *

After reading the above evidence, it must be clear to every candid and reasoning mind, that whatever the right plan may be for the construction and improvement of harbours, that plan has not yet been hit upon by those engineers who have hitherto employed their talents in this department, and as the greatest national interests are involved in the question, and the safety and protection of our great maritime commerce, as, indeed, of our naval force itself, must mainly depend on the efficiency of Harbours, in which ready refuge may be found in time of need, no object can possess a higher claim upon public attention than Harbours of Refuge; on almost every part of our coasts the loss of property and of human lives have become a reflection on our national character. It is a lamentable truth, that while so many schemes of improvement or benevolence are daily attracting the patronage of the people of this kingdom, yet both the enterprize and the humanity of the same people have lain comparatively dormant on this subject, which more than any other affects our character and our interests as a great maritime nation.

In this branch of practical knowledge we are, it is to be regretted, much behind our continental neighbours, and prejudiciously shall we find it so in the event of a war with them.

In the session of 1839 I presented a petition to the House of Commons, praying to be heard by a committee on the subject of bars, and on the mode of constructing Harbours, free of bar or shoal at the entrance, and I was prepared to prove that the want of practical and nautical engineers was the principal cause of failure of the attempts

* See the published evidence on Dover Harbour. Session, 1836.

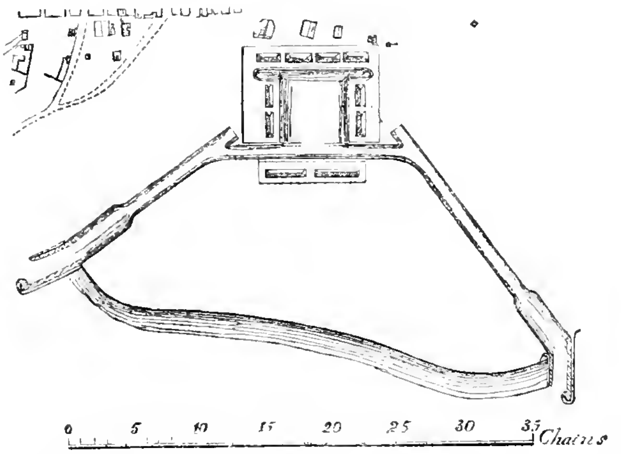
to construct eligible Harbours, or of improving the existing Harbours, and further experience has strengthened this opinion.

The petition was merely laid on the table, and my earnest desire to engage the attention of Parliament and of the public to a subject so deeply important, was on that occasion disappointed.

I am, however, not discouraged in my hope of ultimate success in the promulgation of my opinions, in which I have now the gratification to find myself countenanced by scientific, practical, and nautical men; and I shall continue to use my zealous exertions in pressing upon the public attention the necessity of full discussion to ascertain, and when ascertained to adopt and pursue, what may prove to be the correct principle of constructing and maintaining Harbours of Refuge, with regard to which I repeat my firm conviction of the *great error*, which cannot be too generally exposed, of the application of *sluicing waters for the purpose of improving the entrance to Harbours*, at best but a *temporary expedient*, and which has never proved a *permanent remedy*.

To the investigation of this subject I would especially, and most earnestly, invite those eminent and humane individuals who are bestowing their wealth, and influence in promoting charities, for the relief of the widow and orphans of shipwrecked mariners, and remind them of the old adage, "that prevention is better than cure;" that it is better to *save the lives of sailors*, than to stand by and see them *perish*, and then provide for their families who may be left destitute, and that Harbours of Refuge would be the means of preventing many of those calamities, no one can entertain a doubt; and that such Harbours can be successfully constructed in various places on our coast, where they are so much required, I will venture with confidence to affirm. (See Fig. 4.)

Fig. 4.—Plan for a Harbour of Refuge.



A Committee of the House of Commons was appointed in the session of 1836, for inquiring into the causes of shipwrecks, and they reported,

"That three millions of property, and one thousand human lives, are annually lost by shipwrecks on our coasts; and that the *want of efficient Harbours of Refuge* was one of the principal causes of these calamities.

The Committee of the General Ship Owners' Society, in their report, May, 1837, referring to the above report, stated that there is no Harbour of Refuge (that can be so called) from *the Firth of Forth to the Thames*,* and that the numerous casualties, unfortunately occurring in the navigation of the seas surrounding the British coast, naturally awaken the feelings of humanity; and that the loss of property from the River Tyne (only), amounted *annually* to £151,222, and of human lives in the same time, 170.

In 1836 there were 110 vessels stranded and wrecked on the Lowestoft and Yarmouth coast, and 197 vessels lost anchors and cables, many others sustained much damage. These losses (alone) may be estimated at £120,000, all of which falls on the ship owner or underwriter; but the incidental expences of a voyage, Harbour dues, &c., together with the ship-owners' profits, are paid by the *consumers* of the cargoes in the shape of freight.

The above sum would be sufficient to construct an eligible Harbour of Refuge on that coast; and the £3,000,000 annually lost by shipwreck, is adequate to construct Harbours on various parts of the coast, where they are so much required.

* Nor is there from the Thames to the Isle of Wight.

Under the impression, therefore, that Harbours of Refuge can be constructed, and ought to be constructed, I would invite the active assistance of all who can lend a hand in so good a work, for the attainment of which, I shall continue to devote my best exertions, myself *an old sailor*, I would, on behalf of sailors and their dependents, and for their safety, invite in so sacred a cause, the co-operation of the benevolent, the patriot, and the Christian.

H. Barrett.

London, 8th April, 1840.

TABLE OF ARCHITECTS.

[A NOTE TO THE EDITOR.]

Sir—I am quite horrified at finding that you have made me commit homicide—I might say infanticide, sending Schinkel out of the world, as soon as he had come into it. I don't say your printer's devil, but your devil of a printer, has *diabolically* and with malice prepense omitted the word "*born*" attached to the name, consequently it now appears that I fancy Schinkel died in the year 1781, whereas he is not only alive and well, but doing well as may be seen by your "Literary Intelligence" at page 130; and I hope he will not appear in any obituary or necrology for many years to come—not until 1881, at which time he will be only one year older than Clerisseau was at the time of his death; the latter architect having attained a degree of longevity far exceeding that of any other whose name occurs in the table.

In a paragraph of page 132, some computations are made from the table relative to length of life among architects, but it is not stated how many lived to upwards of 80. Among the latter was Gondouin, who, though he did not attain to a very remarkable longevity, is remarkable for having ventured to commit matrimony with a girl of seventeen, at the venerable age of seventy-seven!

I have not yet done, for I must protest against the appearance of a gentleman called Jean Radolphe, whom I never invited to my *table*, and who must therefore be turned out as an intruder. Perhaps he may be an acquaintance of your *diabolical*; and that worthy may be able to give some account of him. The first Jean appears, in fact, to be a mere nobody,—and so also does Gerstenburgh of whom it should have been recorded that he was professor of Civil Architecture at Jeva, and author of several publications, but principally on surveying; and, therefore, has but little right to make his appearance among the company he does.

And now feel relieved: you may, therefore, present my hearty, if not good wishes to your dial, and believe me, &c.

W. H. L.

P.S.—I have just seen by a foreign journal that Albertolli, whose name stands at the end ot the table died last November, in his 98th year, consequently may be quoted as an instance of longevity. I also now perceive that Jean Radolphe, should have been attached to the name of Perronet, in the next line.

Sir—Among the Architects of the 18th century, a list of eleven was given in your last number; the Signor Albertolli was mentioned, the author not being sure whether he still existed. I received, a few weeks since, a letter dated 27th January last from his nephew and son-in-law the Signor Ferdinando Albertolli, professor of architectural ornament in the academy of Breva, and honorary and corresponding member of the Royal Institute of British Architects. In this letter is the following paragraph:—"To our great grief we lost, on the 15th November last, our venerable parent at the age of 97 years, three months and 21 days, from a cold in the chest. His best work is the Villa Melzi on the lake of Como, and he was the author of several publications on ornament. Our academy are now raising a subscription in order to erect a handsome monument to his memory."

I regret that the author of the list, to which I allude, did not give the authorities, upon which it is founded; an indispensable accompaniment, to any document upon which reliance is to be placed, and a loss to those who wish to study the matter beyond the bare enumeration of names.

I am, Sir, very faithfully yours,

April, 1840. Thos. L. Donaldson.

Sir—In your number of April, you have favoured your readers with a list of the Architects who have died in the 18th and 19th centuries, in which you have omitted the name of Charles Beazley, who died January 6th, 1829. He was a pupil of Sir Robert Taylor, and consequently the fellow student of Nash, Craig, Pilkington, Byfield, and Cockerill (the last of whom, as well as Craig and Byfield, are likewise omitted). Mr. Charles Beazley was the architect of the Goldsmiths' company, and a district surveyor nearly 50 years ago. He built a great number of gentlemen's seats, besides many buildings in London and its vicinity, and was likewise the architect of Faversham Church in Kent, which has been so generally admired.

Feeling that it is perhaps impossible for your collector to know the names of all the deceased architects, I trust that you will attribute this letter to the sole motive by which it is dictated, namely, to add such information as may enable you to correct your list should you republish it.

I remain, Your most obedient Servant,

29, *Soho Square, April* 3, 1840. SAMUEL BEAZLEY.

We have received another communication from Mr. Webb, for which we are obliged, containing the names of some architects, which were omitted in the table; we shall, at some future opportunity, avail ourselves of this communication, together with others, and publish an additional table. Editor C. E. and A. Journal.

TEACHERS OF CIVIL ENGINEERING, ARCHITECTURE, &c!!

SIR—As your highly useful journal is devoted to the advancement of the professions you advocate, allow me to draw your attention to what I consider to be an evil of the greatest magnitude, and one which has done more to lower the profession, and to bring it into disrepute, than anything else that I am acquainted with. I allude to the proceedings of a certain class of persons, styling themselves "Architects and Surveyors," or "Civil Engineers," who disgrace the profession they claim by pretending to teach it *in a few lessons*. Such men should be held up to universal scorn and contempt, for they have ruined the profession while filling their own pockets, by a process little better than swindling. I will explain the manner in which they go to work. They first put a specious advertisement in the newspaper, headed "Offices for Surveying, Architecture, and Civil Engineering," and go on to state that *a few lessons* are all that is required to enable a person to practise on his own account!! Some deluded individual is sure to be allured by this specious advertisement, for unfortunately, wherever there are dupes, there are sure to be knaves to take advantage of them.

Such persons, (the dupes,) find to their cost, that the business of an Architect, or Surveyor, or Civil Engineer, is not *quite so easily* acquired as they were at first induced to imagine by their *disinterested* instructor: instead of *a few lessons*, therefore, occupying a few weeks only, they are persuaded to go on with the farce for a few months, or until the master-hand thinks they will bear plucking no longer. He then lets them go, assuring them that they are *quite competent* to undertake *any survey whatever*, whether for canal, railway, or turnpike-road, and, if asked, furnishes them with testimonials to that effect, The newly fledged surveyor, or whatever he may choose to call himself, delighted with his newly and so easily acquired profession, hastens to put his skill to the test, and for this purpose, perhaps, takes an extensive parish to survey at a low rate, one, perhaps, that has to obtain the commissioners' seal, and for which he will therefore not be paid until it is completed to their satisfaction, and to that of Capt. Dawson, no easy person to please. He commences his work with confidence, but, after a short time becomes involved in a labryuth of perplexity and error, from which he cannot extricate himself; he, therefore, hastens back to his mentor to relate his misfortunes, and is persuaded by the latter to take a *few more lessons*, or perhaps is induced to employ him to survey the parish, for which he takes care to charge the "honorary" surveyor, about five times as much as he is himself to receive for the parish when completed. If endowed with a sufficient stock of gullibility and cash, the latter accedes, and after expending perhaps a much larger sum than he would have done, if he had placed himself with a respectable surveyor in a regular manner, he at length acquires a sufficient knowledge of the business to enable him to get on by himself without making many more blunders. In many cases, however, the aspirant is disheartened with his first failure, and declines the honour of being further taken in by his preceptor.

This is the way, Sir, in which the pockets of the unwary are picked, and the profession of the surveyor brought into disrepute; and the same remarks apply also to that of architecture, which our *professor* professes also to teach in a few lessons!!

Really, the barefaced impudence of some men exceeds all bounds, and yet we see the advertisements of these *highly respectable* members of the profession almost daily in the newspapers, a sure sign that they find it to answer their purpose, which is to fill their pockets at the expense of others.

I think, that you would be really conferring a benefit upon the profession generally, and on the rising generation in particular, by drawing attention to the tricks of these advertising quacks, who are in general, persons of no kind of reputation or ability, and who are therefore quite unqualified to give instructions in the business they profess. By pointing out also the fallacy and utter absurdity of a person endeavouring to acquire *in a few lessons*, a profession in which a man's *whole life* is barely sufficient to enable him to acquire all the minutiæ of his art, and in which there is always *something new* to be learnt, you may be the means of preventing the inexperienced from falling into such an error, and into the clutches of our advertising *professors*. The profession is already overstocked with persons regularly educated, and perfectly competent to practise it, but it is too bad that they should be continually brought into collision with, and made to suffer for the ignorance and blunders of others calling themselves "Architects and Surveyors," or "Civil Engineers," on the strength of a few lessons received from parties nearly as ignorant as themselves, and who are no more qualified to practice the professions they pretend to teach, than I am qualified to fulfil the duties of Lord High Chancellor.

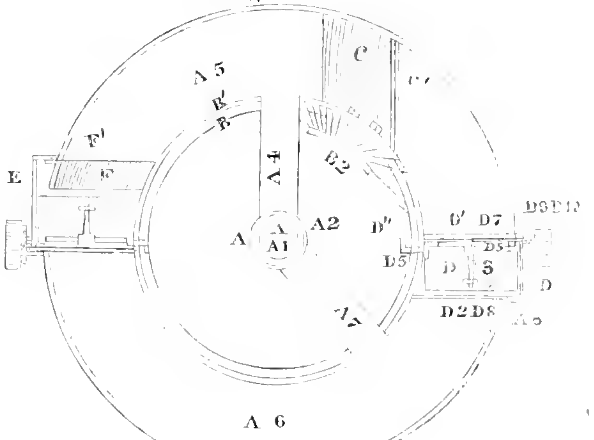
I have the honor to be, Sir,

London, April 17, 1840. ONE WHO HAS SUFFERED.

[We do not wonder that parties can be induced to think that civil engineering can be taught in a college, when there are those who believe that it can be required in a few lessons. What is to become of the hundreds of accomplished professors who are to be manufactured wholesale at the Gordon College?

MR. MOORE'S PATENT ROTARY ENGINE.

Fig. 1.



The following is a brief outline of this invention, taken from th specification.

A 5, A 6 is a hollow ring, or cylinder, with two pair of folding doors, D 3 and F, which open in the direction D, D 2, and F, F 1, and fall back into boxes to receive them. The doors of each pair open together by means of tooth wheels, and are closed again by coiled springs behind them, and afterwards pressed closely together by the elastic force of the steam, when the piston C has passed them. A, A 1 is a hollow axle, through one arm of which, at A, the steam enters, and passing through the tube A 4, just behind the piston, fills the space left between the piston C, and the folding doors F, next behind it. By its pressure on C, and confinement against the said folding doors, the piston (which is firmly connected with all the interior part A, A 2, &c.) and the said interior part revolve together in the fixed ring cylinder, A 5, A 6, in the direction C C'. As the piston C approaches the doors D 3, the beveled part B 2, acting on the ketch D 5, gradually opens the folding doors, which, after the piston has passed, close again by means of the coiled springs, and are kept tight by the steam issuing through A 4. Through A 7, A I, all the steam or air in advance of the piston passes off, and leaves the front side of the piston with no more than the common pressure of the atmosphere, as in all other engines, to oppose the piston.

This is the principle of the machine, and of its action, but a variety of contrivances are introduced—shown by other diagrams we have not thought it needful to insert—for the purpose of meeting and overcoming any difficulties in the way, and of rendering the machine more perfect.—*Railway Magazine.*

Electro-Galvanism.—At a lecture delivered at the Boston Mechanics' Institute, on Friday the 13th ult., by Mr. H. R. Gilson, the curator, he exhibited a most ingenious and important application of electro-magnetism to practical purposes, by which he is enabled to take the casts requisite for sterotyping in copper. They are at present made in plaster of Paris, and are seldom absolutely perfect; but by this novel application of science to the arts, stereotype plates may be produced as perfect and sharp as the type from which they are taken.

GENERAL THEORY OF THE STEAM ENGINE.

By Aristides A. Mornay, Esq.

No. VI.

On the Action of the Steam in the Cylinder of a Steam Engine,

(Continued.)

We shall first consider the most simple case, namely, that of a low pressure condensing engine without expansion, and with the ordinary slide valve, as the action of this valve is more simple than any other for calculation.

On the subject of the slides we have to observe, that, although their motion is gradual and as slow as it can be, yet there is no loss of effect arising from this circumstance. We should not have thought it necessary to mention this fact here, as we stated it cursorily in our last paper, but we have since seen a paragraph in Tredgold's Treatise on the Steam Engine, where he asserts the contrary. This paragraph is at page 204, and runs thus:

"When valves, cocks, or sliders are to be moved to admit steam to a steam-engine, the motion should be as quick as circumstances will permit, so that the passages may be wholly opened or wholly closed at the proper time with the least delay: for it may be easily shown that a considerable loss of effect arises from valves opening or shutting with a slow motion."

Now the slide, when it has no travel, takes one half of the duration of the stroke to open, and the other half to shut the ports; and, as the eccentric is placed a quarter of a revolution in advance of the crank, the ports are full open when the piston is at the middle of the stroke, and completely closed at each end. If, however, we can show that the aperture of the steam port is always proportional to the velocity of the piston, it will be proved that the steam will follow the piston with the same pressure from the beginning to the end of the stroke. This will, however, only apply to the steam port as regards the disadvantage of the slow motion of the slide; for the more rapidly the waste steam can be made to pass into the condenser, the greater effect will obviously be obtained from the steam.* At the beginning of the stroke of the piston, then, the slide is in the middle of its stroke; the piston has no velocity, and the steam-port is completely shut, but just ready to open, and its aperture increases in the ratio of the distance travelled by the slide from its present position in the middle of its stroke. Now that distance is equal to $e \sin a$, when the shaft has described the angle a, e being the eccentricity or distance of the centre of the eccentric from that of the shaft. In the same time the piston will have acquired the velocity $v \sin a$, if v is its velocity in the middle of the stroke. These two quantities evidently increase always in the same ratio, therefore the orifice of the steam-port is always sufficiently large to admit steam of the same elasticity as at the middle of the stroke of the piston, supposing no waste space to require filling with steam at the beginning of each stroke, and this is effected before the piston has described a sensible portion of its stroke, the steam having a much greater tendency to flow into nearly a vacuum than into steam of very little less than its own pressure.

In order to allow for the filling of the waste space with steam, we will suppose the slide, instead of having no lead, to have just so much as will allow that space to be filled with steam of the same elasticity as that in the steam-pipe, by the time the steam has arrived at the end of the cylinder, and is ready to begin its stroke, the aperture of the port being at the same time enlarged so much, that in the middle of the stroke of the piston it should be sufficient to allow the steam to follow the piston with the required elasticity. But, since this necessary lead of the slide and enlargement of the port are, as will be hereafter proved, excessively small, we shall omit to take them into consideration, merely assuming the effect for the sake of which these alterations were supposed, namely, that the waste space is already filled with steam of the same elastic force as that in the steam-pipe at the moment the piston commences its stroke.

Suppose now the piston in the middle of the stroke, in which case the steam port will be full open, and let the elastic force of the steam in the steam passages = P, that of the steam in the cylinder = p, the ratio of the area of the piston to that of the steam port = m, and V = the mean velocity of the piston in feet per minute. Let it be required to determine p when all the other quantities are known.

In order to solve this problem, we have to find, *first*, the velocity of the steam through the port necessary to enable it, when expanded to the elastic force p, which it assumes in the cylinder, to follow the piston with the velocity $\frac{\pi V}{2}$ which the piston has attained in the middle of the stroke; *secondly*, the height of a column of steam of the elasticity P, which would give it that velocity, and *lastly*, the pressure of that column, which will be equal to the loss of pressure which the steam suffers in entering the cylinder.

In the first place, the velocity of the steam through the port, if it retained its density, would be $\frac{m \pi V}{2}$; but, since we suppose a loss of pressure, we must also assume a diminution of density; and, if we call v' and v, the relative volume of the steam in the steam passages and in the cylinder respectively, the velocity through the port will be $\frac{v' m \pi V}{2 v}$. The height due to this velocity is,

$$h = \frac{v'^2 m^2 \pi^2 V^2}{28,800 g v^2},$$

and this is the height of the column of which the pressure is to be determined. This would evidently be known if we knew the height of the column whose weight is equivalent to the total elastic force P, which we shall therefore now endeavour to ascertain.

Let p and v be the elastic force and relative volume of steam at the temperature t, and p' and v' those of steam at the temperature t'; also let H be the height of a column of the former, whose weight is equivalent to its pressure p, and H' the height of a column of the latter whose weight is equivalent to its pressure p'. It is evident that we must have

$$\frac{H'}{H} = \frac{P' v'}{P v}.$$

But we have also

$$\frac{P'}{P} = \frac{v (t' + 448)}{v' (t + 448)} = \frac{v T'}{v' T'}$$

which value being substituted in the preceding equation, it becomes

$$\frac{H'}{H} = \frac{T'}{T}.$$

When $t = 212$, H is the height of the column of atmospheric steam equivalent to its elastic force, and H' that of the column of steam at any other temperature t' equivalent to its elastic force p'. Assuming the density of water to be 1700 times that of atmospheric steam, and the pressure of the atmosphere to be equal to the weight of a column of water 34 feet high, the value of H will be 57800 feet, and we shall have

$$H' = \frac{57800}{660} T',$$

or, reducing the coefficient and dropping the accents,

$$H = 87{\cdot}57576\ T.$$

Since the value of P is supposed to be known, we can find that of T by referring to a table, so that we may consider H as already determined, and therefore make use of it in the determination of the loss of pressure P — p, which the steam suffers in entering the cylinder.

As the two columns H and h have the same density, their pressures are evidently proportional to their altitudes, therefore

$$\frac{P - p}{P} = \frac{h}{H},$$

whence

$$P - p = \frac{v'^2 m^2 \pi^2 V^2 P}{28800 g v^2 H},$$

or, substituting for the constants π^2 and g their values, and for H its value 87·57576 T, as found above,

$$P - p = {\cdot}00000012156 \frac{v'^2 m^2 V^2}{v^2 T} P. \qquad (a)$$

We may be allowed to presume that the difference between v' and v in all cases which occur in practice is so trifling that the ratio $\frac{v'^2}{v^2}$ may, without any sensible error, be regarded as equal to unity, which will reduce the preceding equation to the following simpler one,

$$P - p = {\cdot}00000012156 \frac{m^2 V^2}{T} P. \qquad (b.)$$

* In condensing engines, working with low pressure steam, the resistance of the waste steam is usually considered as equal to the pressure in the condenser; we shall show in a future paper that where the slide valve is used with no lead, the pressure of the waste steam on the piston is much greater than in the condenser during a considerable portion of the stroke.

To show numerically by how much the pressure p of the steam in the cylinder may fall short of P, which is its pressure in the steam passages, we shall apply these formulæ to one or two examples, when we shall also show that the error introduced by neglecting the difference between v and v does not amount to so much as one hundredth part of a pound, whether the steam be used at a high or low pressure, provided the area of the steam passages be not excessively small, nor the velocity of the piston very great.

As a first example let $P = 14{\cdot}71$, $m = 25$, and $V = 240$. The temperature of the steam in the passages is in this case 212 degrees, which gives $T = 660$, and $v' = 1700$.

Having substituted these values, we find

$$P - p = {\cdot}00663\ P = {\cdot}0975 \text{ lb.},$$

whence

$$p = {\cdot}99337\ P = 14{\cdot}6125 \text{ lbs.}$$

The relative volume of steam of this elastic force is 1711, which makes $\frac{v''}{v'} = {\cdot}9872$, and if we multiply the above value of $P - p$ by this fraction, we shall obtain

$$P - p = {\cdot}0963 \text{ lb.},$$

which gives

$$p = 14{\cdot}6137 \text{ lbs.},$$

which differs from the former value by no more than ·0012 lbs., which is a negligeable quantity.

As an example of excessively high pressure steam, let $P = 130{\cdot}93$, and m and V the same as in the former example. In this case we have $T = 798$ and $v' = 2309$.

From formula (b) we obtain

$$P - p = {\cdot}005484\ P = {\cdot}718 \text{ lb.}$$

whence

$$p = 130{\cdot}212 \text{ lbs.}$$

The relative volume of steam of this elastic force is 2321, so that $\frac{v''}{v'} = {\cdot}9897$, and, multiplying by this fraction the value of $- p$ just obtained, the latter becomes

$$P - p = {\cdot}711 \text{ lbs.},$$

wherce

$$p = 130{\cdot}219 \text{ lbs.}$$

The error introduced by neglecting the fraction $\frac{v''}{v'}$ is therefore also in this case too small to be worth taking account of, so that we may always content ourselves with formula (b), when we wish to ascertain the loss of pressure which the steam suffers in passing through the steam port into the cylinder of a steam engine.

On referring to equation (b), it will be seen that the loss of pressure which the steam suffers in passing through the port into the cylinder varies *directly* as the square of the velocity of the piston, and as the square of the ratio of the area of the piston to that of the steam port, and *inversely* as the number of degrees by which the temperature of the steam in the steam passages exceeds — 148 degrees Fahr., which shows that, the higher the pressure of the steam used, the less is the comparative loss in passing through the port, and, the greater the velocity of the piston, the larger the steam port must be in the same proportion, that the loss of pressure may be the same.

We assumed a rather considerable value for V in the above calculations, in order to show more satisfactorily how trifling is the error which can be committed in deducing the elastic force of the steam in the cylinder from that in the steam passages. By making $V = 210$ feet per minute, which is the speed usually given to the piston of an engine, instead of 240, which we assumed above, the value of $P - p$ will be reduced in the ratio of 210^2 to 240^2, or 49 to 64. When therefore the area of the steam port is one 25th part of that of the piston, and the mean velocity of the piston is about 210 feet per minute, we may assume, as an average for low pressure engines,

$$P - p = {\cdot}005\ P,$$

or

$$p = {\cdot}995\ P;$$

and for high pressure engines,

$$P - p = {\cdot}0046\ P,$$

or

$$p = {\cdot}9954\ P.$$

It is a very good plan to fix a steam guage on to the slide box, or steam pipe very near the cylinder, as that dispenses with the calculation of the loss of elastic force experienced by the steam during its passage through the steam pipe, before it arrives at the slide box.

When speaking of the lead of the slide necessary to allow the waste space at the end of the cylinder to be filled with steam before the beginning of the stroke of the piston, we said we should prove it to be excessively small. The calculation of the exact lead required for that purpose is very long and difficult, involving integrals of a very complicated nature; but it will answer our purpose equally well to prove it for a greater lead than necessary, for it will then be proved à fortiori for the necessary lead.

Let P be the elastic force and D the density of the steam in the steam pipe, and let H = the height of a column of the same steam whose weight is equivalent to its pressure. Also let p be the elastic force, and δ the density of the steam in the waste space when the port is open to a certain degree, a the area of the orifice at that moment, v the velocity of the steam through it, and q the volume of steam of the density D which has passed through the port, and let d be the density of the steam in the condenser, and consequently also in the waste space before the port has begun to open. In the case of non-condensing engines d is equal to the density of atmospheric steam, or 1. Also let c be the contents of the waste space, A the area of the piston, L the length of the stroke, and $\frac{1}{n}$ the ratio of the area of the steam port to that of the piston.

The height of the column of steam equivalent to the pressure $P - p$, to which the flowing of the steam through the port is due, is equal to $H\left(1 - \frac{p}{P}\right)$, the velocity will therefore be equal to

$$v = \sqrt{2\,g\,H\left(1 - \frac{p}{P}\right)}.$$

But this formula would lead to very complicated calculations, as we have already observed, for which reason we shall substitute the fraction $\frac{\delta}{D}$ for $\frac{p}{P}$, which will render the case less favourable; for the former being greater than the latter, the factor $\left(1 - \frac{\delta}{D}\right)$ is less than $\left(1 - \frac{p}{P}\right)$; wherefore also the value of v will be less after the substitution than before, and consequently the time required to raise the pressure of the steam in the waste space to the maximum which it attains in the cylinder will appear greater than it really is. If therefore we can prove this to be exceedingly short, it will be demonstrated à fortiori for the true time. We shall therefore assume, in place of the above equation

$$v = \sqrt{2\,g\,H}\,\sqrt{1 - \frac{\delta}{D}},$$

or

$$v = \sqrt{\frac{2\,g\,H}{D}}\,\sqrt{D - \delta}. \qquad (1.)$$

We have also between the variable quantities q and δ the following relation

$$c\,\delta = q\,D;$$

whence

$$q = \frac{c}{D}\,\delta,$$

And, by differentiation,

$$\text{dif. } q = \frac{c}{D}\,\text{dif. } \delta.$$

But we have also

$$\text{dif. } q = a\,v\,\text{dif. } t,$$

where dif. t is the infinitely small space of time during which the infinitely small quantity of steam dif. q of the density D passes through the orifice a. These two equations, having their first members equal, give

$$\frac{c}{D}\,\text{dif. } \delta = a\,v\,\text{dif. } t. \qquad (2.)$$

Let $b\,r$ represent the area of the steam port when full open, b being its constant length and r the greatest width to which it is opened by the eccentric, which is equal to the eccentricity of the latter; we shall then have, calling θ the angle described by the eccentric from the moment when the port began to open till its aperture had become equal to a,

$$a = b\,r \sin \theta: \qquad (3.)$$

whence we obtain by differentiation

$$\text{dif. } \alpha = b\,r \cos \theta \text{ dif. } \theta,$$

or

$$\text{dif. } \theta = \frac{\text{dif. } \alpha}{b\,r \cos \theta}.$$

But equation (3) gives

$$b\,r \cos \theta = \sqrt{b^2\,r^2 - \alpha^2},$$

which, being substituted, makes

$$\text{dif. } \theta = \frac{\text{dif. } \alpha}{\sqrt{b^2\,r^2 - \alpha^2}}.$$

And, if we call τ the duration of a single stroke of the piston, or half a revolution of the shaft, we shall also have

$$t = \frac{\theta}{\pi}\,\tau;$$

whence by differentiation

$$\text{dif. } t = \frac{\tau}{\pi} \text{ dif. } \theta,$$

which becomes by substituting the value of dif. θ just found

$$\text{dif. } t = \frac{\tau}{\pi\,(b^2\,r^2 - \alpha^2)^{\frac{1}{2}}} \text{ dif. } \alpha.$$

Substituting this value, as well as that of r given by equation (1), in equation (2), this latter becomes

$$\frac{\text{dif. } \delta}{(\mathrm{D} - \delta)^{\frac{1}{2}}} = \frac{\tau\sqrt{2\,g\,\mathrm{H\,D}}}{c\,\pi}\;\frac{\alpha \text{ dif. } \alpha}{(b^2\,r^2 - \alpha^2)^{\frac{1}{2}}}. \qquad (4).$$

The greatest value which δ can acquire, being equal to the maximum density of the steam in the cylinder during the stroke of the piston, cannot be quite equal to D, but will not fall far short of it. On the other hand it is evident that, if we assume D as the maximum value of δ, the hypothesis will be unfavourable to our demonstration; we are therefore permitted to make it; and as the minimum value of δ is equal to d, we must integrate the first member of preceding equation between the limits $\delta = \mathrm{D}$ and $\delta = d$. The limits of the value of α in the second number are $\alpha = a$, the aperture of the port when δ has attianed its greatest value, and $\alpha = o$. We must therefore have

$$\int_d^{\mathrm{D}} \frac{\text{dif. } \delta}{(\mathrm{D} - \delta)^{\frac{1}{2}}} = \frac{\tau\sqrt{2g\,\mathrm{H\,D}}}{c\,\pi}\int_o^a \frac{\alpha \text{ dif. } \alpha}{(b^2\,r^2 - \alpha^2)^{\frac{1}{2}}}. \qquad (5.)$$

In the first integral let $\mathrm{D} - \delta = x$; then dif. $\delta = -$ dif. x, and

$$\int_d^{\mathrm{D}} \frac{\text{dif. } \delta}{(\mathrm{D} - \delta)^{\frac{1}{2}}} = -\int_o^{\mathrm{D}-d} x^{-\frac{1}{2}} \text{ dif. } x.$$

$$= -2\,(\mathrm{D} - d)^{\frac{1}{2}}.$$

In the second integral make

$$b^2\,r^2 - \alpha^2 = z.$$

By differentiation we obtain

$$\alpha \text{ dif. } \alpha = -\tfrac{1}{2} \text{ dif. } z.$$

We have, therefore,

$$\int_o^a \frac{\alpha \text{ dif. } \alpha}{(b^2\,r^2 - \alpha^2)^{\frac{1}{2}}} = -\int_{b^2\,r^2 - a^2}^{b^2\,r^2} \frac{1}{2}\,z^{-\frac{1}{2}} \text{ dif. } z.$$

$$= -\left[b\,r - (b^2\,r^2 - a^2)^{\frac{1}{2}}\right].$$

Substituting these values of the integrals in equation (5), we obtain

$$2\,(\mathrm{D} - d)^{\frac{1}{2}} = \frac{\tau\sqrt{2\,g\,\mathrm{H\,D}}}{c\,\tau}\left[b\,r - (b^2\,r^2 - a^2)^{\frac{1}{2}}\right],$$

and, substituting for a its value given by equation (3),

$$2\,(\mathrm{D} - d)^{\frac{1}{2}} = \frac{\tau\sqrt{2g\,\mathrm{H\,D}}}{c\,\pi}\left[b\,r - b\,r\,(1 - \sin.^2\,\theta)^{\frac{1}{2}}\right]$$

$$= \frac{b\,r\,\tau\sqrt{2\,g\,\mathrm{H\,D}}}{c\,\pi} \text{ sinv. } \theta;$$

whence we deduce

$$\text{sinv. } \theta = \frac{2\,c\,\pi\sqrt{\mathrm{D} - d}}{b\,r\,\tau\sqrt{2\,g\,\mathrm{H\,D}}};$$

or, putting for $b\,r$, which is the area of the steam port when full open, its value $\frac{\mathrm{A}}{n}$,

$$\text{sinv. } \theta = \frac{2\,n\,c\,\pi\sqrt{\mathrm{D} - d}}{\tau\,\mathrm{A}\sqrt{2\,g\,\mathrm{H\,D}}}.$$

Now $\frac{\mathrm{L} \text{ sinv. } \theta}{2}$ expresses the distance passed through by the piston while the shaft describes the angle θ round its axis, and consequently during the time the waste space is filling with steam, therefore, if we call l that distance, and $\frac{1}{\mathrm{S}}$ the ratio of the waste space c to the contents of the cylinder between the limits of the stroke, we shall have $c = \frac{\mathrm{A\,L}}{\mathrm{S}}$, and

$$l = \frac{n\,\pi\,\mathrm{L}^2\sqrt{\mathrm{D} - d}}{\mathrm{S}\,\tau\sqrt{2\,g\,\mathrm{H\,D}}},$$

or

$$\frac{l}{\mathrm{L}} = \frac{n\,\pi\,\mathrm{L}\sqrt{\mathrm{D} - d}}{\mathrm{S}\,\tau\sqrt{2\,g\,\mathrm{H\,D}}} = \frac{n\,\pi\,\mathrm{L}\sqrt{1 - \frac{d}{\mathrm{D}}}}{\mathrm{S}\,\tau\sqrt{2\,g\,\mathrm{H}}}$$

or, since the densities are inversely as their relative volumes,

$$\frac{l}{\mathrm{L}} = \frac{n\,\pi\,\mathrm{L}\sqrt{1 - \frac{\mathrm{V}}{v}}}{\mathrm{S}\,\tau\sqrt{2\,g\,\mathrm{H}}} \qquad (6.)$$

As an example for low pressure steam, let $\mathrm{L} = 5$, $n = 25$, $s = 20$, $\mathrm{P} = 17{\cdot}78$ lbs., whence $\mathrm{V} = 1427$, $\mathrm{T} = 670$ and $\mathrm{H} = 58675{\cdot}7576$; let the temperature of the condenser be 110 degrees, in which case $v = 14952$; and, if we suppose the piston to move through 200 feet in a minute, $\tau = 1{\cdot}5$ second. We have besides $\pi = 3{\cdot}1416$ and $g = 32{\cdot}19$.

Substituting these values in the second member of equation (6), we obtain

$$\frac{l}{\mathrm{L}} = \frac{3{\cdot}1416 \times 25 \times 5\sqrt{1 - \frac{1427}{14952}}}{1{\cdot}5 \times 20\sqrt{64{\cdot}38 \times 58675{\cdot}7576}} = {\cdot}0032.$$

In the example chosen the value of l would thus be less than one-fifth of an inch, and it will be remembered that this value is too great in consequence of our having substituted the ratio $\frac{\delta}{\mathrm{D}}$ for $\frac{p}{\mathrm{P}}$.

As an example for high pressure steam, we will take the data from locomotive engines, and assume $\mathrm{L} = 1{\cdot}5$, $n = 15$, $s = 20$, $\mathrm{P} = 77{\cdot}95$; whence $\mathrm{V} = 359{\cdot}5$, $\mathrm{T} = 760$, and $\mathrm{H} = 66557{\cdot}576$; also $v = 1700$; and, if we suppose the piston to move through 360 feet in a minute, $\tau = {\cdot}25$ second.

Substituting these values, we find

$$\frac{l}{\mathrm{L}} = \frac{3{\cdot}1416 \times 25 \times 1{\cdot}5\sqrt{1 - \frac{359{\cdot}5}{1700}}}{{\cdot}25 \times 20\sqrt{64{\cdot}38 \times 66557{\cdot}576}} = {\cdot}0107.$$

In this example, therefore, the value of l is but a trifle more than ·18 of an inch, or less than $\frac{3}{4}$ of the lead of $\frac{1}{4}$ of an inch usually allowed in locomotives.

The ratio $\frac{l}{\mathrm{L}}$ also expresses the proportion of the whole area of the steam port by which its aperture is diminished at the moment the piston reaches the middle of its stroke, and as this quantity is, as the two above examples show, exceedingly small, it is unnecessary to make any allowance for it.

A FEW REMARKS ON THE CONSTRUCTION OF OBLIQUE ARCHES, AND ON SOME RECENT WORKS ON THAT SUBJECT.

Until within the last few years, the construction of oblique bridges has been but little understood, from a doubt as to their stability, and from the difficulty of their construction, they were regarded to a certain degree with distrust, and the engineer would only have recourse to them when the circumstances of the case were imperative: the superior scientific acquirements of the engineers of the present day, however, the assistance of various books on the subject, and the great experience obtained in this species of construction, by the demand occasioned for them in the large railway undertakings which have lately occupied so much of the public attention, have contributed materially to remove the veil of mystery which formerly hung over them: the doubt which was at one time entertained of their stability is removed, the oblique bridge is now generally adopted, and the only point remaining to be cleared up is, as to the best method of working the parts together, so as to obtain the desideratum of engineering, viz., stability, economy, and beauty of appearance.

Since the commencement of the London and Birmingham Railway, four authors have written on the construction of oblique bridges, Mr. Fox, Mr. Hart, Mr. Buck, and Mr. Nicholson. It should be observed, with reference to the two latter, that Mr. Buck's work appeared before the third part of Mr. Nicholson's was published. The announcement of a work on this subject, by a person whose reputation as an author, stood so high as that of Peter Nicholson, naturally gave rise, in the practical world, to the hope that the difficulties which had heretofore attended the constructing of oblique bridges would, with his powerful assistance, be much reduced, if not entirely removed, but that our most reasonable anticipations are sometimes doomed to disappointment, was never more signally shown than in this instance. A few quotations will be sufficient to give a specimen of the errors and inconsistencies which, we regret to say, characterize this book. Mr. Nicholson says in his preface, "In this undertaking, the general reader is not supposed to be much acquainted with scientific researches," and he accordingly goes on, in the introduction, to inform him that a right angle contains ninety degrees, that 60 minutes make a degree, and that "a number having a small zero or cypher placed over the right hand shoulder of the figure or last figure, shows this number to be as many degrees as the figure or figures express." At page xx of the introduction, he says, "If a spiral surface be cut by a plane obliquely to the axis of the cylinder, the section will be a curve of contrary flexure, and if the spiral surface be cut by another plane passing along the axis, perpendicular to the first plane, the section, which is a straight line, will intersect the curve of contrary flexure at the point of retrogression." The first of these paragraphs appears intended for a person who has only learnt to read and write, while the second, it must be admitted, seems little adapted to the understanding of those who are unacquainted with scientific researches.

In Section IV, page xxiii, which treats of the trihedral, he states that "If a trihedral be cut by a plane perpendicular to one of its oblique edges, the section shall be a right angle." Now a trihedral may have all three of its edges oblique, or one obtuse and two oblique edges, or one right and two oblique edges, and the above assertion only holds good with regard to the latter; with such a glaring error as this among the definitions on which his trihedral system is founded, it is of course unnecessary to examine it further. One part of the subject in which Mr. Nicholson has been very unfortunate, is relative to the sections of spiral surfaces; of this we will only give one instance here, as we shall have occasion to return to this subject. He says, page 24, "the transverse section is, therefore, the only section of the spiral surface which is a straight line." Whereas, in introduction, page xix, we find, "If a spiral surface be cut by a plane, either perpendicular to or passing along the axis, the section will be a straight line."

The history and theory of oblique bridges is, by some system of arrangement peculiar to the author, placed after the problem for constructing the templets for working arch stones, and is followed by a practical method for obtaining the templets. This history, so curiously placed, appears to be introduced chiefly for the opportunity thereby afforded the author of making his own strictures on other works; but in his anxiety to detract from the merits of all authors but himself on this subject, he has again fallen into so many errors, as to leave no doubt of his being but superficially acquainted with the subject on which he writes.

Mr. Fox has asserted, in common with other writers on the oblique arch, that, "when the soffit is developed, the edge which formed the face of the arch gives a true spiral curve." Upon this Mr. N. remarks, "It must, however, be observed, that the edge of the developed semi-ellipse is neither a spiral line nor the projection of a spiral line." In this remark Mr. Nicholson is decidedly wrong, for it is easy to demonstrate that the curve above mentioned is the projection of a true spiral, whose radius is equal to half the obliquity of the arch, and whose length is equal to the semicircumference of the cylinder on which the arch is assumed to be built. With reference to Mr. Fox having stated that the joints in the face are curves, Mr. N. says, "if they had been curves, the curvature would have been so small, that the joint lines would not have varied sensibly from straight lines. The true curvature of the joint could not, therefore, have been expressed in lines," Now if Mr. Nicholson had ever had occasion to put his rules into practice in a bridge of considerable obliquity, he would have found that the face joints near the springing are not only curves, but very perceptible ones. There is, moreover, nothing impossible in constructing the curves formed by the face joints, it is nearly as simple as the construction of the spiral itself; but this is a part of the subject on which Mr. Nicholson is throughout unfortunate.

Mr. Buck's Essay on the Oblique Bridge next falls under our author's scrutiny: that it should receive his entire disapproval, is not perhaps surprising. Mr. Buck has had the advantage of Mr. Nicholson in being able, while engaged on the London and Birmingham and other railways, to put his rules into practice, and prove them to be right before he laid them before the public; he has, for the same reason, been able to select the useful parts, and present them to the reader unencumbered by the superfluous and weary waste of words through which Mr. Nicholson's readers are doomed to wander. Relative to this work Mr. Nicholson proceeds to say, "The formula $co = (r + e)$ $\cot\theta \tan B$ is due to Mr. Buck; it gives the distance below the centre to the point of convergence, into which all the joints in the elevation of the arch meet in the axis minor, supposing that the joints are straight lines, which they are not exactly." This having reference to the section of the spiral surface, no wonder Mr. Nicholson is again unfortunate. Mr. Buck does not wish his readers to turn the curves into straight lines, which peculiar operation, if properly conducted, is to cause the straight lines to converge to a point. He simply gives the point to which the chords of the said curves so converge, and the formula for finding this point is not all that is due to Mr. Buck, but the discovery of the fact that they do converge to a point, and the uses to which this discovery can be applied in facilitating the construction of the bridge.

Mr. Nicholson next complains that Mr. Buck has given, besides his general formula for finding the point of convergence, another formula which happens to be more convenient when making the necessary calculations for the segmental arch. He concludes at once that the results of these formulæ must differ, and puts forth his assertion to the world as if the book were in error. His concluding paragraph relative to Mr. Buck's book is, "One thing which we consider defective in Buck's Essay on Oblique Arches is, that his intentions are not enunciated under regular heads, so as to call the attention of the reader; he gives no reason for his rules, nor does he show the principles upon which his formulæ depend. The height of the point o, Fig 7, will depend upon the breadth of the beds."

The first part of this remark we will leave Mr. Nicholson to settle with his conscience in the best way he can. As regards the second part, we would ask what is the E in Mr. Buck's formula if it is not the breadth of the beds or the thickness of the arch, which is one and the same thing? Mr. Nicholson ought, in justice, to ascertain that an error really exists, before he implies that such is the case. That he has not long been acquainted with the fact of the chords of the joints in the face converging to a point below the axis of the cylinder, is evident from his book on stone cutting, in which the joints are drawn at right angles to the curve, and that he was unaware of the utility of knowing this point is equally evident, or he would never have given the laborious and complicated construction for finding the joints in the face, beginning at page 17.

Mr. Nicholson gives rules for what he terms two kinds of oblique bridges, namely, those in which the joints of the stones are planes, and those in which they are spiral surfaces; these rules are so jumbled up together, that the reader is at a loss to know to which of the two species of bridges they refer. At page 15 there is a problem, "To find the curved bevels for cutting the quoin heads of an oblique arch." The reader being unable to learn from the heading of the problem whether it relates to square or spiral joints, naturally proceeds to wade through it, with the hope that it may afford some means of ascertaining this fact, but here he soon becomes lost in a labyrinth. You are told to divide the arc A B C into as many equal parts as the ring stones are in number, and through the points of division draw $b\,k$, $c\,i$, $d\,j$, &c., perpendicular, to the curve A D E. A B C and A D E being two different curves in two different directions, there is evidently a great omission somewhere, which, however, we might forgive if his meaning could be discovered, but it cannot. A little further on he tells you to join *a m*, *b m*, *c m*, &c., but where the point *m* is to be placed, Mr. Nicholson has quite forgotten to say.

Page 10, referring, as is stated at the head of the page, to plate 21, is another example in which, from the type being completely at variance with the plate, we are left quite in the dark as to what the author wishes to communicate.

The practical part of this work, if, indeed, any part may be so called, is scarcely less defective than that of which we have already spoken; the direction for dividing the face of the arch into stones of unequal thickness is unworkmanlike and unsightly, and where brick-work is used, the joints must necessarily be larger on one side than on the other.

On the whole it must be admitted that the book is far from being worthy of the great reputation Mr. Nicholson has hitherto justly acquired; it has the appearance of being got up by his journeymen, and signed with his name without a sufficiently careful revision. But we have said enough, though, in closing the book, we cannot but express a wish that, before he had sought the mote in his brother's eye, he had removed the beam from his own.

Manchester, W. H. B.
March 26, 1840.

MARINE ENGINES.

Employment of the expansive principle to its full extent in Marine Engines, with a saving of half the fuel.

Sir—In my remarks in your Journal of last month I dwelt at some length on the advantages to be derived from the employment of the Cornish double beat valve in marine engines, especially the facility which such afford of working the steam expansively. But it may be asked why all this talk of working expansively where there is little or nothing to expand? I would answer this question by another: why adopt a good plan by halves? take the Cornish boilers also, or a suitable modification of them, and raising the steam to 35 lbs. effective, carry out the principle of expansion to its full extent; this would at once reduce the consumption of coal one half, and so double the range of our steam navigation. On such a startling proposition as this being mooted, the question naturally suggests itself, how has this so long escaped the first men of the day? That I shall not attempt to answer; it is sufficient that it has escaped them, and a very slight examination of the matter will make this evident.

Thus taking the horse power at 33,000 lbs. lifted one foot per minute with a consumption of 8 lb. of coal per hour, and this is below the average consumption, we get a duty of 23,000,000 (though 20,000,000 would be nearer the mark, especially in steam boats).

If any be disposed to assert that this is overstated as regards the Great Western and British Queen, as these vessels are said not to consume above six or seven pounds per horse power per hour, I answer, the Queen's engines are 500 horse power at 15 strokes per minute, or the piston travelling through 220 feet per minute, now the pressure of steam, &c. remaining the same, the power exerted by the engine is exactly as the space through which the piston travels; but 12 strokes per minute is nearly the average number the engines make, as appears by her log; this reduces her power in the ratio of 15 to 12, and increasing the consumption of fuel per horse power in an equal ratio, makes the six or seven pounds nominally consumed equal to 8 or 9.

Whereas many of the Cornish double acting crank engines used for stamping ores, the most trying work an engine can possibly be subjected to, and where there is greatest loss by friction, are doing a *duty* of 50, 56, and even 60,000,000, as appears from the authenticated reports of the engineers.

Although this will not be doubted by any one who has had the opportunity of seeing the engines at work, it may suit some to doubt and even to deny the truth of these reports; so they did those of the pumping engines doing a 70 or 80,000,000 *duty*; but as 90, and even 100,000,000 is now being done under their eyes, what credence can such men expect for any statement they may in future make.

Having had occasion to visit Cornwall some three years ago on business, immediately after having completed the engines of a large vessel now on the London and Dublin station, the easy valves, the cool engine room, and almost smouldering fires of the Cornish engines, as contrasted with the stiff and heavy slides, the suffocating heat of the engine room, and roaring furnaces I had just left, attracted my particular attention; and though possessing at that time no data beyond the published reports of the engineers, I saw enough to convince me of their immense superiority, and at once set about considering how the same plan could be carried out in marine engines, a point which I hope to be now able to make clear, and the objections to which I shall endeavour to deal with in detail.

The first is the increased danger of explosion or collapse supposed to be occasioned by the great density of steam.

The second is the additional strength required in the engines to withstand steam of such density when first admitted into the cylinders.

The third is the increased weight of the boilers, and the extent of flue surface required for their successful application.

The first objection, the increased danger, I shall begin by denying "in toto," nay, it appears to me that there is absolutely increased safety, for the following reasons:

Setting aside the increased weight, &c., one boiler can be made quite as capable of supporting a pressure of 35 lbs. as another is of supporting 3 lbs.: the safety valves would have much less tendency to stick fast under the higher pressure, and their becoming a little stiff, or two or three pounds overloaded, would not be of the slightest consequence on a boiler calculated for a pressure of 35 lbs., though it would have a very dangerous tendency on one calculated for 3 lbs.

But the great argument for increased safety is this: it is an established fact that with boilers of the usual construction, nine-tenths of the steam boat accidents occurs through collapse of the overheated flues, much more than from any excessive pressure of steam in the boiler; nor is this to be wondered at if we consider how the fires are urged. Now with the Cornish boilers and a proper system of expansion, the same work can be done with half the coal, and if we consume only half the coal on the same or a greater extent of fire bar and flue surface in a given time, then it follows clearly that we have a fire of only one-half the intensity, and the risk of collapse from overheated flues diminished in like proportion. But if these arguments are insufficient, then the following fact is greatly in their favour, viz., that as few if not fewer accidents occur in Cornwall where such boilers are in universal use, than in any part of the kingdom where steam power to a like extent is used; and if it be further true, as I have heard stated both in Cornwall and elsewhere, that many of the Cornish engineers will engage to keep up the boilers for ever, for the annual sum of 5 or 6 per cent on their original cost,* such an argument appears to me, as it will to most practical men, to be at once perfect and conclusive.

I now come to the increased strength required in the engines, and this on examination will appear trifling. To commence then with the paddle-wheels as they remain of the same size, and are driven at the same speed, no alteration is required in them, and of course the same remark will apply to the paddle-shafts through which the power is transmitted. These being subjected to no increased strain as the average effective pressure upon the piston which takes place when the piston is half stroke, &c., and the crank at its point of greatest torsion, is the same as in a common engine. The intermediate shaft alone with its cranks, in which the crank pins are *fast*, requires additional strength, and as this shaft is only about one-sixth the length of the two paddle shafts, and the strength of a shaft increases as the cube of its diameter, the increased weight will be trifling: next there is the top frame that carries this shaft, and the bottom frame supporting the gudgeons and columns, the strength of both must be increased, and it is as the square of their depth; next comes the piston rod, this will do as before, the piston rod of a large engine being equal to 20 times the strain it is ever subjected to: the same remark will apply to the malleable iron columns supporting the top frame, as each of them is usually made of the same strength as the piston rod.

The piston must be strengthened, but the cylinder will do as before, as it is strengthened at the extremes where the greatest pressure of the steam is by its flanges, and in ordinary cases we are under the necessity of making it much stronger then necessary to ensure a sound casting, and also to support the framing attached to it; besides a cylinder of three-fourths the capacity is sufficient for the same power, so here we are positive gainers in two most important points, strength and space. The gudgeons of the cylinder of double the strength will not be stronger nor heavier than the main centres of the beam engine of the ordinary construction must necessarily be.

The points then which require increased strength are, the intermediate shaft and gudgeons, the top and bottom supporting frames, and the piston. The increased weight from this cause would not exceed 6 or 8 per cent. beyond that of the same description of engine at the ordinary pressure, and after taking this into account, the total decrease, by adopting the vibrating cylinder, would be at least 25 per cent.

I now come to the question of increased weight in the boilers, and

* Perhaps some of your readers can affirm or contradict this.

this I shall be able to show is not nearly so great as may at first be supposed.

It will scarcely be disputed that the same thickness of plate in cylinders 6 feet diameter, the size of the exterior cylinder of the Cornish boiler, will bear a water pressure at least 3 times greater than if arranged in the usual form of a steam boat boiler: or that the former of 5-16th thickness would bear without flinching a proof pressure of 60 or 70 lbs. to the square inch, while the latter would give evident signs of weakness at 20, although ever so well stayed. If then it be considered perfectly safe to work steam of 6 or 7 lbs. pressure in a boiler which would give evident signs of weakness under a pressure of 20 lbs., surely it is equally safe to work steam of 30 or 35 lbs. in a cylinder of 6 feet diameter, and ½ inch thick, which would bear without the slightest signs of weakness 120 lbs. on the square inch, boilers of this size and thickness being usually worked to 40, 45, and even 50 lbs. per square inch Then 4 feet diameter, and 7-16ths thickness will be ample for the internal cylinder, and to make security doubly secure, let a strong angle iron be rivetted round the internal cylinder at distances of about 2 feet apart, this would keep the cylinder or arch perfect, and so prevent the possibility of a collapse, with but trifling addition to the weight of the boilers.

Now taking equal extent of common and Cornish boilers, the former taking all stays, &c. into account, will barely average 3-8ths in thickness, while the latter with its internal tube of 18 inch diameter, and 5-16ths thickness, would average about ½ inch. This makes their respective weights at 3 to 4, but in order to the successful application of slow combustion we require addition flue surface, so take 3 to 5 as the ratio of the weight of common and Cornish engines and water for the same power, the extra space required for the boilers being much more than compensated, by the small space occupied by the vibrating engine.

But to go more minutely into the matter, the weight of a Cornish boiler and water of the size and thickness named, and 35 feet in length, is = 24 tons, exposing a surface 938 feet: eight such boilers might be easily set in the space allowed for the Queen's boilers, now $8 \times 24 = 192$ tons, as the weight of the boilers, and allowing 50 tons for setting and clothing, we have $192 + 50 = 242$ tons, total weight of the boilers and setting, &c.; $938 \times 8 = 7504 \div 500 = 15$ feet surface per horse power, being one-half more than the usual allowance without increasing the weight of the boiler at all, or occupying more space in the vessel.

But allowing that we have increased the weight of the boilers in the ratio of 3·5, let us take the British Queen as the subject of comparison.

The total weight of her engines and boilers is 500 tons, and of this 220 may go in round numbers for boilers and water, and $3 : 5 :: 220 : 366$, and $500 - 220 + 366$ gives 664 and less 64 tons being the decreased weight of the vibrating engine = 600 tons, as the weight of her engines and water on the Cornish plan.

The account would then stand thus, on the present plan,

Engines and boilers - - - - - -	500 tons
20 days fuel - - - - - - -	750
Total - -	1250

On the Cornish plan,

Engines and boilers - - - - - -	600
20 days fuel - - - - - - -	375
Total - -	975

Showing a capacity for 285 tons more cargo, and a saving of 375 tons of coal.

Though some may consider these figures as exaggerated without being able to assign any reason to themselves or others, save that the plan is impossible. Those who have examined the subject will assuredly blame me for not having gone far enough; and there is another class of well meaning men among engineers and others, who have imbibed such a reverence for the name of Watt, that they almost consider any deviation from the plans he followed, or improvements upon the state in which he left the steam engine, to be an insult to his memory, and a deduction from his fair fame; but my admiration of Watt is as great as any man's can be; I am proud of him as a countryman, and honour him as a great man, and so have endeavoured to add a stone to the monument he has raised, by carrying out a principle which in his third patent of 1782, he distinctly propounded, and of the advantage of which that great man seems to have been fully aware, though he lived not to see it carried into effect.

If then I am born out in these statements, and to disprove the main point, the great increase of duty by expansive working is altogether impossible; and the others I think I have succeeded in making tolerably clear, though on some points as the weight of the present boilers and water of the British Queen, I may have made some slight mistake, not amounting to a few tons either way, having assumed it from comparison with others, and not stated it from actual knowledge, yet on the other hand I have underrated the saving of fuel, and allowed quite enough for the increased weight of the boilers, as there is less due to the great extent of surface than is supposed, the expansion being the point where the power is gained; and however the proposition of adopting steam of increased density may be cavilled at, to the principle of expansive working and slow combustion we must come at last, and by adopting them to their full extent, which I think I have shown to be equally safe and perfectly practical. The Cape of Good Hope is as much within our reach as New York now is, and a speedy and sure passage open to our Indian and Australian empires.

Such then being the case, are we content to allow our preconceived ideas to supersede our better judgment, and go on loading our vessels with unnecessary coal, and thus uselessly consuming our most valuable mineral—limit at the same time the range of our steam navigation, and the civilization of the world at large; or do our engineers mean to allow that they cannot make a boiler safe under a pressure of 35 lb., or that one of the thickness and diameter that I have proposed would not be perfectly safe under that pressure. If they allow neither of these propositions, then the sooner the subject is seriously taken up the better, as every boat now fitting with the usual beam or side lever engines, (and many of the splendid mail packets are being thus fitted), is incapable of being afterwards altered, so as to work expansively, as though the boilers may be altered, the beams, &c. would never stand the increased pressure.

Before concluding, perhaps I may be allowed to correct an omission in my last paper. It is a favourite remark of naval men, "get as extended a hold of the vessel as possible." Now it has often struck me, not only in those vessels I have myself been engaged in, but in every one I have had the opportunity of seeing, that this very reasonable remark is not only not complied with, but that the power is positively brought to bear on the wrong place. Thus no attempt that I have seen has been made to lay hold of the vessel fore and aft in a line with the centre of the paddle shaft, but the framing is stayed sideways, or at best slightly supported by the most contiguous deck beams, and the horizontal strain of the propelling power acting at the bearings of the shaft, the engine frame is thus used as a lever to wrench the under frame of the vessel as it were asunder, and an action is thus created tending materially to weaken the vessel and increase the unpleasant vibration, to remedy this defect, and at the same time to prevent the framing and joints of the engine from breaking, uncommonly heavy bed plates have been resorted to; those on board the British Queen amounting at least to 23 tons; now without entering into a discussion on the point, what I propose is this, let a strong flat bar of wrought iron be carried fore and aft opposite each engine, gradually tapering away, and running in towards either side of the vessel, being at the same time securely bolted through ten or twelve of the deck beams, on the end of this next the engine, let there be a strong joint and a similar one on the engine frame joined by a strong connecting rod, this would allow sufficient play, and at the same time, if I may use the expression, give the porter a hold of his load by the right place.

To conclude, if it be considered that I have not gone sufficiently into detail completely to prove every point I have advanced, my answer is, I have considerably underrated the gain, and overrated the loss, thus rendering minute calculation of strength and weight uncalled for; besides such would have been of no value to any one not intimately acquainted with the subject, and practical men can examine it for themselves.

My object has been to keep the main points of the argument in view, and to make it intelligible to all classes of your readers, and in this I hope I have succeeded, and should you or any of your readers be able to furnish me with the exact weight of the boilers* of the British Queen, and the space they occupy, with any further particulars, I will in a future number enter more minutely into the subject, and illustrate by a few sketches my ideas of how the boilers on the Cornish plan should be set and clothed, and where the extent of surface I have spoken of is obtained; having no doubt that I shall be able to establish every point that I have advanced, bearing on the increased safety and economy of the plan proposed, and at no distant period see it carried into successful operation on a scale commensurate with the importance of the undertaking, and the vital influence which such an improvement would have on our political and commercial relation with all parts of the world.

Pimlico, April 4, 1840. A. S.

* The modification of Cornish boilers I propose to adopt has no *external* flues.

RAMBLES BY PHILOMUSÆUS.—No. 6.

THE SOANEAN MUSEUM.

The Soanean Museum is again open for the few months and days which its managers think necessary to afford the public. Three months in the year, and two days per week, are in these days thought enough—we wonder the trustees do not think of charging a shilling, it would be carrying out the *rococo* style completely. Why not take immediate steps for throwing it open? Take up the carpets, apply to the legislature for funds to enlarge the establishment, make the museum worthy of the nation, and the trustees will do honour to themselves and to the memory of the founder. They have, in Mr. Bailey, a talented and well-intentioned curator, with one only fault, that he is disposed to regard an establishment worthy of the public, as only to be conducted for the use of artists,

> "Who, born for the universe, narrowed his mind,
> And to party gave up what was meant for mankind."

Let Mr. Bailey, if he places any value upon the promotion of public instruction, urge the trustees to do their duty.

This year a catalogue has been produced, which, as a first attempt, is of course rather scanty in size, but we are bound to say that the matter which is given is highly creditable to the exertions of the curator. It beats the National Gallery affair hollow, and is superior to the antiquarian portion of the British Museum catalogue. Why is there not a catalogue at the East India Museum? We have only one objection, and that is to the price; we think that three pence would have been rather nearer the value than a shilling; it does much honour to Mr. Bailey; however, there are copies left on the tables for the public to consult, besides the more extensive catalogue *raisonné* of Sir John Soane, so that the officers are acquitted of the slightest intention of jobbing or keeping back information, although they may have erred in a matter of judgment. Indeed, the wish to give information, and the courtesy with which it is imparted, seem, from the example of the superiors, to inspire the lowest officers of the museum, and it were to be wished that, in other establishments, the same spirit prevailed among the attendants.

The list of trustees given in the catalogue is far from inspiring confidence in any one who knows anything of them; there is only one man, indeed, who can be regarded as an active friend to public improvement, for as to the others, they are many of them notorious sticklers for acknowledged abuses. The sooner the museum is put under more active and responsible management the better. While the present parties doze over their duties, the place will continue to be a knicknackery instead of a national institution, and Sir John Soane's weeds will be allowed to usurp the place of his laurels. What we require is a proper classification, sufficient space, and facility of access for students and the public.

Sir John Soane has left the place, like his own head, with all kinds of queer corners in it; but irrespective of his arrangements, we shall proceed to notice, under their several heads, some of the principal objects.

The picture gallery, by means of *moveable planes*, has, crammed into the small space of 13 ft. 8 in. in length, 12 ft. 4 in. in breadth, and 19 ft. 6 in. in heigth, as many works, according to the book, as would cover a gallery of the same height, 45 ft. long and 20 feet broad. Besides the works in these rooms, are others dispersed through the Museum, so that in all there are about fifty paintings and forty drawings, besides statues and bas reliefs in numbers. These works ought to be removed from the museum or sufficient accommodation provided for them, as they are much too valuable to be sacrificed in the present holes and corners. The collection of the English school is very fine, containing 37 paintings and 25 drawings by our first artists. Among these are 12 Hogarths, which cost nearly 2,500*l*. the Rake's Progress and the Election; the Snake in the Grass by Sir Joshua Reynolds; a Jackson, 4 Howards besides the Ceilings, a Danby, a Bourgeois, a Fuessli, a Bird, a Ward, a Durno, an Eastlake, 3 of Jones, a Hilton, a Flaxman, 3 Stothards, 3 Corboulds, 2 Calcotts, 2 Daniels, 2 Turners. Of foreign masters there are specimens by Raffaelle, 4 by Canaletti (and the *chef d'œuvre* from Fonthill), by Rubens, Paul Veronese, Watteau, Ruysdael (3), Ostade and Zuccherelli.

The collection of sculpture, marbles, casts and models both ancient and modern, is fine. The specimens of Flaxman's works are above 10 in number, and ought to be brought forward so as to form a collection of the works of this great artist, who has done so much for our progress at home, and our architectural reputation abroad. Among them are figures and bas-reliefs of Piety, Charity, Truth, Winged Victory, Tenderness, Resignation, Hope, The Adoration, Joseph's Dream, Adam and Eve, Michael and Satan, a Grecian Feast, the Shield of Achilles, Mercury and Pandora, the Golden and Silver Ages, Cupid, Psyche, Britannia, Marquis of Hastings, Warren Hastings, Lord Mansfield, Pitt, Michael Angelo, Raffaelle, Reynolds, Kemble, &c. The works of Banks are about ten; they include the sleeping girl, St. Peter in Prison, the Dying Patriot, Achilles, and Caractacus. There are also specimens by Michael Angelo, John de Bologna, Donatello, Rysbrack, Westmacott, Chantrey, Gibson, Baily, Rossi, &c.

The architectural department includes drawings, models of buildings, and of details, and wants only arrangement to form a collection in the highest degree valuable. Among the drawings are all those of Sir John Soane's works, and others by Piranesi, Zucchi, Bibiena, Campanella, Clerisseau, Pannini, Labello, Asprucci, Sir James Thornhill, Sir W. Chambers, Kent, Sir Robert Smirke, &c. There are busts of the following architects: Palladio, Inigo Jones, Sir C. Wren, Sir W. Chambers, Dance, and Sir J. Soane.

The antiquities and curiosities might be made to form a museum as useful to artists as the new rooms in the Louvre at Paris, to which the artist and the pattern-drawer might resort with the greatest advantage. The purchase of the Belzoni vase was a terrible satire on the mode in which our museums are conducted, and a worthy pendant of the Ægina marbles affair; Sir John Soane said that he was but too glad to give the two thousand pounds the British Museum refused. Among the miscellaneous objects may be mentioned, Sir Robert Walpole's tables, Napoleon's sword and portrait, the Napoleon medals, Peter the Great's pistol, Tippoo Saib's chairs, Queen Mary's table, &c.

CANDIDUS'S NOTE-BOOK.
FASCICULUS XV.

> "I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please."

I. The clever and pleasant writer, "Nimrod in France," (Colburn's New Monthly), says in regard to French Houses, "There is one essential in the construction of them, of which I cannot speak too highly, and that is their mortar. It appears almost to equal in hardness the similar preparation of lime and sand mixed with water, for which the Romans were so celebrated, and which for its powers of cement and its durability, we have not been able to equal by our system of admixture. Certainly the French mortar may justly be called *cement;* and it is well that it can boast of this superiority, inasmuch as French bricks are most inferior to ours, from want of skill and care in the burning of them. French houses, however, generally speaking, are miserably defective in their plans, both for convenience and comfort, nor does there appear to be a desire to improve their structure. A heavy tax on windows and doors would be a blessing on the country—at all events as far as it would relate to lumbago, rheumatism, catarrh, coughs, and sundry other pains and penalties which human flesh is heir to."

Perhaps, too, a heavy tax upon supernumerary windows would be a benefit in this country,—at any rate it would be so architecturally, since scarcely anything is more inimical to nobleness of aspect, to solidity of appearance, and to repose, or more productive of insignificance than windows crowded together in such a manner that the piers between them are not so wide as the apertures themselves. This is an exceedingly common fault, the ordinary practice in London house-building being to put three windows where two would be sufficient. The consequence is that one side of a room is nearly all window, with no space for other furniture than chairs or mere knick-knack tables; so exposed to the sun in summer time, that it is necessary to exclude it by blinds, and occasioning a cheerless uncomfortable look in cold and bad weather. While as additional agremens, may be mentioned, that unless the street be a very wide one, your front rooms are thus fully exposed to the full fire of your neighbour's eyes, of "the amiable people over the way" who most disinterestedly interest themselves in reconnoitring your *ménage* as far as they can penetrate into it; and who, of course, busy themselves in imagining what they do not see.

II. 'Marry in haste and repent at leisure,' is a proverb that mutatis mutandis applies to architecture,—both to architects themselves, and their employers, many designs being adopted without due examination, the consequence of which is that their faults and defects escape notice, until it is either too late or too expensive to correct them. Nay in some cases the faults are so exceedingly glaring that it is wonderful how the designs could pass muster at all,—or how any one, calling himself architect, could make up his mind to pass off upon his employers the barbarously crude ideas we so frequently behold. Happy is it for such people that their employers are not only ignoramusses, but most tasteless ignoramusses into the bargain.—And that tribe among professionalists are therefore quite right in exclaiming against amateurs and amateurship, since the more the public become enlightened, the worse must it fare with them. They ought to pray for blockheadly gullible patrons—persons who look upon architecture as an unfathomable mystery, which the initiated alone have any right to understand.

III. Where ignorance is bliss—but I need not repeat the rest of that very hackneyed quotation,—therefore observe that I have sometimes almost envied the blessedness of ignorance, as I lately did while walking with a friend from the country, in the Regent's Park, whose rows of paltry mock palaces called forth expressions of admiration from him, that, I presume, were perfectly sincere. To the shade of that miserable architectural sinner John Nash, they must have been a requiem, but to me, to have to listen to the praises of that consummation of paltriness, was hardly endurable. And yet my companion was a person of tolerably good taste in other respects, and what is generally understood by "a well educated person," though imposed upon by such arrant architectural balderdash as those same terraces are. It seems to me that most persons have not the slightest shame whatever in displaying the grossest stupidity relative to every thing connected with architecture; and why is it so, except because the notion has been instilled into them—would that it were flogged out of them!—that it is for architects, and them alone, to pretend to understand its principles, these latter being, by some curious jumble of ideas, supposed to be entirely *mechanical*, notwithstanding that architecture itself has got the name of one of the fine arts. I once fell in with a gentleman, who was hardly less than a Solomon in his own conceit and pretensions, and who nevertheless staggered me by the *candour* with which he confessed he never could comprehend the ground plan or section of a building, or understand what they meant! Notwithstanding which degree of gentlemanly or genteel and blissful ignorance of low mechanical matters, my Solomon could, I found, speak glibly and boldly enough 'by look,' passing his opinion upon buildings, of which it was very evident, although he did not care to make such confession, that he understood no more than he did of sections and ground plans. There are, I am afraid, too many Solomons of his kind among our enlightened public."

IV. In an article entitled "The British School of Architecture," Blackwood's Magazine, August 1836, it said that the fourteen columns of the intended Doric structure on the Calton Hill, are "even now the most imposing objects of the kind in Britain: they impress strangers more than any modern edifice in the island, and if the structure be completed by the munificence of donations or bequests, on the same scale of primæval magnificence, it will give to the Scottish metropolis a distinction beyond what any capital in Europe can boast." The scheme for that national monument is also warmly advocated in the New Edinburgh Review, April, 1823. It seems, however, that the Scotch are too poor to prosecute the undertaking any further, else no doubt their prudence would urge them to complete as speedily as possible a building that could hardly fail to attract a great many visitors to their capital. Nevertheless some of them have so much money that they make the most desperate efforts in order to get rid of it, for instance, that remarkably silly Lord, Lord Eglintoun, who had he given towards this work the thousands he expended upon his tomfoolery of a tournament, would have secured to himself a very different reputation from what he has now got. Nay even the good people of Edinburgh themselves would act more wisely were they to complete the building on the Calton Hill, before they think of such matters as the Monument to Sir Walter Scott, unless indeed they are of opinion that, notwithstanding his hundred volumes, he is likely to be forgotten by the next generation.—Not the least singular circumstance of all is that beyond its name being mentioned, there is no notice of the 'National Monument,' on the Calton Hill, in John Britton's 'Modern Athens,'—a very remarkable work by the by, if only on account of its exceedingly funny dedication to "My Dear Sir Walter."

V. 'What is your opinion,' said a friend to me, 'of Italian Architecture?'—When I know what you mean, was my reply, I can perhaps answer you, but you might just as well ask me what is my opinion of English literature, without particularizing any further, and I should tell you, perhaps that at the present day a great deal of it is most arrant slipslop, and another great deal confoundedly villainous—to wit the Newgate school of it. So too, in Italian architecture there is a vast deal of most horrible rubbish, and also much that is admirable and delightful. Between such men as Francesco di Giorgio, Sanmicheli, Balvassore, Peruzi, and Borromini, with a long et cæteri, the difference is incalculable,—as great as between Charles Barry and *Mister* Nash.—As for Palladio I freely abandon him to his admirers.

VI. Never need the country be put to expense for a monument to George IV., because, as long as it stands, Buckingham will prove a monument of his—dotage. And surely his taste—if he ever had any must have been quite in its dotage when he approved of Nash's designs for that unfortunate building. 'Tis a thousand pities that two old gentlemen should have laid their heads together to palm such a piece of architecture on the country. In one particular, indeed, it may be said to resemble Perrault's façade of the Louvre, inasmuch as it has coupled columns—*hoc Ciceronis habet*: but then even in that respect, it is egregiously more faulty, colmons in pairs being introduced into a prostyle portico, whereas in the other edifice they form lengthened colonnades. On the other hand, although the mode of columniation adopted for the centre portico is rendered more glaringly offensive, by there being only single columns in those at the ends of the wings. After all, defects of this kind shrink to nothing when compared with the insignificance, and the pettiness of manner which characterise the whole building.

VII. The York Column is a prodigiously blank affair altogether,—one excuse for which may be that it would have been a puzzling, and somewhat ticklish affair to introduce any kind of sculpture, because the most appropriate and characteristic symbols would have been a gaming-table and dice-boxes, in allusion to the exploits, the heroism, and the martyrdom of the Royal Duke. Yet if as a piece of architecture that pillar is any thing but admirable, it may be turned to admirable account as a warning, and it is devoutly to be hoped that nothing similar will now be perpetrated in Trafalgar Square; especially as there is no occasion whatever to make the buildings around it appear at all lower, or more insignificant than they now do; which would infallibly be the case should a "huge bully" of a column be erected in the centre of them.—According to the newspapers, however, it would now seem that the Nelson Column is to be begun forthwith, on the strength of subscriptions coming in, which may *perhaps* provide a statue for the top of it; if not, *tant mieux*, for then it must at all events prove a *capital* affair.—Or commemorating Nelson so flagrantly would it not be just as well to commemorate him *fragrantly* after the manner in which Delcroix has just *commemorated* a recent event by his 'Bouquet de *Noces* Royales,'—which it should be observed does not exactly mean Royal Noses, although intended to tickle the noses of gentility.—I am afraid that Delcroix is a sad wag.

VIII. According to a recent German writer who professes to enlighten his countrymen as to our national character, English people, especially those of *ton*, are exceedingly shy of Munich, whose noble buildings and treasures of art possess far less attraction for them than do the coteries and gaming-tables of such places as Baden-Badin. There is, it is to be feared a great deal of truth in this; yet hardly is it to be wondered at, if the same satirical writer be correct in the classified catalogue he gives of the kind of English who visit the Continent, for he states that out of every thousand, 333 are half-pay officers, 100 ruined gamblers, 20 cast off kept mistresses, (who affect to pass for patterns of virtue,) 48 'Greeks' on the look out for 'Pigeons,' 50 economists—political ones of course,—who adopt the prudent economy of getting beyond the reach of their creditors, 10 people of wealth and rank, who, by way of change, *ennui* themselves abroad pretty much after the same fashion they do at home;—to cut this formidable list short,—just one Englishman in a thousand, who visits the continent in order to gain information and improve his taste. Assuredly the picture is not a very flattering one,—doubtless much exaggerated, but correct or not says a very great deal, because it shows in what light we are looked upon by foreigners. The same writer sets us down as absolute barbarians in music, which he says, we only hypocritically affect to admire without the slightest feeling whatever for it; and if he does not censure our taste in architecture, it is in all probability because he does not touch upon that subject at all; else, I conceive, many of our moderns would have excited his bile, not a little. However, be our taste in architecture what it may, we cannot be accused of much hypocrisy or affectation there; for the public generally do not care even to pretend to know any thing whatever about architecture.—Where our buildings have been spoken of by Germans, it has seldom been in terms of commendation; and it would not perhaps be amiss, if some of our architects were to read a few of their comments, and make themselves acquainted with their opinions, for though they could hardly fail of being an exceedingly unpalateable, they might also prove a very salutary dose to them.

IX. It is astonishing what downright silliness and nonsense is frequently made to pass for argument. A notable instance of the kind occurs in the article Architecture in the celebrated Encyclopédie Methodique, where it is said "La colonne doit être ronde, parceque la Nature ne fait rien de quarré." The same mode of reasoning might be employed to convince us that the surface of walls ought to be rugged, and floors uneven, *because* nature does not make the face of rocks perfectly smooth, nor the ground perfectly solid and level;—or again that besides being round, columns ought to have a rough surface, resembling the bark of trees,—for we suppose it is to the stems of trees we must look for the prototype of the shaft of columns. Besides, if columns are to be made round *because* nature makes nothing square, would not that be an excellent reason for making the architrave round or cylindrical also, merely cutting away so much of the under surface at intervals as would be requisite for its resting firmly on the flat abaci of the capitals. This might be done; and according to such theory, it would be both correct and natural,—perfectly in consonance with the BECAUSE assigned. Nay, might we not say that the convex or pulvinated frieze frequently given by Italian architects to the Ionic entablature is formed upon strictly rational principles, namely, agreeably to the aforesaid BECAUSE. But then if columns are round, because, &c.—how happens it that the abaci of their capitals are square? —or are we to suppose that while Nature herself shapes the columns, she leaves her apprentices and journeymen to make the capitals, &c. as well as they can. The sober truth is, all such reasoning is mere rigmarole, and if no more rational and likely *because* can be found out, as I apprehend could be, it is not worth while attempting to offer any at all.

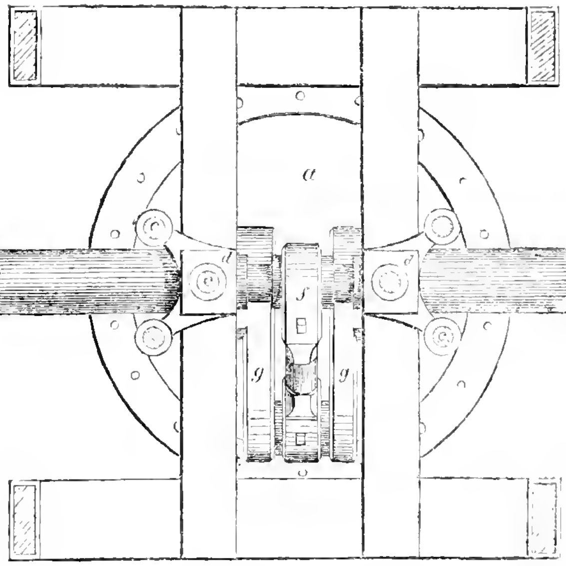
X. The real BECAUSE wherefore we make our columns round, is no other than because others have invariably done so before us; for which, again, there may have been more than one reason, and among the rest that of convenience, a circular shaft or pillar occupying less space than a square one of the same diameter, since the latter exceeds the former by the difference between the measure of its diagonals and its sides. Besides which, round pillars offer a greater contrast to walls and other flat surfaces, consequently tend to produce variety, while, at the same time, such form recommends itself as being, in some degree, more consonant to the prototype furnished by nature in the stems of vegetables and trees: and more studied and artificial also—more *recherché* than the other. Yet, although example and habit alone, independently of other considerations, cause us to regard the circular form as the most suitable, as well as the most beautiful, one for columns, it does not exactly follow that square ones are absurd—contrary to both beauty and reason, and that they ought never to be admitted at all. It is true no authority for insulated pillars of such shape, is to be met with in Grecian architecture; but then, neither does it supply us with precedents for antæ or pilasters continued along the front of a building, and many other things which are nevertheless practised without scruple, even where Greek architecture is professed to be closely followed. I do not pretend to say that square columns are so well adapted as others for general purposes, but there certainly are cases in which they might be introduced both with propriety and effect, either by themselves or in combination with circular ones, and either way would produce greater variety of design than can be obtained by restricting ourselves on every occasion to the use of round columns. Hardly will it be expected that I can explain myself more fully without sketches and cuts; yet I can mention one instance where I conceive a good effect might thus be produced, which is supposing it necessary or desirable to have two insulated orders, one above the other, forming, for example, a lower and upper portico, that below might have square pillars—not mere piers—of about the same diameter as the columns over them; whereby, not only would a monotonous repetition be avoided, but greater solidity would be obtained in the basement order.

XI. Would it be believed that a professed architectural writer, no other, in fact, than M. Quatremere de Quincy, speaks of "Vasbrug *ou* Væsbrug," under which queer metamorphosis he gives his readers the name of the architect of Blenheim. If it arises out of sheer ignorance, of the inability even to copy a word correctly when in print, what reliance is to be placed upon his accuracy. On the other hand, if it is merely the affectation of ignorance, it amounts to downright puppyism. The most ignorant Englishman would not say Boiler, or Vaultair (instead of Boileau and Voltaire;) at least, no English biographer would so designate those writers. But the truth is, that, in literary blunders, one Frenchman is at any time a match for two Irishmen. Among ludicrous instances we may find, "Hirzel an Gleim über Sulzer," translated "Hirzel sur le Gleim," with a note explaining that "Gleim est une petite rivière de l'Allemagne."! Poor Gleim! his poems must have been watery compositions indeed. Another Frenchman confounded Pressburg with St. Petersburg; and we now find Vanbrugh converted into Vasbrug or Væsbrug, which double mistake plainly proves it not to be an error of the press.

Rennie's Trapezium Paddle-wheel.—We understand Mr. Rennie has fitted the Lily, one of the boats plying between London Bridge and Hungerford Market, with his patent trapezium paddle, and that her speed is improved, as well as having done away with the swell caused by the ordinary paddle.

MAUDSLAY'S AND FIELD'S STEAM ENGINE.

Fig. 1.

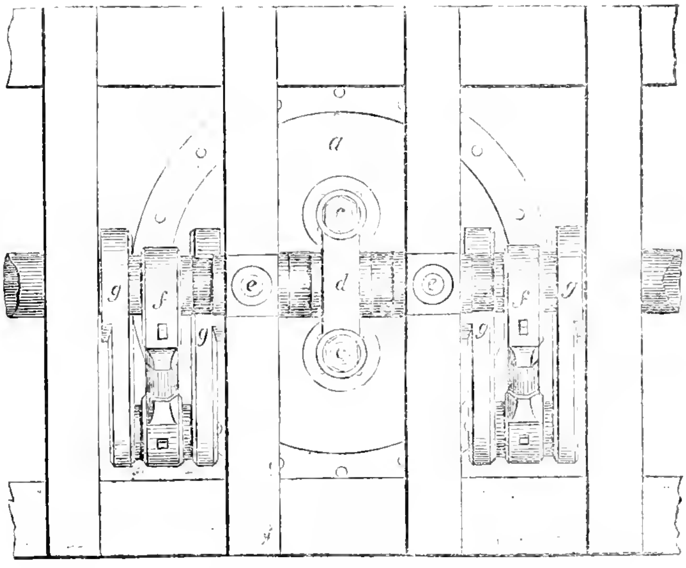


a, cylinder. *c*, *c*, *c*, *c*, the four piston rods. *d*, cross head. *e*, *e*, guide rods. *f*, connecting rod. *g g*, crank.

SIR,—Your March number of the Journal contains drawings and a description of Messrs. Maudslay and Field's patented improvements in marine steam-engines, and it is on the second feature of their invention I have presumed to offer a few remarks and suggestions. Moreover, it is generally observed, that when a person obtains a patent right for any invention, it no sooner publicly appears to the mechanical world, than it is followed up by a modification of some sort, that modification being more or less effective, costly, or practical; and it sometimes happens that by means of such modification, schemes which, as they occurred originally to the mind of the inventor, could never have answered, have, in their effect, exceeded his (the original inventor's) most sanguine expectation. However, the inventors in this case are practical men (the most extensive, perhaps, in the kingdom), and it may be thought presumption in me to offer anything which might seem an improvement on their schemes, but my anxiety for the advancement of mechanical science must be my excuse.

It will be seen from the engraving, and it is obvious, that the crank shaft is placed on one side of the piston rods, consequently the action of the piston cannot be communicated to the crank pin in a direct line

Fig. 2.



a, cylinder. *c*, *c*, the two piston rods. *d*, cross head. *e*, *e*, guide rods. *f*, *f*, connecting rods. *g*, *g*, *g*, *g*, cranks.

How far this may answer in practice I don't know, but the theory does not look well.

It will be apparent that the proper place for the crank shaft is in the line of the centre of the centre of pressure, or centre of the cylinder, and to obtain such place, I propose that there be four piston rods uniting in one cross head, as shewn in Fig. 1. The sectional area of the four rods would require to be very little greater than for two or only one rod, but of course there would be the additional friction caused by the enlarged surface.

The arrangement is sufficiently shown in Fig. 1, without any further description.

Fig. 2 is another plan for keeping the shaft in the same central position with only two piston rods; in this case there will require a double cranked shaft as shown, and of course two connecting rods.

By the arrangement in Fig. 2, cylinders of a minimum diameter may be employed.

Messrs. M. & F. may have thought of these methods of combination, or they may not; however, Sir, if you think the above worthy a place in your Journal, nothing would give greater satisfaction to

AMICUS MACHINARUM.

April 8th, 184 .

THE ASSIZE COURTS, LIVERPOOL.

SIR—The decision has just taken place with respect to the designs for the Liverpool Assize Courts, for which no fewer than eighty-five designs had been sent in on the 1st January, and the two lucky competitors to whose lot the premiums have fallen, are Mr. Elmes of London, and Mr. Grieg of Exeter. During the present week there is to be an exhibition of all the drawings at the Town-hall, Liverpool, but the time allowed for its being open is so exceedingly short, that very few professional men here in town, or at distance from Liverpool, will be able to avail themselves of it, more especially as no public notice beforehand has been given of it in the newspapers,—which certainly ought to have been done. Besides which, the same egregious blunder has been here committed,—or if not blunder, the same crooked and perverse policy has been here pursued, which has justly been animadverted upon in similar cases; namely, instead of preceding the decision, the exhibition is not allowed to take place until it is over, and all appeal from it rendered unavailing.

This surely might be remedied—at least might be attempted to be remedied by the Institute, who ought to draw up and publish a protest against such a highly injurious mode of procedure, and ought also for the future, in every similar case of the kind, that is, in a public competition for a building of any magnitude, and in which numerous members of the profession are likely to engage,—to address themselves formally to the committee—or, however, the presiding powers may be styled, and urge upon them the propriety and decency of granting a public pre-exhibition of the designs, and that too, for a reasonable and satisfactory time.

I certainly cannot help being of opinion, that the Institute have been culpably supine and remiss in regard to the very important matter of competition; and negligent both of the interests of architecture and its professors. What they have yet done towards advancing either, I do not know, nor have I been able to learn: probably, let their disposition and zeal be what they may, there are very few cases in which that body can exert itself with any effect; but that becomes only an additional reason wherefore they should exert themselves the more strenuously wherever they can: and in attempting to check the abuses of the present system of competition and establish a better one,—the Institute would, at all events, have public opinion on its side.

As regards the particular competition here mentioned, it does look rather odd that Mr. Elmes, who, but a few months before, had been the successful architect for St. George's Hall, should have obtained a second and still more expensive in the very same town, ere the first one has been fairly commenced. Indeed, it is rather singular that that gentleman should have chosen to enter a second competition immediately after succeeding in a previous one, unless he had particularly good reasons for anticipating success. However, it is to be hoped that his design will be found fully to justify his so extraordinary good fortune, and thereby remove the awkward impression now likely to be made upon those, who at present know only the curious fact itself, and nothing further.

I remain, &c.

April 27th, 1840. Q.

GREAT WESTERN STEAM SHIP COMPANY.

THE annual meeting of the Great Western Steam Ship Company took place on the 28th March, when discussions took place highly interesting, both in a professional and public point of view. The question in dispute is as to the propriety of the steps taken by the Directors in constructing an iron vessel of unparalleled size, and in erecting a manufactory for supplying the public with engines.

The first question is with regard to the size of the vessel, which, as we should state, is to be of 312 feet in length, 42 feet breadth of beam, 32 feet depth of hold, 2500 tons, and with engines of 1000 horses power. The reasons assigned for this step by the Directors are, the increase in stowage afforded by the use of iron, increase of power, and consequently quicker and more certain passages. To these reasons the objections are objections of expediency, and a question of expediency this must be considered in all its bearings, mixed up as it is with the circumstances of the company, and the objects for which it has been projected and carried into effect. It seems that the capital of the company is small, and the difficulty of raising funds at the present time is very great, and consequently, on that account, it is inexpedient to engage in large enterprises, for which the funds are insufficient, and from which the returns cannot be obtained quickly, nor depended on with certainty. What is wanted at the present period is to have more frequent steam communication between England and the United States, so as to make the use of steam habitual, and its advantages permanently manifest, and not to be looked on merely as a casual relief to the regular sailers. It is only in this way that the liners can be successfully competed with, for it seems the saving of time is still so little appreciated, that, by a reduction of fare, they have been enabled successfully to contend with the large steamers, and force them also to reduce their prices. The Great Western, also, at present, has rarely her full complement of passengers, and in the last three trips, there has been a considerable falling off, so that the necessity of a large vessel on the score of accommodation, evidently cannot be asserted. The Company will also, in the course of this year, be subjected to the competition of numerous steamers, so that they will be the more called upon to preserve the regularity of their communications, while they must necessarily have *speedily* a new vessel on the station, not only for the purpose of securing quick returns to the proprietors on their capital, but to prevent them from losing all profit in the event of the temporary or total incapacitation of the Great Western. On all economical grounds, therefore, the construction of a vessel of a larger size than the Great Western is clearly inexpedient, and indeed the proprietors, in giving their consent to the construction of an iron vessel, never contemplated any increase of dimensions. Supposing, even, that the experiment should be successful, the Directors will not even then be exonerated from blame, in having unadvisedly made such an attempt, so uncalled for by the circumstances, and highly perilous to the financial prospects of the Company. We now come to the question of the propriety in an engineering point of view, of engaging in such an undertaking, and we find that not only has it no example, but, from the highest authorities, it meets with no encouragement. We do not say that an iron vessel 312 feet long cannot be constructed, but we must say that it augurs considerable temerity to attempt it in the teeth of the opinion of those most competent to judge. The largest iron steamer which has been built is only of 400 tons, one sixth of the size of the proposed vessel, and Mr. Laird, the engineer, positively refused to contract for an iron vessel of only 1850 tons, so little was he disposed to proceed without some practical result upon which to base his operations. Mr. Ditchbourn, the eminent iron shipbuilder, of London, expressed himself to a similar effect before the Committee on Steam Communication with India. It must be further recollected that the Company's vessel, instead of being under the responsible control of a private builder, is being built in their own yard, so that, shou'd it prove a failure, the proprietors have no remedy. As if to heap experiment on experiment, the Directors have chosen to adopt a form of engine, of which the best that can be said is that it has not succeeded, if, indeed, it be not regarded as a total failure. Humphrys' Patent Engines will be found in another part of the Journal to have been patented as Mr. Broderip's, in 1828, by Col. D'Arcy, and how they ever came to be called after Mr, Humphrys, no one presumes to surmise. A pair of them was put on board the Dartford, built at Gravesend about four years ago, for Messrs. Halls, of Dartford, by Mr. Baulckham. The lines of the Dartford were very fine, and she had a very promising appearance; when, however, her engines came to be put on board, so far was she from justifying the predictions of her proprietors, that they were obliged to give up running her on the Thames, after she had been beaten by most of the boats on the river. She was then being also found to be dissatisfactory, she has been repeatedly offered for sale, without success, at less than half price, and may now be found in the East India Docks with a broom at her masthead. Both Maudslay and Seawards refused to construct engines on this principle, and Mr. A. Mornay has written a paper to show that the trunk engines are good for nothing at all. Mr. Brunel, in defending the character of the Dartford, very gravely assured the Bristolians that she had beaten the "City of Glasgow" by two hours in going to Portsmouth, a fact, which, if true, it is very fortunate for him that he did not state in London, for here the City of Glasgow is a byeword for slowness, a kind of *Regulator*, by which all the other steamers go. Having said thus much, we shall now proceed to show, by a few calculations, the justness of our remarks.

The engines are to have cylinders of 10 feet diameter and 10 feet stroke, and thus, according to the usual computation of 7 lbs. effective pressure on the square inch of the pistons, assuming their speed to be 240 feet per minute, would be equivalent to 1151·5 horses power, if of the ordinary construction; but as they are to be made with the trunk, half the transverse section of the latter must be deducted from the area of the piston, (say one-fifteenth of the area of the piston), by which the nominal power of the engines is reduced to 1075 horses power. They are expected to weigh, without the boilers, one third less than common engines: we may then fairly assume that they will weigh, with the water in the boilers, 800 tons.

It is difficult to imagine the motive which has induced the Directors to cram this *enormous* power into their intended vessel, the proportion of power to tonnage being about what is allowed to small boats; for by so doing they forego the chief advantage which large steamers possess over small ones for long voyages. The natural consequence is that the vessel will be able to carry little or nothing besides the requisite fuel for the voyage across the Atlantic.

The whole area of one of the pistons is 78·54 square feet, from which if we deduct one fifteenth for the half area of the trunk, we shall have for the mean area acted upon by the steam, 73·3 square feet. The mean capacity of one of the cylinders is, therefore, 733 cubic feet. If we suppose the diameter of the paddle wheels to be 36 feet, the vessel cannot be expected to advance more than 83 feet 9 inches for each revolution, which with 12 revolutions per minute, would give a speed of nearly 10 knots an hour, and the voyage from Bristol to New York would require the wheels to make about 220,000 revolutions. For this 880,000 cylinders full of steam will be used, but as under favourable circumstances the steam is to be used expansively, we will suppose it, on an average, to be cut off at half stroke during one half of the voyage, and used at full pressure during the other half. On this hypothesis only 660,000 cylinders, full of full pressure steam, will be expended, exclusive of waste. This is equivalent to 483,780,000 cubic feet of steam, to which if we add 10 per cent for waste, the total expenditure of steam will be 532,158,000 cubic feet. We understand the steam is not to be used at a higher pressure than 4 or 4½ lb. above the atmosphere; at the former pressure one cubic foot of water is required to generate 1356 cubic feet of steam, so that to produce the above quantity of steam 392,147 cubic feet of water must be evaporated.

Mr. Armstrong in his work on the Boilers of Steam Engines, gives 10 lbs. of coal as the quantity requisite to vaporize one cubic foot of water, but as the usual allowance for marine engines is only 9 lbs., we shall adopt this as the basis of our calculations. On this hypothesis the consumption of coal during the voyage will amount to 1580 tons nearly (say 1600 tons, to allow for emergencies). At the commencement of the voyage the resistance of the water to the vessel's motion will be of course greater than when she is light; and by the consumption of some of her fuel, the engines will not be able to make their full number of revolutions; and it cannot be doubted that under these circumstances a greater amount of fuel will be consumed in the same distance than when going at full speed, so that it will be scarcely safe to take less than 1600 tons on board at Bristol, particularly as the passage out may be reasonably expected to be prolonged by adverse winds, which do not occasion a reduction in the consumption of fuel *proportional* to the diminution of the vessel's speed; for it is clear that, to obtain an equal resistance with fewer revolutions of the paddle wheels, the floats must slip more through the water, and consequently the progress of the vessel must be less for each revolution of the wheels than when she has no contrary wind to contend against. Now the quantity of fuel consumed is proportional to the number of strokes of the engines, therefore the consumption in a given distance, although not proportional to the time occupied, will be greater when the speed is reduced by adverse winds than otherwise.

The directors have announced that the vessels displacement will not exceed her tonnage, or but slightly, and that she will not vary in immersion between Bristol and New York more than 2 feet 6 inches. attempted to be run to several places on the south coast, but this Now the weight of the hull, masts, yards, sails and rigging, boats, cabins, fittings, &c. cannot be safely estimated at less than 1100 tons

The engines and boilers with water - - - - -	800
Fuel - - - - - - - - - - - - -	1600
Making altogether (without any cargo) - - - -	3500 tons,

which is already 1000 tons more than the measured tonnage of the vessel. Her draught of water will, therefore, be 3 feet 6 inches, or perhaps 4 feet more than it is expected to be.

On a rough computation we estimate that the vessel's draught of water will vary about 5 ft. 6 in. during the voyage, by reason of the consumption of 1500 tons of coal: and for this reason, as well as on account of the immense power of her engines, the paddle wheels cannot be made less than 36 feet in diameter, with 32 floats on each, measuring 15 feet in length and 4 feet broad. With a less diameter a speed of 10 knots an hour could not be hoped for with 12 revolutions per minute, even in calm weather, and with smaller or fewer floats the engines would probably over-run their speed, when the vessel was lightened by the consumption of the chief part of the coal. If, therefore, with the floats immersed 4 feet, the wheels make 12 revolutions per minute, and the vessel attains a speed of 10 knots, as assumed above, the engines will be brought up to about 7 or 7½ revolutions at the beginning of the voyage with 1600 tons of coal on board, which would immerse the floats 9 feet 6 inches instead of 4 feet, and the speed of the vessel would most probably not exceed 5¾ to 6¼ knots.

As regards the expense of the new vessel, as estimated by the Directors, we will call attention to the fact that the price per cwt. of angle iron, plates, &c. increases with their weight, and, if the "Rainbow" cost 60*l*. per ton weight of iron (which is the fact), it is not unreasonable to assume that the new vessel will cost 80*l*. per ton; but taking it at 70*l*. only, and the weight at only 650 tons, the hull alone will cost - - - - - - - - - - £45,500

Adding to this for masts, yards, cabins, stores, &c. -	15,000
And for the engines at 35*l*. per horse power - -	35,000
We find for the cost of the vessel - - - -	£95,000

which exceeds her estimated expense by 20,500*l*., irrespective of all preparations, accessories, buildings, tools, &c.

The tools are to cost 30,000*l*., out of which we find by the last report that 19,000*l*. was paid, and out of the cost of the vessel 6,800*l*., leaving still to be paid for the vessel - - - - - £ 88,700

for the work shops - - -	11,000
By the same report there was expended - - -	105,500
Required to pay debts due - - - - -	11,000
Making in all - - - - - - - - - -	£216,200

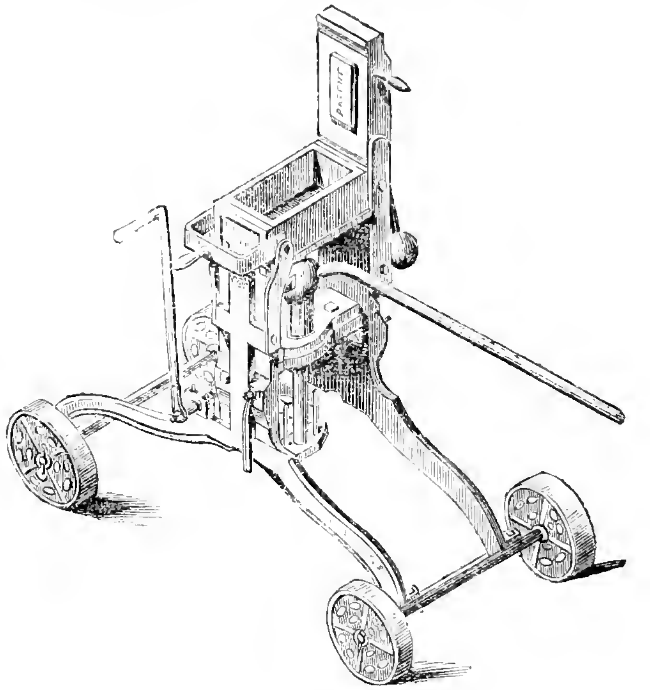
The total number of shares taken falls short of 1,900, and assuming them at that number, and that all calls will be paid, the gross capital of the Company amounts to 190,000*l*., or 26,200*l*. less than the inevitable disbursements before the completion of the new vessel. Besides this there will be the rent of premises, clerks' salaries, expenses of management, &c. during the term of completion, which cannot be safely estimated at less than two years.

Having shown the temerity with which the directors have acted, both in regard to the size of their vessel, and the engines by which it is to be worked, and having proved that it is inexpedient and injurious, we have next to consider one of the most outrageous propositions that was ever suggested to a public company, that of setting up a factory for making vessels and engines. Without any attempt to ascertain on what terms the vessel and engines might have been constructed by contract, the directors have themselves determined to execute both, and have accordingly already laid out £20,000, being *one fifth* of their capital, in the purchase of leasehold property! in digging docks! and in buying machinery! and as if it were not enough to waste the limited capital of the unfortunate shareholders in such speculations for their own uses, but, as if to add the climax to their proceedings, they actually propose to organize a regular factory for making vessels and engines for whomsoever will buy them. With a capital totally insufficient for the legitimate objects of the Company, and having unadvisedly engaged in a most hazardous and unwarranted speculation, the directors waste the resources of the shareholders on objects which it will require a long time to make available. As to how they propose to find money for finishing this vessel, which will certainly cost much more than their estimates, or for carrying on their extraordinary operations, no one can conceive, unless they are to bring half shares into the market to divide equally with the original proprietors. To aggravate the injury in particular cases, they are literally employing the money of Mr. Acraman, the great engineer, in competing with himself. With regard to the legality of their proceedings, it requires very little knowledge of law to be aware that it is only under a new deed of settlement that the directors can carry out any such plans. As to the propriety of engaging as rivals to private manufacturers, public opinion is too strongly against such a practice to render any further comment necessary, while, as concerns the shareholders, if this departure be allowed from their original plans, there is no reason why the Directors should not set up chain-cable works, rope walks, sail lofts, machine biscuit bakeries, or anything connected or not connected with shipping,—they may engage in banking, life assurance, or any pursuit.

We cannot, therefore, but be of opinion that, on every point, the Directors are not only totally unwarranted in the course they have pursued, but are open to severe reprobation for their imprudent management of the affairs of the shareholders, whose property must, by such proceedings, be rendered more unsaleable than it is even at present. The future operations of the Company are in every way embarrassed, both by the mismanagement of the capital, and the heavy charge that must be created by such a lumbersome vessel and expensive establishment, which must be kept up, whatever may be the revenues of the Company. The report which recommends and justifies the course adopted, is of a most fulsome and trumpery character, with the stamp of official paternity strongly marked; the self-laudation is too apparent to be disguised, and, like on passing the line, every one of the novices is abundantly bedaubed with the glittering slime of the concoctors. The phraseology is as rich as the matter of which it is the vehicle, and renders the whole affair still more sickening. We do not think it necessary to give the report any lengthened examination, or we should waste the time of our readers and our own in exposing this tissue of egotism and presumption. Among other information which we see with regret is, that the Company have been compelled to accede to the grievous demands of the Dock Company, and pay a large sum for docks their vessels can never enter. They were obliged to take off the paddle-boxes of the Great Western to get it into Cumberland Basin, and, as if to make the difficulty greater the new iron vessel will be seven feet wider. This is making a man too large for his house with a vengeance, and we very little question that the Great Western Directors will, in time, in their zeal for the interests of Bristol, make their vessels so large that they will not be able to get up to the city at all. The experience and observation of the Directors and officials is very much praised, but if we are to judge by one example, we fear a little too much. They coolly state that a modification of the Great Western's paddle-wheels has been made, founded upon the results of accurate observations during her voyages, which modification, if we are informed rightly, so far from being an improvement, has had the effectual result of reducing the speed of the vessel. The *sang-froid* with which they mention the superiority of themselves and their yard is admirable; it shows a becoming obliviousness of the Maudslays, Millers, Boltons, Acramans, Seawards, Fawcetts, Napiers, &c.; their confidence in the estimates and opinions of the most eminent manufacturers is rich, the persons answering to this description are, the patrons of the Trunk Engines, Messrs. Halls, of Dartford, and a most eminent and practical man, in whom they put their trust, is Mr. John Scott Russell. Well may the directors talk about its being for *the interest of the shareholders that their singular appliances should be directed to manufacture and repair for other parties*, if they believe that any one can feel any confidence in their ignorance and quackery. We leave this subject with an earnest entreaty of the shareholders concerned to look about them, and get their affairs out of the hands by which they are at present mismanaged, or the end of the experiments will be the total ruin of their property.

Steam-Plough.—A trial was lately made in one of the fields on the estate of Fossil, near Glasgow, of the steam-plough, intended for the cultivation of the sugar lands of British Guiana. This trial was completely successful, and gave great satisfaction to the numerous party who witnessed it. The field was laid out similar to those in the colony, which have canals on each side running parallel with one another. The machinery consists of two iron boats, one containing a small high-pressure steam-engine, with a drum, round which the endless chain or rope is coiled, and the other a reversing pulley, by means of which the chain or rope is extended, and allowed to work whichever way is required; the ploughs are attached to this chain, and made to work backwards and forwards with great rapidity and accuracy. Mr. MacRae, whose long residence in the colony, and great practical experience of the working of sugar estates, had directed his attention, for a considerable time past, to the great and absolute necessity of employing some other power to supersede cultivation by manual labour, invented the steam-plough, which was executed by those enterprising engineers Messrs. Thomas Edington and Sons, Phœnix Iron-works, whose great ingenuity in constructing and designing the various parts was very much admired.—*Glasgow Courier.*

BAKEWELL'S PATENT BRICK MACHINE.



This machine is strong, of simple construction, and made of cast iron. The mould for receiving the brick is fixed at the top, the inside being accurately ground, and the bottom made to slide freely up and down, when operated upon by the screw and lever underneath; the top is made with a counterbalancing weight by which it is easily opened on withdrawing the catch that secured it. A winch is likewise connected with the underside of the mould to raise the brick after it has been pressed.

The process for pressing the bricks is as follows:—The bricks when half dried are placed in the mould, the lid closed and secured, the bottom is then forced up with a pressure of from 4 or 5 tons, by means of the screw acted upon by the horizontal lever. The brick is then raised out of the mould by simply forcing back the winch and removed by a boy; the bottom is then lowered by its own gravity, and is ready for another operation: by the aid of this press, between two and three thousand bricks may be pressed in a day with the labour of one man and two boys.

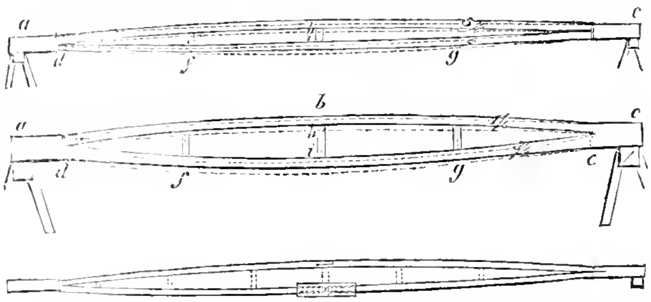
It will be seen that this machine does not profess to make the bricks, but is intended to improve them when made; this it accomplishes in a superior degree; the bricks when turned out of the mould have the sides smooth, and the arrises perfect and parallel, and when burnt, they retain their form, and are of great hardness; they are consequently, well adapted for facings of buildings and paving, as the joints can be laid quite close and regular, the bricks being all of an exact size: they are equally desirable, on account of their extreme hardness and near impermeability to water, for engineering works; particularly for arches and abutments, viaducts and bridges, foundations, retaining and dock walls, and other works requiring great resistance. The press may also be used for quarries or fancy bricks, which can be pressed to almost any form by merely changing the mould. This press has been in use for many years, more particularly in the midland counties where several public buildings have been faced with these bricks, which gives them a very superior character, far surpassing the bricks commonly applied to that purpose; and although the machine has been used very extensive by Mr. Rhodes, it is not much known in London. The front of Bielefield's extensive Papier Maché Works, in Wellington-street, are faced with bricks of this description. We understand that several parties are now in treaty for licenses, and that the introduction will shortly become very general. The extra cost of the bricks will be from five to seven shillings per thousand;—a sum comparatively small, for the superior quality of the brick, which cannot add very greatly to the cost of the building when used for facings only. The miserable looking brick buildings at the several railway stations, would have been much benefited by them, as they now exhibit generally a very mean and stable like appearance, which a clean well coloured facing brick, at but small cost, would have been easily prevented. We with pleasure recommend the attention of the profession to this important patent, which can be viewed at the proprietor's office, Adelphi Chambers.

ON TRUSSED BEAMS.

Invented by Herr Laves *of Hanover, read before the Royal Institute of British Architects, on Monday, March* 20, 1840, *by* T. L. Donaldson, Esq., Fellow.

Mr. Laves took a beam of fir 40 ft. long and 9¼ in. deep, and 7½ in. wide, and supported at the ends. He gradually loaded it with 100 lbs. at a time, and found that when it had 1700 lbs. it deflected 5¼ in. He took a beam of the same dimensions and cut a horizontal slit to within 3·6 from each end, making the upper portion 5 inches deeper and the latter 4¼ ; he put iron straps at the ends, bound tightly round to prevent the slit from extending—he then forced the upper and lower part of the beam asunder by driving in blocks or wedges, until they were as wide apart as half the depth of the beam—he supported the beam at the ends and found that when he had gradually loaded it with 100 lbs. weight as before, until it bore 1700 lbs. it only deflected 3½ in., being 1¾ less than the solid beam. He then separated the slit apart 9¼ inchei or equal to the whole depth of the beam, and gradually loaded it until it bore 1700 lbs., when it deflected 2¼ or 3 inches less than the solid beam, and 1¼ less than the former. He then widened the opening of the slit 13⅞, or equal to a depth of 1½ of the solid beam, and loaded it in like manner with 1700 lbs., it deflected only 1⅜ inches, being 4 inches less deflection than the solid beam. (See Fig. 1.)

Figs. 1, 2, and 3.



He then took pieces of fir 50 in. long, 2 in. deep, and 1 in. wide; one was left solid, two others were slit so as to make the upper part 1¼ inches deep, and the under ¾ in., one piece having the slit half the depth of the beam apart, the other ¾ of the depth apart. See fig. 2.

It will be perceived that the principle of this system consists in the combination of the two chief forces of materials, that is resistance to compression, and resistance to tension.

Resistance to compression is the one employed from the remotest periods in the construction of arches and vaulting, and requires great masses of materials; and resistance to tension has more lately been employed, at least in Europe, for the construction of suspension bridges by the application of chains, and requires less materials than the other principle of compression, but frequently the insertion and use of chains is obtained with difficulty, and produces vibrations and sensibly felt undulations.

These inconveniences have led to the application of this system. It will be perceived that the under line or chain attached at the two extremities of the upper curved line acts with positive force that of tension, which is the greatest possible force of materials varying from 10 to 20,000 lbs. on the square inch of the transverse section in various woods used in construction, and from 20 to 100,000 lbs. in metals.

The upper line or beam acts by relative force that of compression, and serves to prevent the lower line or chain from contracting the two extremities.

The lower line or chain hinders the upper line or beam from pressing out at the extremities.

The supports and braces serve to unite the upper and lower lines or beam and chain together, and then two forces neutralized form a complete whole, which sustains itself, and can neither thrust out nor draw in.

It is to be observed—1st. That the force of the chain is dependent upon the depth of the versed sine, and that the lower it is beneath the horizontal line or chord of the arc the stronger it will be. Arches of solid construction require a rise of 20 or 15 ft. for the springing of the arch to the soffit of the key stone, in a span of 100 ft; but the chains in this system, if they have a rise or versed sine equal to 4 ft. 2 in. in a span of 100 feet, the force of the chain reduces itself to one-third of the absolute product—if the rise or versed sine equal 6 ft. 3 in. in the same span of 100 ft., the absolute force could be reduced a half.

Observe 2dly. That the upper line or beam, on account of the elasticity of the materials, ought absolutely to have the convex form as in the diagrams, in order that when considerably loaded, the lengthening of the under line or chain by tension, and the shortening of the upper line or beam by compression, may not reduce the upper curved line to an horizontal one, beneath which it would no longer serve by resistance to the statical equilibrium of the construction.

We observe, 3rdly, That the method of tying together the extremities of the curved lines will depend on the materials employed, and must be calculated according to the weights that they will have to bear.

Such are the general principles of this system when applied in a horizontal direction.

We will now consider its application in a vertical or upright direction, and when used obliquely.

It is obvious that the resistance of a story post or stay, whether in wood or metal, increases in a fixed proportion according to its thickness.

For wood—the pieces of wood are sawn as before described with one cut, or two cross cuts to within a certain length of the ends, and these tied together by bolts or straps of iron. The cuts are then forced apart by wedged blocks and kept in their places by bolts or straps of iron.

For iron—by connecting together at the ends, two or more bars of iron, and separating the bars by wedges or pieces of iron, or iron rings.

The proportions and number of the different parts as chains, stays, posts, &c., depend upon the purposes to which they may be applied, and must of course be calculated accordingly by the architect.

The most simple practical application of this system is for the purpose of wooden bridges, and the upper line or beam may be materially strengthened, and the combination stiffened by the introduction of stays and braces.

If the span of the bridge exceed the length of one beam, two may be taken, sawn at one end only, and connected by two scarfing pieces, into which they must be fitted with notches, and bolted or strapped together so as to prevent their separating.—See fig. 3.

In those parts where the ends of timbers abut upon any joints or other timbers, it will be expedient to interpose thin plates of copper or iron, in order to prevent the but ends from driving by the force of compression into the beams, which would cause a sinking.

For occasional purposes or military operations it may be useful to adopt the same system applied to rough trees, which would even be picturesque and useful in parks and gardens—and by connecting the forked branches of two trees, to produce a combination which would answer every purpose.

For all the bridges hitherto described, it will be sufficient that the versed sine of the lower arc or chain equal $\frac{4}{100}$ or $\frac{1}{25}$ of the span. This is very moderate, for a beam requires $\frac{1}{100}$ or $\frac{1}{20}$ of the span, and bridges or arches of masonry or solid construction, a rise of $\frac{15}{100}$ of the span.

If the banks of a stream be too wide apart to admit the adoption of this system in one span, it will be necessary to have intermediate piers or columns, and to form a succession of framings tied together with iron straps, or constructed in cast iron.

If the bank of a river be too little elevated above high water mark, or if it were requisite to give greater height in the middle of a series of arches, in order to admit the passage of vessels, the lateral framings admit of a gradual fall to the banks without affecting the stability of the framing.

Various bridges upon Mr. Laves principle have been constructed.

1. One in oak at Hanover for foot passengers—the span 100 feet, width 12 feet—cost about 112*l*.

2. One in oak over the Nette river at Dernebourg, near Hildesheim—span 60 feet, breadth 15 feet, it being for carriages—cost about 70*l*.

3. One in oak for foot passengers, and a water pipe at Dernebourg, near Hildesheim—span 30 feet, breadth 10 feet—cost 26*l*.

4. One in fir for foot passengers over the Eger at Elnbogen, in Bohemia—length 36 feet, width 5 feet—cost 50*s*.

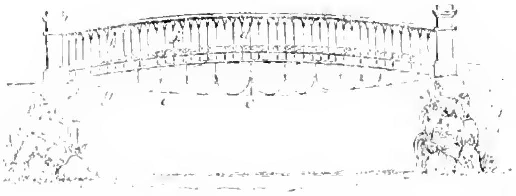
5. One in fir for carriages over the Eger at Altsaltel, in Bohemia, in two lengths, supported in the middle or junction of the two—total length 126 feet, width 15 feet—cost about 100*l*.

6. One for carriages in wrought and cast iron, in the Royal Park of Herrenhausen, near Hanover—length 83 feet width 20 feet—cost about 550*l*., comprising the wood paving for the carriage way.

Besides others at Salzau, near Kiel, in the Royal Park at Hanover, and one for the Count Munster at Dernebourg, near Hildesheim, varying from 22 to 42 feet span, and constructed in iron at a very moderate cost, all of which are described in Mr. Laves' pamphlet.

Figure 4 explains the construction of an iron bridge over a river, the upper line consists of hollow cast iron cylinders united by bands of wrought iron. The chain is of wrought iron, and the rings may be made either of wrought or cast iron. The hollow cylinders are for the purpose of producing lightness in the upper line, which is essential.

Fig. 4.



The application of this system to roofs and floors is extremely economical and useful, and by simple modifications serves for the covering of large spaces without any intermediate point of support, and presents this further advantage, that from its vertical pressure it requires no other support than walls of moderate thickness.

When applied to floors, bridging joists will remedy the inequality of surface in the beam itself.

In roofs of large span the posts may be continued up so as to receive the purlins, and when continued downwards serve to hold up the ceiling, whether flat, or vaulted, or mixed.

The principal rafters of a roof may derive considerable strength from being treated in the same way as in fig. 2, which combination is calculated for roofs of 50 feet span; by this arrangement of the principal rafters at distances of 10 feet apart, no intermediate stays or posts are necessary to support the purlins, so that a fine clear span space is left in the roof. Here the tie beam is slit according to Mr. Laves' system, and acquires sufficient strength to support itself without being tied up to a truss.

Mr. Laves has applied this principle to various roofs.

One in iron over the kitchen in the Royal Park at Hanover; one in carpentry of 50 feet span, over a barn belonging to the Baron of Wangenheim, at Wangenheim, near Gotha: and likewise one at Hersum, near Hildesheim, and over the scenery magazine of the theatre at Hanover.

The painting room of the scenery in the theatre at Hanover has the slope of the roof formed by rafters, slit down the middle and kept apart —the span 38 feet in the clear, and length 74 feet.

Another application of this system is to large ladders, which when very long, whether used for fires, to scale batteries of beseiged towns, or to board ships, had the inconvenience of being cumbersome, difficult of conveyance from one part to another, so that they could be managed only by numerous assistants; hence they were comparatively little serviceable for the end proposed, and frequently not able to be brought in time sufficient to render the assistance required.

In the case of ladders each of the sides of the ladder is sawn in two to within a certain distance from the ends, which are bound together by iron bolts or straps. The intermediate stays, used to keep open the cut, also serve to combine the forces of the two parts, and being continued are useful to receive a side cord, as an additional security to a person ascending or descending. A ladder so constructed may be placed in a horizontal position, and is sufficiently stiff to act as a temporary bridge or scaffolding, from the window of one house to that of another on the opposite side of the street, or from one vessel to another.

If the chain be formed of iron wire, it would answer the purpose equally well, and be tighter.

If it be desirable to place the ladder in a slightly inclined direction, without any immediate object to rest against, two props or supports should be placed against the uppermost rail or round, which, to avoid oscillation or bending, should also be composed of slight pieces of timber, sawn down the centre, kept apart by small intermediate blocks, and bound at the ends as already described.

Mr. Moore's patent Plan for Feeding Furnaces, &c. Fires, for the Consumption of Smoke.—Mr. Moore proposes to have the grate-bars hollow semi-cylinders, with the concavities upwards. The fuel is put into a similar semi-cylinder scoop capable of sliding within either of the grate-bars, and being thrust in from end to end, is turned half round, and then withdrawn, leaving the fuel in the same cylinder bars, which is ignited from the burning coals above. The patentee says he has never found any difficulty in the scoop's forcing out the burnt fuel already in the grate-bars, and that the fire, by this contrivance, never wants any more stirring than is given by the introduction of the new fuel. Of course, the smoke is ignited and consumed by passing up through the red-hot coals above.—*Railway Magazine.*

STEAM NAVIGATION.

The bold front shown by the Engineers and Steam Ship Builders, has shaken Mr. Labouchere's confidence in the propriety of the measure of which he is the official custodian, and, like a prim old maiden distrustful of the legitimacy of the little darling which she had been parading with so much delight, is prepared to modify his trust. He expresses his hope that the measure, as modified, will contain nothing distasteful to the engineers, and appears extremely anxious not to go at once into a discussion on the grievance. We hope that the engineers will think as we do, that this is not a question to be compromised, nor is it prudent to allow such a threatening attack to pass without notice, for the animus is too evident not to render the introduction of the bill certain, whenever its concocters can watch a fitting opportunity; we therefore warn all concerned to be prepared at a moment's notice to oppose this obnoxious measure.

We have felt ourselves strengthened in the course we have adopted, in the consideration of this momentous question, by an able memorial which was addressed to Congress in February last, by the proprietors and managers of steam-boats in the United States, who, so far from concurring in the wisdom, even of the modified code brought forward as an example by our commissioners, boldly declare its injustice and inefficiency. Fearless of al. the exaggerated horrors of newspaper paragraphs, and of the facts and pseudo facts raked up by government authorities, they claim at once for steam navigation "a degree of security in the transportation of persons and property, which has not been equalled by any other known means of transport or navigation." They assert, also, that the present degree of security is due to no interference of government with mechanical arrangements or prudential management, or to the enforcement of novel and severe principles of legislation, but to the inventive and discriminative powers, prudent foresight, and persevering spirit, of those engaged in that important branch of public enterprise. The memorialists go on further to urge,

"That certain enactments of peculiar novelty and severity, found in the act of Congress of July, 1838, are calculated to bear harshly and oppressively upon the owners of steam vessels, and thus to affect injuriously, this important branch of our navigation. These enactments, instead of furnishing encouragement for a just and generous rivalry, in bringing steam vessels and their machinery to the highest possible state of security and perfection, have, unfortunately, in the view of your memorialists, a direct tendency to deter men of prudence, capacity and property, from further connexion with this business; who are unwilling to submit to implied reproach and degradation, to unwarranted hazards, and to the loss of rights and privileges which are guarantied to all other persons engaged in a lawful calling. Your memorialists refer more especially, to the clause which deprives them of the universal legal protection common to every civilized country, by unjustly construing, in the event of any serious disaster to life and property, the presumption of innocence into *prima facie* evidence of guilt: and they respectfully request of your honourable body, that a provision which is so much at variance with their fundamental rights and privileges as American citizens, may be repealed.

"It is with painful regret that your memorialists have noticed an attempt to procure a broader and more mischievous application of this unjust principle, by means of proposed additions to this law; and they respectfully ask of Congress to be protected from such proposed aggravations of the already severe and relentless doctrines of the common law as it now governs the responsibilities of common carriers; and which, if enacted, must tend to destroy every just inducement for longer continuance in a business which is subjected to such unprecedented liabilities to loss and ruin. These extraordinary hasards and liabilities, it should be noticed, will not pertain to our competitors under a foreign flag; and our citizens may thus be virtually excluded from navigating the ocean by steam. Your memorialists would further remark, that if with the best knowledge possessed by this or any other country, this species of navigation be deemed too hazardous for the public safety, they deem it more just and honourable to submit to its entire prohibition.

"Your memorialists believe that few opinions are more erroneous than that which ascribes to the provisions of the existing law a generally increased safety for persons and property carried in steam boats. This may appear from the many accidents or disasters of a serious character which have taken place during the short period in which this law has been in force. The number of these accidents on the western waters during the last year is stated to have been forty; which may serve to convince Congress that the appropriate remedies for these disasters are not furnished by this law; and can be found only in the increasing practical knowledge and skill of those persons who are engaged in the construction and management of steam vessels.

"Your memorialists do not seek to escape from any just responsibilities in conducting this important business. On the contrary, they feel bound to furnish every reasonable guaranty for safety to life and property which human foresight and prudence may be able to afford: and it is for the purpose of furnishing these guaranties in the most direct and practical manner, that they further respectfully but earnestly request, that Congress will call to the aid of its committees, to whose protection this important branch of navigation has been intrusted, the information and experience of some of the individuals whose lives have been devoted to its improvement and practice from its earliest origin in this country:—in order that practical knowledge may form the basis of legislation upon a subject which affects more or less directly the interests and business of, probably, a great majority of the American people."

The memorialists here declare, unequivocally, that such restrictions, instead of producing improvement, must retard the progress of science, and check the employment of capital, without, at the same time, ensuring the objects, which they are intended to effect. To show how little desirous they are of concealing facts, and how little daunted by the exaggerations of their opponents, the memorialists append to their pamphlet Messrs. Pringle's and Parke's concoction of one hundred accidents, which have occurred to English steam-vessels, leaving the ungullible portion of the public to form their own comments on the case. These commissioners remind us of the quack who attempted to frighten the old lady out of her tea, by assuring her that it contained a millionth part of prussic acid, and that it would certainly carry her off. "A very slow poison," said she, "for it has been eighty years about it already." Facts show that the loss of life by English steamers, in the very worst year, 1838, was not one twentieth of the number annually lost in sailing vessels, and the amount of property not one fiftieth. On the coasts of the United States last year, above 400 sailing vessels were lost, and 1000 lives. On the New York waters the contrast is as strong.

"Those who have laboured to inflame the public against these unfortunate men may well be reminded, that it is now thirty years since the public have enjoyed the use of passenger vessels impelled by fire and steam, and that during this period not less than *thirty millions of persons* have been transported from time to time, in the various steam boats which have run to and from the city of New York, and that these steam boats have probably navigated a distance equal to *fifteen millions of miles*, and that in all this prolonged and varied exposure, *never, but once, has a single life been lost by the burning of a steam boat.* This fact alone, to the unprejudiced, speaks volumes in favour of the general care and skill of the parties, who have been concerned in this species of navigation."

To expose the absurdity of the protection law, and to give a fair idea of what it may be expected to produce here, we give the following table of known accidents and disasters to American steam-boats since the law of 1838, which was to have been such a palladium to the old women.

1838			
Oct. 27th	Cynthia,	Detroit River,	Burnt; passengers and crew saved by running on shore.
Nov. 25	Gen. Brown,	Mississippi,	Explosion, thirty lives lost.
1839			
January	Clarendon,	Sav. & Darien,	Burnt; crew and passengers saved.
,,	Ploughboy,	Mobile,	Sunk, on arriving at Mobile.
,,	Somerville,	Mississippi,	Sunk.
February	Oswego,	Ohio,	Sunk, near the mouth of the Kentucky.
,,	Alert,	Mississippi,	Eruption of steam; 4 scalded.
,,	Alice,	Pearl river,	Sunk.
March	Reporter,	Ohio,	Eruption of steam; 1 scalded.
,,	New York,	New Haven,	Burnt.
May	Avalanche,	Ohio,	Eruption or collapse; 5 killed.
,,	Rhine,	Missouri,	Explosion.
,,	Pilot,	Mississippi,	Explosion or collapse.
,,	Ponchartrain,	New Orleans for Tampico,	Explosion.
,,	Geo. Collier,	Mississippi,	Eruption of steam; forty-five killed or scalded.
,,	Erie,	Hudson river,	Collapse, 1 slightly wounded.
,,	Bee,	Arkansas,	Sunk.
,,	Indian,	,,	Sunk.
,,	Buckeye,	Mississippi,	Explosion; several killed or wounded.
June	Empire,	Oh o,	Sunk.
,,	Massillon,	,,	Collision and eruption of steam.
,,	Tennessee,	Cumberland river.	Burnt and sunk; passengers saved.
Nov.	Wilmington,	Mississippi,	Explosion; nineteen killed or wounded.
1840	Gallatin,	Cumberland river,	Collapse; three scalded.
,	Lexington,	Long Island Sound,	Burnt; about 124 lives lost.

"It may be seen that the most numerous and fatal of the accidents by steam have happened soon after the semi-annual inspections of the first of April and October. This fact will not appear surprising to practical men; who fully understand that the care and skill of official inspectors, cannot be advantageously substituted for the uncontrolled vigilance and practical knowledge and skill, of those who are in the constant care and superintendence of the boats and engines; and to whom a good reputation, the desire of safety and the love of life, afford stronger and more efficient motives to correct action, than can ever be furnished by the requirements or penalties of special enactments of the legislative power.

"The Cincinnati Gazette is stated to have published a list of steam boat disasters on the western waters during the last year. The sum total of losses is 40; of this number, 32 were an entire loss; snagged, 21; struck rocks, or other obstacles, 7; burnt, 5; burst their boilers, 4; run into other boats, 3—40. There were snagged on the lower Mississippi, 11; on the Missouri, 4; on the Ohio, 4; on the Yazoo, 1; on the Red River, 1. It is remarkable that a majority of the boats were snagged on their downward trips. Lives lost, by bursting boilers, 39; by other causes, 6. Total, 45. The amount of property destroyed in boats and their cargoes, is supposed to be not less than a million of dollars.

"On events like these, the provisions of statutory law can have but little influence; except as they may operate to deter the men of means, foresight and mental ability, from a business already too hazardous to their private interests, and which, most unwisely, has been made subject to the proscriptive action of the popular press, and of the national legislature."

Another extract gives a more powerful lesson.

"That the safety of steam boilers from explosions, does not necessarily depend upon working with so low a pressure as five or seven pounds to the square inch, and that a reasonable increase in the proportionate strength of the boilers in steam vessels would remove all immediate hazard, and nearly end the catalogue of these disasters, is rendered apparent by the facts which relate to this branch of navigation, as it has been carried on in various directions from the city and port of New York. Here, where steam navigation was first successfully established, and where it has probably attained its highest degree of efficiency, we might have expected that accidents and disasters would, not unfrequently, attend the use of a power at once so novel and energetic. The accidents and fatalities which have here occurred, as well as their probable proportion to the pressure of steam, the number of boats employed or trips made, the number of miles navigated, and the number of passengers which from time to time have been exposed, are set forth in a table.

"The table, so far as relates to the service performed on the different routes and the number of persons exposed, is made up approximately, by estimates founded on my general acquaintance with our steam navigation; but is believed to be sufficiently correct for general purposes. I have separated the business of the fifteen years which it comprises, into three several periods of five years each, commencing with 1824; early in which year the navigation, in this state, which had previously been controlled by the associates of Fulton and Livingston, was thrown open to all competitors.

"It appears from the average results of the table, that during even the first period of five years after the navigatioa was thrown open to public competition, the ratio of steam accidents was only equal to one, for more than 20,000 trips or passages; and that the average loss of life was only equal to one, for more than 126,000 passengers exposed. Thus, at the fair outset of this noble enterprise, a degree of safety was attained for the passenger, such as may well challenge comparison with any artificial means of transit or locomotion that have ever been resorted to by the human race.

"It appears further, on comparing the results for these several periods, that the ratio of steam accidents for the first and third periods, as compared with the probable number of trips made, has decreased from one in 20,317, for the first period, to one in 317,105, for the third or latest period; showing a diminution of the ratio of accidents in the average period of ten years equal to *about* 84 *per cent.* The ratio of lives lost from these accidents during the same period, has also decreased from one in 126,211, to one in 1,985,787; equal also to a diminution in the ratio of personal hazard, in this short period, *of* 84 *per cent.*

"It appears also from the table, that during the first of these periods the average number of miles navigated by all our steam boats, to each explosion which occurred, was equal to 235,646: a distance equal to many times the circumference of our globe, and about equal to that from the earth to the moon. But even this ratio has been rendered tenfold more favourable in the short average period of ten years, being for the latest five years, 2,733,725 miles navigated for each explosion; or more than eleven times the distance from the earth to the moon; and reducing the ratio of hazards in proportion to distance, *almost* 90 *per cent.*

"This remarkable diminution of accidents and hazard, it may be seen, has taken place in the very period in which the average working pressure of steam has been more than doubled. It has also been attained solely by professional skill and experience, and without any aid from legislative interference; for the law of Congress on this subject was not in force till near the close of the year 1838. Had such a system of legislation been at first adopted, there are sound reasons for concluding that it would not have prevented disasters, but might have greatly retarded the rapid advance in safety, as well as improvement, which has been so happily attained."

It is thus seen that with an increase of pressure a decrease has taken place in the number of casualties. In the first period the estimated average pressure was 7 lbs.; in the second period 14 lbs.; and in the last period 18 lbs.

We cannot conclude this better than by laying before our readers the eloquent vindication of Western steam navigation, which was given before Congress by the Hon. Mr. Rumsey, of Kentucky.

"Sir, you have no arithmetic of powers vast enough, by which to estimate the benefits of the steam boat in a pecuniary point of view alone. Its labours, too, have tended, in no small degree, *to the preservation of human life*. I am aware that the truth of the last assertion may not be universally admitted; but it will scarcely be questioned, at least by a western or south-western man, who recollects the old mode of conducting our commerce. Small as the commerce was before the introduction of the steam boat, it drew off a larger portion of the population than is now necessary to transact it, although so immensely extended. Even then, more died in the long, and exposed, and laborious voyages in keels and barges, or the exhausting return by land, under a vertical sun, than now perish by steam boat explosions. But they dropped off one by one; they sank obscurely into the grave by the way-side; or, after reaching their homes, fell victims to disease incurred by a sojourn and travel in southern climes. The consumption of life, though known to be great in the aggregate, happening so much in detail, made no public impression. But now, every steam boat accident creates a sensation, and is proclaimed in the universal press of the country. If the mighty commerce now in progress on the western waters, had to be conducted in the old way, it would require the agency of so many individuals, that it would not be long before the sides of the public roads from New Orleans to the Upper States, and the banks of the great river which pours into the gulf the congregated waters of nearly half a continent, would be almost continued grave-yards."

NOTES OF THE MONTH.

This month has been more fertile in deaths than in any thing else. In this number is Thomas Drummond, Lieutenant in the Royal Engineers, F.R.S., Under Secretary of State for Ireland, &c. His labours in the Ordnance Survey of Ireland, and his discovery of the hydro-oxygen light, which bears his name, are well known to the public. As an Irish Railway Commissioner it was our lot to oppose him, but we are free to confess that it was to Drummond that the report was indebted for its most valuable portions. He died on the 18th ult., at Dublin, and was honoured with a public funeral, which he highly merited.

Pitts, the sculptor, unfortunately committed suicide on the 16th ult., in his 50th year. He was an artist of high merit, who it is to be hoped will receive that honour now which he pined for in his lifetime. Among his works are the Shield of Eneas, from Virgil, and that of Hercules, from Hesiod, compositions and designs from Virgil and Ossian, intended to be published in the same form as Flaxman's from Homer, the Nuptials of Perithous, the Apotheosis of the English poets, and several other reliefs which adorn Buckingham Palace. The Brunswick Shield was another of his works.—The Chevalier Gasse is also dead. He was architect to the King of Naples, Corresponding Member of the French Institute, and of the Institute of British Architects.

The Easter holidays have given some check to business, so that we have little to record. Spencer's Electrotype is now receiving the attention which it deserves; some months ago it was smothered under the blaze of photography. Seals and copies of medals are made by this means with great accuracy and celerity.—Jacobi's galvanic engraving is also acquiring publicity. We may mention by the bye that as his other electric inventions have not exceeded those of our countrymen, so his application of electro magnetism as a motive power is derived from an Englishman.—Smee's battery described in our present number will give fresh power to the professors of this important branch of science.—Claudet and Houghton's specimens of Daguerre's process of photography now exhibiting in Holborn, are well worthy of inspection, they give good earnest of the aid this admirable invention will afford to the arts. Its application to the delineation of architectural and antiquarian subjects will make it of great value to the profession. The Elgin marbles should be copied by this method.

The vacuum engine is the wonder next to be exhibited; a new application of agriculture, by which it is said, above twenty square miles can be cultivated by one stationary engine has been patented, and will be shown to the public on a small scale early in the ensuing month.—It will be recollected that Hague's draining apparatus is on this plan, and a steam engine erected by Mr. Hague at Constantinople, works a powder mill seven miles off, at a place where the Grand Signor refused to allow any steam engine to be erected within that distance.—Mr. Maugham, the lecturer on chemistry, has removed from the Adelaide Gallery to the Poletechnic. At this latter Institution an ingenious application of propellers to the balloon is shown, although their success on a large scale is doubtful, from their incapacity to contend with currents of air.

The plan for embankment of the Thames is now before the legislature, so that we may expect something as a beginning.—The wood pavement companies are getting on faster than the asphalte, they are at work at Buckingham Palace, in the Strand, Oxford Street, St. Giles's, and Lamb's Conduit Street The elasticity of this material forms one of its best properties. Under most of these pavements a firm bed of concrete mixed with Roman cement and puzzolano is laid, rather expensive we should think.

The Marine Gallery at Hampton Court Palace was opened on Easter Monday, so that the maritime nation has at last two marine galleries.—The Government School of Design at Somerset House has made another step out of the humdrum system; having obtained a set of casts from Messrs. Lofts in Dean-street. How they could persevere in their exclusion of the figure, it is difficult to conceive; they have only to go into their own schools and look at the drawings of the same ornaments affixed to the walls; those from casts are full of life and spirit, and in high relief, those from engravings more laboured are dead and flat. In fact the wisest thing they could do would be to turn every engraving out of the school, where they can substitute nature or casts, and above all never to let a boy begin to draw from a drawing,—set him before the Apollo or the Venus at once. This has been tried at the Leicester-square school with full success, even on its very young boys. The latter is far before Somerset House in principle; thanks to their badly remunerated Director Mr. De Mouchet. The modelling class at Leicester-square gets on well. We hope the inspection of Mr. Wyse at Somerset House last month will do some good; that patron of the arts has, it is said, suggested many modifications in the establishment. One fruit of his visit is a report from the council, the first since their institution. Pretty fair from a national establishment! It is a pity these establishments are not more frequented, where the working classes can obtain first rate instruction in the arts for *sixpence a week*. The whole number of students at the school is not more than two hundred.

Pneumatic Experiment on the Birmingham, Bristol, and Thames Junction Railway.—The engine-house is built, and the communicating tube between it and the railway, by which the exhaustion of the main tube is to be effected, is nearly laid. The permanent way and rails are also almost completed, and fit for the laying down of the tubes for a considerable distance out of the 1¼ miles on which the experiment is to be made. We perceive also that a great many of these tubes are already arrived and on the ground. They are nine inches diameter, and are lined inside, to about the tenth of an inch thick, with a hard unctuous substance, much resembling, in its disagreeable and suffocating smell, hard tallow. The slit or aperture of the tubes through which the arm communicates with the running piston and the carriages is about 1⅜ inch. We understand, if the experiment be successful, the company are to have the use of the patent gratis, for devoting the road to the trial, and are to purchase the whole apparatus and preparations at cost price; and if it does not succeed, all is to be cleared off within a given time. Supposing the experiment effects all that its advocates expect, we cannot see the use of so small an apparatus in such a place. If we remember right, the inclination of the road, about that part, is 120 feet a mile; therefore, the traction is more than three times that on a level, or above 24 lbs. to the ton. But a circular tube 9 inches diameter, fully exhausted, and exclusive of all friction, would only draw about 954 lbs., or, at 24 lbs. per ton, under 40 tons. The probability, however, is, that it will never in that length be half exhausted; so that the absolute load it would take would be under 20 tons, carriages, load and all, assuming a perfect absence of all friction in the machinery. We shall, however, be much surprised, if the useful effect is anything like this. Our opinion is, that the patentees have made the apparatus much too small for any useful purpose upon such a road, and also for the purpose of showing off the invention well, assuming it to be all that can be expected of it. A few days ago the works were suspended, in consequence of a dispute between the Messrs. Samuda and the contractors, about the point of delivery of the tubes —that is, whether it should be a few yards on the north, or a few on the south of the crossing of the Great Western line. Where so much is involved as here, this dispute is equally as ridiculous as that of the Lilliputians and their neighbours, about which end eggs ought to be broken.—*Railway Magazine*.

Galvanic Engraving.—It is not generally known that the method of producing fac-similies of engraved plates by means of voltaic electricity, as indicated by Mr. Brande, Mr. Faraday, and Professor Jacobi, has been frequently demonstrated with complete success by Bachhoffner, of the Polytecnic Institution, in Regent-street, at which establishment many satisfactory specimens may be witnessed. The process is as follows:—The plate from which the duplicate is to be taken is first placed in a vessel properly adapted for the purpose, and is then covered with a solution of sulphate of copper, through which the galvanic stream is transmitted. This causes a decomposition, or, in other words, the constituents of the salt are removed from each other, the metallic copper resulting from the action being deposited in a series of thin laminæ upon the original plate. This deposited copper forms a second plate, which, on removal from the other, exhibits every line and mark traced by the graver or etching-tool upon it, with this difference, that what is bas-relief in one is alto-relief in the other, and the engraved lines of the original are raised lines in the duplicate. The sheet of copper thus produced becomes a normal plate or mould; from which, by a similar process, an *ad infinitum* number of plates may be taken, in every respect equal to the original, and capable, like it, of giving perfect printed impressions. The value of this practical discovery is great, inasmuch as it will supersede the necessity of expensive steel-plate engravings, by multiplying copies of those on copper plates at the cost of a few shillings and loss of a few days only. Impressions from medals, coins, and dies may be obtained in the same way, of which there are several specimens in the gallery of the Polytecnic Institution, as well as a very large duplicate copper plate of an elaborate engraving from one of Domenichino's pictures.

ON BLASTING LIMESTONE ROCK.

Some Account of Blasting the White Limestone in the County of Antrim, in Ireland. By WILLIAM BALD, F.R.S.E., M.R.I.A., &c. *Read before the Institution of Civil Engineers.*

IT becomes necessary to make a few short observations which may perhaps be interesting to the scientific engineer. Along the north coast of Ireland from the Bay of Belfast to Lough Foyle, the country consists of white limestone: columnar basalt, and some conglomerate sandstone; but the hill of Carey consists of mica slate; and is of the same formation as the Mull of Cantire, a part of the coast of Scotland lying opposite. The geologist can here easily trace the connecting link in the formation, which joins the two countries, although a channel 90 fathoms deep separates them. Numerous whin dykes intersect the strata along this part of the Irish shore, they run nearly parallel to each other in some cases, and are very remarkable in their structure.

The study of the peculiar qualities of the respective rocks and strata, and their position and inclination, will enable the engineer to work them in a more scientific manner. And in the construction of harbours, lighthouses, lines of navigation, drainage, roads, &c. &c., an intimate acquaintance with the component parts of the rocks will enable him to select those best suited to resist the action of time, whether they be placed under the dominion of the deep, exposed to the ravages of the pholas, or subject to perhaps the more wasting influence of the atmosphere; by such studies his skill will be alike visible in the selection of the best material for the repaving of even a common road, as it will be for that of the most splendid edifice destined to survive ages.

In constructing the Antrim coast road it became necessary to cut through extensive and high masses of white limestone; one of the sea cliffs in the Little Deer Park, near Glenarm Town, extended to a length of nearly one thousand yards, rising from twenty feet to about two hundred in height, washed at its base by a deep sea, and entirely exposed to the run of the ocean in the north channel.

Above the white limestone is situate the columnar basalt, but no part of the road was cut through this last mentioned rock. The white limestone in Antrim differs from the chalk in England, in being more indurated, while in other respects it is similar to it in the quantities of flint it contains. This rock is close and fine in its texture, but it is deeply fissured in many directions; the scull veins it exhibits are extremely curious.* The inclinations of the limestone strata on this part of the coast does not in general exceed 15° dipping into the land. Under the lime rock strata lies the brownish red coloured sandstone.

In blasting down those lofty cliffs of white limestone, the borings were always made into the toe of the rocks, and were so arranged that the line of least resistance should not be in the direction of the line of boring. Hundreds of tons of rock frequently rested on a base of a few superficial feet, which being blasted away, the cliff above tumbled down. The patent safety fuse was used, and which was attended with the most beneficial results, copper tubes for putting in the charges, and also copper needles.

During three years operations not a man was lost, although upwards of one hundred thousands tons of limestone were blasted down upon less than one mile of the road.

The following are the results of a few experiments made upon loose detached blocks of white limestone at Glenarm, Little Deer Park.

	Cubic feet in each block.	Quantity of powder used.	Cubic feet for each ounce of powder used.
Block No. 1.	165	12 oz.	13·78 ft.
2.	180	12 oz.	15·00
3.	540	38 oz.	14·21
4.	864	64 oz.	13·50

From the above experiments it took one ounce of gunpowder to rend asunder 14·12 cubic feet of the white limestone when in blocks. And from experiments made on the solid loose whinstone blocks, it took about one ounce of gunpowder to blast asunder 11·75 cubic feet.

Three experiments assigned the specific gravity of the white limestone at 2,747, 2,769, 2,763; and the whinstone or basalt at 3,200, being about 13 cubic feet of white limestone to the ton, and 11·20 cubic feet of the whinstone to the ton.

* The grey limestone with which the Light-house of Clare Island is built is much traversed by scull veins, and water enters them during severe rain storms.

TABLE OF THE WORKING PROCEEDINGS.

	Depth of boring.	Quantity of powder.
An auger of 1¼ inch diameter.	15 inches deep.	6 inches.
Ditto 1½ ditto	26 ditto	8 ditto.
Ditto 1¾ ditto	30 ditto	9 ditto.
Ditto 1¾ ditto	36 ditto	12 ditto.
Ditto 1¾ ditto	48 ditto	17 ditto.
Ditto 2 ditto	5 feet	20 ditto.
Ditto 2 ditto	6 feet	27 ditto.

The above table exhibits the diameter of the auger or jumper used, the depth sunk, and the number of inches of gunpowder* put in.

The force of the explosion of gunpowder is assumed to be as the cube of the length of the line of least resistance, thus if one ounce of gunpowder will open a distance of one foot of rock, the table would run thus:—

Line of least resistance.	Charge of powder exclusive of priming.
If 1 foot of rock requires	1 ounce.
2 feet would require	8 ditto.
3	27 ditto.
4	64 ditto.
5	125 ditto.
6	216 ditto.
7	343 ditto.
8	512 ditto.
9	729 ditto.
10	1000 ditto.

I am aware there is much difficulty in knowing exactly where the line of least resistance is, because the rock may be fissured, or some bed or opening may be near to the line bored, and this is the case where the rocks are stratified; but the hypogene rocks, such as granite and syenite, lying in large solid compact masses unstratified will be different, and these rules may be usefully applied. In blasting asunder loose detached blocks, a much greater quantity of material will be blown asunder by the same quantity of gunpowder than of rock lying in close connected beds.

It is always desirable to work the rock out by the dip of the inclination of the strata, or as the quarrymen call it, the going way of the rock.

In the white limestone quarries lying in the high ground north of the town of Belfast, where the limestone is quarried for building and agricultural purposes, and also for export; two men will quarry out at an average from eight to ten tons per day, the augurs or jumpers generally used are 1⅝ inches, and two inches diameter; and the induration of the white limestone may be estimated when two men will bore one foot deep in half an hour; they generally put in about three inches of powder for 15 inches deep, and 6 inches for about 2 feet deep; the expense for quarrying is about from fivepence to sixpence per ton. There are nearly 13 cubic foot of the white limestone to the ton, which is at the rate of nearly about one shilling per cubic yard. This white limestone is much esteemed in Glasgow and all the towns on the Clyde, where it sells for five shillings per ton—but the quarrying works near Belfast are carried on in a very limited manner, or rather on a very small scale.

Numerous experiments made by military engineers assign the force of the explosion of gunpowder to be as the cube of the length of the line of least resistance. Vauban and Belidor,† both of them excellent mathematicians, and also possessing great practical skill, ingenuity and experience, investigated this subject, doubtless more particularly with a view to the operations of war, than to those of the works of the civil engineer. The law of the explosive force of gunpowder remains the same in all the various forms it may be applied to matter, whether in blasting out of rock or earth, or the destruction of the masonry of fortifications by blowing them up, or laying in ruin bridges built over large and deep rivers to arrest the progress of hostile armies.

The total cubical contents of the four blocks of limestone given above, amounted to 1749 cubic feet, and the quantity of powder used 126 ounces, being at the rate of 1·94 ounces for each cubic yard blasted asunder. But if the rate per cubic yard be deduced from the quan-

* One pound of gunpowder occupies 30 cubic inches.

† Belidor, one of the most scientific of the French engineers, has given the following rule for finding the charge of a surcharged mine or globe of compression, "is to multiply the length of the line of least resistance in feet by 00, and the product will be the weight of the powder in pounds."

tity of powder expended on each block, then the following will be the results obtained from the four experiments.

165 cubic feet was blasted asunder by 12 ounces of gunpowder, which is at the rate of 1·95 ounces of powder for each cubic yard.

180 cubic feet was blasted asunder by 12 ounces of gunpowder, which is at the rate of 1·80 ounces of powder for each cubic yard.

540 cubic feet was blasted asunder by 38 ounces of gunpowder, which is at the rate of 1·90 ounces of powder for each cubic yard.

864 cubic feet was blasted asunder by 64 ounces of gunpowder, which is at the rate of 2 ounces of powder for each cubic yard.

Therefore in the large loose limestone blocks about 2 ounces of gunpowder may be taken as the expenditure being necessary to blast out each cubic yard. The four blocks on which these experiments were made, were not at all cubical, although the one which contained 540 cubic feet was nearly so. From the above results i beg to submit some calculations regarding the force of the explosion of gunpowder, being as the cube of the length of the line of least resistance.

We are in possession of the quantity of gunpowder used in blasting the four blocks, and also of the solid feet contained in each of them. Extracting therefore the cubic root of the cubical contents of each block, we shall then have their masses all in cubical form as follows:

Cubic feet in each block.			Side of the cube.
$\sqrt[3]{165}$	-	-	5·484
$\sqrt[3]{180}$	-	-	5·646
$\sqrt[3]{540}$	-	-	8·143
$\sqrt[3]{861}$	-	-	9·524

Taking the length of the line of least resistance at each of these cubes to be equal to the distance from the centre to the nearest point on the surface, or equal to half the side of the cube, then the following will be the lengths in feet of the lines of least resistance.

In cube No. 1 — 2·742 feet.
No. 2 — 2·823
No. 3 — 4·071
No. 4 — 4·762.

The quantities of gunpowder consumed to blast asunder a line of least resistance, of

2·742 feet was	12 ounces,	165	cubic feet blasted asunder.
2·823	-	12 ditto,	180	ditto.
4·071	-	38 ditto,	540	ditto.
4·762	-	64 ditto,	861	ditto.

If 165 cubic feet be blasted asunder by 12 ounces of gunpowder, the line of least resistance in that mass, if in cubical form, will be

$$\sqrt[3]{165} = 2·742 \text{ feet.}$$

Then the line of least resistance for one foot in cubical form will be equal to 8 cubic feet. Then if 165 cubic feet with a line of resistance of 2·742 feet require 12 ounces of gunpowder to open it, then 8 cubic feet with a line of resistance of one foot will require 0·582 ounces of gunpowder to open it asunder.

The following are the quantities of gunpowder required to open one foot of least resistance through the white limestone, as determined by the blasting of the four blocks.

Cubic feet in each block - - -	165	180	540	864
Quantity of powder used to rend it asunder, in *ounces* - - - - -	12	12	38	64
Cubic feet opened by the line of resistance of one foot - - - - - -	8	8	8	8
Quantity of powder required to open the line of least resistance of one foot, in *ounces* - - - - - -	0·582	0·533	0·563	0·593

Mean 0·568 oz.

Apply the rule of the cube of the length of the line of least resistance, and working with the element just obtained from the four experiments, to open asunder the line of least resistance of one foot.

No. 1—Then the scale of the length of the line of least resistance in No. 1, $2·742^3$ feet multiplied by 0·582 ounces, the quantity of powder to open one foot will be $2·742^3 = 20·62 \times ·582 = 12$ ounces.

No. 2—For a line of least resistance of 2·823 feet will be 11·95 ounces, $2·823^3 = 22·42 \times ·533 = 11·95$ ounces.

No. 3—For a line of least resistance of 4·071 feet, will be 37·97 ounces, $4·071^3 = 67·45 \times ·563 = 37·97$ ounces.

No. 4—For a line of least resistance of 4·762 feet, will be 64 ounces, $4·762^3 = 107·983 \times ·593 = 64$ ounces.

It is therefore clear from these experiments made that the force of the explosion of gunpowder is as the cube of the length of the line of least resistance. Taking the mean quantity of gunpowder obtained from the four experiments to open asunder a line of resistance of one foot, and which is 0·568 ounces. The following will be the results calculated according to the cube of the length of the line of least resistance.

$$2·742^3 = 20·62 \times 0·568 = 11·71 \text{ oz.} = 165 \text{ cubic feet.}$$
$$2·823^3 = 22·42 \times 0·568 = 12·73 \text{ oz.} = 180$$
$$4·071^3 = 67·45 \times 0·568 = 38·31 \text{ oz.} = 540$$
$$4·762^3 = 107·983 \times 0·568 = 61·33 \text{ oz.} = 864.$$

In having described the mode of blasting the white limestone on the Antrim coast road in the north of Ireland. It may be useful as well as interesting to the engineer to describe its qualities, and to what extent it may be employed in the construction of works.

In treating of the nature of any kind of material to be employed in building, the first consideration is its character, to resist decomposition whether placed in the open air exposed to the full action of the atmosphere, or buried in the earth, or entombed in the deep. Its induration and compactness of structure, the absence of figures, the mass it can be had in, and the facility of working or tooling it into form.

The white limestone on the Antrim coast road lies in beds dipping slightly to the plane; it is generally quite white, but sometimes it is of a yellowish tint; it is traversed by very small veins of calcareous spar, but the most remarkable feature is the quantity of flints it contains, they are dry, grey and black; the thickness of the beds of the white limestone is very singular, being sometimes more than 30 feet.

This white limestone is not good for building, because it moulders by exposure to the atmosphere, it is not therefore generally used in any public building, although it might be used in filling up the interior parts of walls: it is inferior for road metal, being tender and wearing quickly; it can be procured in large masses, when reduced to pieces containing six, twelve and eighteen cubical inches, it breaks into irregular fragments with sharp edges.

The white limestone when placed under the sea is particularly subject to the ravages of the pholas, and is therefore unsuitable to be employed in the construction of marine works, such as harbours or breakwaters, &c., it is however a valuable material for making lime for building, and for agricultural purposes. In our quarrying operations we rarely found in it shell remains.

In quarrying it out in large masses, the blocks sometimes had what the workman call a lean and a full bed; the lean bed being less than an angle of 90°, and the full bed more than 90°. The white limestone can be split with plug and feather, or pooled by wedges; if the stratification be in thin beds, it opens across with a very rugged and irregular face, but if very solid and compact, and the beds of great thickness, it will open more evenly and equal in the face. It dresses readily with the hammer, and can be wrought and hewn into any form. I am however of opinion that the white limestone of the county of Antrim should not be used in constructing any work requiring durability, because it is a rock liable to decomposition when exposed to the atmosphere.

I have already, in the paper on blasting the white limestone, alluded to the small fissures which traverse that rock, and which also traverse the blue and grey limestone of Ireland, and which the stone-cutters call scull veins doublers, on account of their exact resemblance to the sutures in the human scull.

In concluding, I beg to mention that there are several species of the Pholas. Lamarh in his natural history, mentions the Pholade Dactyle or Pholas Dactylus, as being very prevalent on the coast of France, and also inhabiting the shores of the British seas. I have given a sketch of the Phoylas Dactylus, and I beg to present to the Institution a very beautiful specimen of this kind, from which the sketch has been made, and which specimen I have accidentally obtained in London. There is another species called the Pholade Serabrelle, or Pholas Candida, which inhabits the European seas, and a very small kind called by the French Saxicave Ridée, Saxicava Rugosa. It is quite foreign to the object of this paper to enter into any thing like giving an account of all the various kinds of Pholas, or their habits; it is quite sufficient to the engineer to know that every description of calcareous rock, when placed under the sea, is subject to be perforated by those bivalves; indeed every rock upon which acids act are subject to be destroyed by them, and it consequently has been conjectured that they possess the power of producing an acid that decomposes the rock containing calcareous matter; on the other hand some maintain this is not the case, because the acid would also decompose the shell which covers them. Mr. Lonsdale, of the Geological Society, mentioned to me that some marine works constructed at Plymouth were much injured by the ravages of the Pholas. Beds of calcareous rock of several feet in thickness, in the Frith of Forth have been entirely destroyed by the Pholas.

It will be seen that the shell of the Pholas Dactylus, presented to the Institution, is very tender and delicate; from the extreme fragile nature of the shell it would not be supposed capable of destroying indurated marble. The external surface of the shell is rough, and radiated transversely and longitudinally in a most beautiful manner by curved lines of a high order; an attentive study of the mere lined surface of the shell cannot fail to be instructive even to the man of science, and worthy to be contemplated and examined by all those engaged in the works of art and taste. The marine engineer may derive instruction from the parabolic curves delineated, and traced out by the hand of nature on the Pholas shell, in assisting him in giving the best shape to the slopes of breakwaters, and harbours constructed in the deep sea, and exposed to the run or momentum of the ocean. The curved radiation or fluting on the shell cannot fail to attract the architect engaged in the works of design and taste. It ought not to be forgotten what struck Watt in examining the joints in the tail of a lobster; nor of Smeaton in looking at the form of an oak tree; nor the falling of an apple which gave the impulse to the genius of a man justly the glory of our island, and whose name stands recorded with the proudest triumphs in the loftiest branches of science that has yet adorned the efforts of human ingenuity.

William Bald.

ENCROACHMENTS OF THE SEA AND FORMATION OF SHORES.

Sir—Public attention has of late years been much engaged by the phenomena observed upon the ocean. The tidal theory, currents, storms, &c. have each been subject to the closest scrutiny, and the result has been much valuable information connected with them. The recovery of land, and the encroachment of the sea, have been for some time, and are now subjects of great interest to the scientific world; this has induced me to request the insertion of the following few lines in the columns of your valuable journal.

The northern shore of the Bristol Channel from the port of Cardiff up to Gloucester consists of a vast flat of Moor land, varying from 1 to 1½ miles in breadth; the soil is composed of a very tenacious clay mixed with shells and a large portion of decayed vegetable matter. This tract is formed totally from the deposit of the waters of the Severn and Bristol Channel. This fact is inferred from the following circumstances:—1st. The soil above described commences about a mile and a half inwards, where its section presents a depth of about a foot, under which is found the natural soil of the country, a yellowish clay intermixed with gravel; from this point it gradually deepens to high water mark, where the depth averages from 35 to 40 feet. 2nd. If a plate or any other body, having a flat surface, be exposed on the shore, between high and low water mark, for a single tide, a deposit will be found thereon varying in thickness according to the calmness of the sea during tide, as it has been observed that the deposit is much increased in stormy wheather when the sea is violently agitated. 3rd. In excavating the Bute Docks the rudder of a ship was found about 10 feet below the surface, the iron work of which was in excellent preservation. It was at first supposed that it had sunk down by its own weight, but its peculiar shape, and the closeness and tenacity of the soil, at once indicate the fallacy of such an opinion; several oak trees were also found about 30 feet below the surface, and about 100 yards above high water mark, these were of sufficient hardness to admit of their being worked up into chairs, boxes, &c.

Fig. 1. Fig. 2

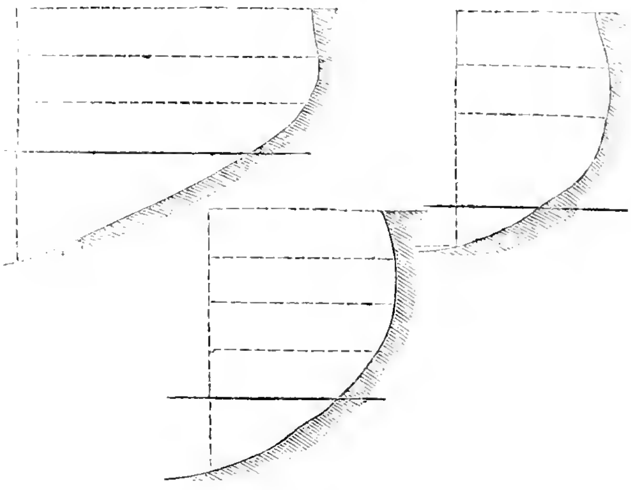


Fig. 3.

Fig. 1, the length of the upper ordinate is 6 feet, the second 6 feet 3 inches, the third 6 feet, the fourth 5 feet 1 inch, and the height of the vertical line 5 feet 9 inches. Fig 2, length of the upper ordinate 2 feet 11 inches, the second 3 feet 3 inches, the third 3 feet 2 inches, and the length of the vertical line 5 feet. Fig. 3, length of the upper ordinate is 3 feet 8 inches, the second 3 feet 9 inches, the third 4 feet, the fourth 3 feet 7 inches, and the length of the vertical line 5 feet 5 inches. The lower line is the height of high water and spring tides.

These facts, I presume, fully warrant my assertion that the shore is a deposit, and if so, it only remains to discover the cause, which appears to me to be as follows:—In many seasons when the Severn is swollen into a most impetuous and rapid torrent, vast quantities of the rich soils of Hereford, Gloucester and Worcestershire are washed down by it, and the particles prevented from sinking by the rapidity of the current, they are thus carried along until the stream is impeded in its progress by meeting the flowing tide, which runs in this channel with a velocity of from 5 to 6 miles an hour; the tide being the more powerful of the two currents, and having a set towards the south-east, pushes the other current over towards the nothern shore, where the water almost stagnates and the particles settle to the bottom. I am borne out in this opinion by the fact that there is but little current in the space between high and low water mark, a distance of about a mile, and which always sets to the westward whether the tide be ebbing or flowing.

At the high water mark the shore suddenly drops about six feet perpendicularly, the profile of the land at this part is exceedingly curious, and accompanying this paper I have sent a few sections taken at the more prominent parts, and consequently most exposed to the force of the wave. I think some very valuable hints might be taken from them in the construction of piers, sea walls, and other works exposed to the action of the sea. These sections were taken with much care, and may be fully relied on for accuracy.

I remain your most obedient servant,

NOTA.

ENCROACHMENTS AND RECESSIONS OF THE SEA.

[The following article is from the *Cinque Ports Chronicle* of February last, it is a reply to a paper which appeared in the Journal, page 64, for February last, under the signature E.]

We regret that "E," while he questions the accuracy of our theory, has not started some tangible objection for us to grapple with, and as he has not done this, we must content ourselves with a reference to some additional facts in corroboration of the view we hold of the subject. We find that as the projections of the Hastings cliffs are diminished, additional deposits of beach are formed in the West bay, gradually augmenting also at Dungeness Point, the extremity of the curve described by the sea, on account of the land, though low, consisting, we believe, of chalk or other formation, calculated to resist the action of the waves. It is also a fact that, as the Ness point augments to seaward by deposits of beach, the sea has recently made considerable encroachments to the eastward, or side opposed to the prevailing current. Within the last few days also, a temporary headland has been caused about one mile s.w. of Dover, by the fall of an immense quantity of chalk, denominated Round-down Cliff. Now by obstructing the parallel course of the western current, it would, according to our theory, throw the tide in with additional momentum upon the western pier of Dover harbour, and this, we believe, has since been realized, and so effectually as to diminish the bar of beach, which, for some months previously to this accident, had been collecting in serious and unusual quantities. Nature has thus, we conceive, by one of her accidents, demonstrated the means, which our celebrated engineers have hitherto searched for in vain, of preventing the formation of a bar of beach at the mouth of Dover harbour. Viewing that locality in connexion with our theory, we have no doubt that if masses of rock, forming a durable obstruction in the nature of a headland, were deposited at a proper distance from the entrance of the harbour, the artificial promontory would give such a curvilinear and additional impetus to the waves and current, as would tend to pass the beach beyond the east pier of the harbour.

The recent south-westerly gales have, however, contributed events under our immediate observation which, in our humble opinion, have triumphantly established the theory we have broached, and which "E" has not attacked on any specific point. The circumstances to which we allude are the following: a groyne was constructed some few months ago on the beach a little to the westward of the villas between Verulam Place and Warriors' Square, for the purpose of protecting the esplanade wall to the eastward. That it effected by retaining the beach, which effectually repels the inroads of the waves. Here, then, we had a promontory formed on a miniature scale, and it was not long before what we conceive to be the great law of nature, viz., the formation of a bay exactly proportioned to the obstruction caused to the sea by an intervening headland, became too apparent. The waters, interrupted in their course by the beach collected at the groyne, were thrown with an additional impetus to the eastward of the groyne, exactly, we believe, proportioned to the obstruction they had encountered, and after repeated assaults upon the wall, have undermined, washed it, the parade, and part of the road away, clearing out a bay, which, from measurement, we find about the perpendicular length of the groyne, which was the passive cause of the inroad. Had the groyne in question not been erected, although the wall would have been undermined and thrown down by the groyne farther west, at the South Saxon hotel, yet the inroad would have been less considerable; or had the effects of our miniature promontory been diminished, by constructing it on a smaller scale, and neutralizing its *mischievous* tendency by a well graduated line of groynes to the eastward, the inroad would have been prevented. Groynes on this part of the coast are well known to have the effect of saving and protecting land to the westward, and of endangering it unless the groynes be continued to the eastward; this any common observer would satisfactorily demonstrate to "E," and in explaining the grand alterations in the face of the coast, by reference to such miniature causes, we believe, our views are unquestionably substantiated, as far as the encroachments of the sea are concerned; and we are equally confident in the accuracy of our views with respect to the recessions of the sea, that they occur in proportion as the headlands, which, under the agency of the prevailing current, formed bays, are diminished. This would, we believe, be experimentally proved if the groyne, which has caused the injury to the esplanade wall at St. Mary Magdalen's, were reduced in length and height. The sea would throw up beach where it has recently invaded, and there it would remain to an extent exactly proportioned to the diminution of the westerly groyne or headland. Similar reductions have taken place in groynes farther to the eastward, which had been constructed on too large a scale, and their destructive tendency to the eastward thereby reduced in a direct ratio. With these facts, supporting the theory we have advanced for the general cause of the encroachments and recessions of the sea, we must, until "E" succeeds in shaking our data, instead of merely questioning them, assume that we have offered a satisfactory explanation of the interesting phenomena afforded by the alteration of the Southern coast, and, in conclusion, express a conviction that if Beachy Head and the Hastings cliffs were severally extended to the distance seaward that now exists between Pevensey castle and the sea, and also between Winchelsea,* and the present high-water mark, such an elongation of the obstructing headlands would give such an additional impetus to the sea, as to cause it again to wash the base of the hills on which those towns are situated. We have affirmed that the perpendicular line, from the ordinary high-water mark to the furthest discernible inland existence of beach, is equal to the original projection of the headlands beyond their present termini, and we believe it to be correct. We, however, invite inquiry on the subject, as also to the cause of the *regular high-water marks* successively following each other for a considerable distance on Lydd beach; the early ones being covered with green sward, evidently the produce of ages.

RESISTANCE TO RAILWAY TRAINS.

Dr. Lardner recently delivered at the Athenæum, Manchester, a course of lectures "On the resistance of railway trains, the effects of gradients, and the general economy of steam power."

Lecture I.

Dr. Lardner commenced by observing, that it was a strong example of the manner in which practical matters were conducted in this country, that they had been now ten years, with all the extraordinary effects of railways passing under their notice, stimulating their attention and calling up the wonder of all parts of Europe, and yet to this hour the general problem, the solution of which was the actual amount of resistance to railway trains, might be considered to remain, so far as the engineering profession was concerned, without solution.

It was not till a very recent period that, even on common roads, the amount of this resistance had been made the subject of inquiry. An instrument had, however, been invented by Mr. M'Neil, the engineer, who had instituted experiments to ascertain the actual resistance on turnpike roads, which he had found to be about one thirtieth part of the load. Now, the principle was equally applicable to common roads as to railways, that the resistance would be diminished in the proportion in which they enlarged the wheel; but when they increased the size, they also increased the weight, so that there was a practical limit to the diminishing of resistance in this manner. The average resistance which a load placed on a railway offered to the tractive power, was intimately connected with the principle upon which railways themselves were constructed; and this connexion had been largely acted upon by the legislature in all inquiries concerning contested railway bills. It had been assumed in parliament that an engine might be expected to pull a load, with all the necessary expedition, up an inclined plane, provided that inclined plane offered not more than double the resistance which the engine had opposed to it on a level. That had been laid down and acted upon in parliament as a species of standing order. The principle acted upon was, that the resistance upon a level would be about 9 lbs. a ton, and, consequently, an inclination which resisted 1 in 250, was an inclination up which the engine might be expected to work with a full speed. Upon this principle the sections of all the railways in the country had been laid. But the fact was, that the resistance depended upon entirely different principles. In the inquiries which took place, no one ever hinted that the resistance depended upon the speed—no one suspected for a moment that there was more resistance at thirty miles an hour than at one mile an hour. He was quite sure that many would be perfectly astonished at this statement, but it was a fact established by abundant evidence, and innumerable experiments made by philosophers at different times and in different countries, that resistance depended upon friction, and did not depend upon speed; that so far as resistance to any degree depends upon the friction of the axles upon their bearings, or the rolling motion of the tires upon the road, it was demonstrable that the resistance was the same at all speeds whatever, whether twenty, thirty, forty, or fifty miles an hour. Never supposing there was any other cause, they at once assumed that resistance, at all speeds, was either actually or nearly the same. This was the source of the error.

One of the standing orders of parliament was, that whenever a railway had a curve, with a radius of less than a mile, the committee must make a special report of such a curve, upon the supposition that it was attended with increased resistance or danger. The popular idea was, that when the wheels got to the curve, the outer flange of the wheel mounted upon the rail, by the conical form of the tire, while the other fell from off the rail; thus the one wheel acquired a diameter virtually greater than the other; that, therefore, one revolution of the outer wheel, having a virtually greater diameter, would carry it over a greater space than one revolution of the inner wheel; and that the two things would accommodate each other so that the outer wheel gets round a larger portion of the rail, while the inner wheel, being virtually smaller, gets over a smaller space, and that in this way the cone of the wheel accomplished the thing. Never was there a more consummate mechanical blunder. The fact was, the cone had nothing to do with the traversing of the carriage round a curve; and it was entirely the mechanical action of the flange pressing on the rails.

He had alluded to one or two circumstances connected with the practicable and probable speed likely to be attained on railways, and the means by which that speed might be attained. Since the great questions which had been agitated respecting the effect which an increased width of rails would have on railway transit, and the effect which very large drawing wheels, of great diameter, would have on certain railways, the question of very vastly increased speed had acquired considerable interest. Very recently, two experiments had been made, attended with most surprising results. One was the case of the Monmouth express. A despatch was carried from Twyford to London on the Great Western Railway, a distance of thirty miles, in thirty-five minutes. This distance was traversed very favourably, and being subject to less of those casual interruptions to which a longer trip would be liable it was performed at the rate of six miles in seven minutes, or six sevenths of a mile in one minute, or 360-7ths of a mile (very nearly $51\frac{1}{2}$ miles) an hour. He had experimented on speed very largely on most of the railways of the country, and he had never personally witnessed that speed. The evaporating power of those engines was enormous. Another performance, which he had ascertained since he arrived in this neighbourhood, showed that great as the one was just mentioned, they must not ascribe it to any peculiar circumstance attending the large engines and wide gauge of the Great Western Railway. An express was despatched a short time since from Liverpool to Birmingham, and its speed was stated in the papers. One engine, with its tender, went from Liverpool, or rather from the top of the tunnel at Edge Hill, to Birmingham, in two hours and thirty-five minutes. But he had inquired into the circumstances of that trip, and it appeared that the time the engine was actually in motion, after deducting a variety of stoppages, was only one hour and fifty minutes in traversing ninety-seven miles. The feat on the Great Western was performed on a dead level, while, on the Grand Junction, the engine first encountered the Whiston incline, where the line rises 1 in 96 for a mile and a half; and after passing Crewe, it encountered a plane of three miles to the Madeley summit, rising 20 feet a mile, succeeded by another plane, for three miles more, rising 30 feet a mile: yet, with all these impediments, it performed the ninety-seven miles in one hour and fifty minutes, or 110 minutes; consequently the distance traversed in each minute was 97 divided by 110, or $52\frac{10}{11}$, nearly 53 miles an hour—a speed which, he confessed, if he had not evidence of it, he could scarcely have believed to be within the bounds of mechanical possibility. The engine which performed this feat had driving wheels of $5\frac{1}{2}$ feet diameter; their circumference would be $17\frac{1}{4}$ feet. Taking the speed at 53 miles an hour, it was within a very minute fraction of 80 feet in a second of time. This was not the greatest speed of the engine, but the average speed spread over 97 miles, and there could be little doubt that it must have exceeded sixty miles an hour during a considerable portion of the distance. Dr. Lardner concluded by saying, "there was as yet nothing to satisfy us that a much greater speed was attainable by the adoption of the very large scale or gauge of railway which had been thought desirable by those who were interested in the Great Western Line."

Lecture II.

In this lecture the Doctor directed attention to a remarkable line of distinction which existed between inclinations upon railways of different kinds. If, for instance, they had a gradient which would fall at the rate of one foot in a thousand, the train would not roll down, because the gravitation would be insufficient to overcome the mechanical resistance. But suppose the acclivity were increased, so that the gravitation would just balance the friction, that inclination would be what in mechanics was called the angle of

---

* Both places are said to have been washed by the sea.—Vide map, &c., "Camden's Britannia."

repose. The amount of this inclination had been made the subject of much dispute; but it had been generally assumed to be 1 in 250, or at the rate of about twenty feet in the mile. Any inclination greater than this would cause the train to move down spontaneously; and it had been assumed in railway investigations before committees of parliament, that the train, under such circumstances, would double its velocity every second of time. The inevitable conclusion to be drawn from this was, that if they had a steep inclined plane of sufficient length, the consequence would be an indefinite increase of speed till they actually acquired a velocity of 1000 miles an hour. Now, they would after this hardly credit the results which actual experiment gave. Nothing could be easier than the problem to determine the actual resistance from the motion of trains on railways, because it was a matter of easy mathematical calculation to predict what the velocity acquired at the end of the first minute would be, and, according to the rule laid down, that it would be twice as great at the end of the second minute, and so on. By comparing this with the velocity the train actually acquired, the comparison would furnish them with an easy clue. Upon this principle, Dr. Lardner had proceeded in a series of experiments made on the Whiston Plane, which has a fall of 1 in 96. They had four coaches, the gross weight of which was $15\frac{1}{2}$ tons, and these coaches were propelled along the summit level to the brink of the plane, until a velocity of about 29 miles an hour was given to them, and then the engine was detached, leaving them to move down. By means of stakes placed on the side of the line, they were enabled to register the length of time it took to descend every successive 110 yards. They commenced their descent from the summit of the plane at a velocity of nearly thirty miles an hour, which, in a very short space of time, increased to $31\frac{1}{4}$ miles an hour, and then they found that gravity could do no more for them. Instead of going at the frightful velocity anticipated by parliament, they found they got into the most uniform rate of motion at the third or fourth stake, after which there was no increase of velocity whatsoever; and at this uniform motion they continued to descend till they reached the end of the plane. They submitted this experiment to all possible tests, by increasing the weight of the carriages to 18 tons, but it only gave them an increased velocity at starting of $33\frac{3}{4}$ miles, the train descending at a uniform speed the remainder of the distance.

Upon these experiments Dr. Lardner proceeded to remark—"There is an important thing connected with this which I will briefly explain to you. The force that moves the train down an inclined plane is, as you will see, the gravitation of the weight of the train down the plane. This gravitation would, until altogether balanced by some resisting force, acquire an accelerated motion. So long as the resistance to the descending train is less than the gravitation down the plane, so long will the excess of gravitating force down the plane produce an acceleration of velocity, be it more or less. But as soon as the resistance becomes equal to the gravitating force, then there will no longer be any acceleration; the train will no longer acquire an increasing speed. On the other hand, it will not lose speed; if it did, then the inference would be, that the retarding force exceeded the gravitation; out they acquire an equilibrium, and as soon as the resisting force increases to that point that it is exactly equal to the gravitation, then the motion is uniform. The inference we deduced, therefore, was this:—that at $31\frac{4}{10}$ miles an hour, the gravitation of this train down the plane of 1 in 96 was equal to the resistance; in other words, that the resistance to that speed was $\frac{1}{96}$ part of the weight. And you will see that a necessary consequence of this is, that a train of equal weight, placed on a level, and drawn along a level at the same speed of $31\frac{1}{4}$ miles an hour, the resistance which it would oppose to the moving power would be $\frac{1}{96}$ part of the whole load. This alone will show you the extent of the error which these experiments exposed; for the common notion before was, that the resistance in all cases was $\frac{1}{250}$ part of the load, or somewhere about 9 lbs. per ton; whereas it appeared that it was in this case $\frac{1}{96}$ part of the load, or about 23 lbs. per ton; so that the engineer's estimate would be in error to the inconceivable extent of mistaking resistance of 23 lbs. for a resistance of 9lbs. per ton."

Dr. Lardner stated that he had tried similar experiments on the plane of the Grand Junction Railway, which descends from Madeley towards Crewe, at the rate of 1 in 177 for three miles; afterwards descending at the rate of 1 in 265, followed by another descent of 1 in 330. The coaches loaded at 18 tons were moved down this plane in exactly the same way, the wind being fair, and they got a velocity of $21\frac{1}{4}$ miles an hour, and with this velocity they continued to descend the three planes. On making inquiries of the engineman, he found that the steam was never cut off in descending these planes, so that, instead of accelerating the engines at a dangerous speed, as was anticipated by the parliamentary committee, they were actually insufficient to propel them at a sufficient speed for the work of the road. The result of all the experiments he made on the Madeley plane was, that he never met with an instance of propelling trains down, with a fair wind, at a speed of more than 23 miles an hour. From a comparison of the experiments made at the Madeley and Whiston planes, Dr. Lardner said, "I made a calculation, from which it appears that in the first experiment of the two trains, that portion of the resistance which is due to friction amounted to 96 lbs. only, while that which is due to the atmosphere amounted to 268 lbs. In the second experiment, with eighteen tons, the portion of resistance due to mechanical causes amounts to 100 lbs., while that which arises from the atmosphere amounts to 321 lbs., at only 33 miles an hour. One of the objections was, that the train was too light, and that no fair inference could be drawn from four carriages. We, therefore, tried trains of six and eight carriages. Several experiments were made down very steep planes—that of Whiston being 1 in 96, and that of Sutton 1 in 89. In the first experiment of six carriages, the wind was against us. Down the plane of 1 in 89, we could not get more speed than $32\frac{1}{3}$ miles an hour. At this speed the resistance was equal to the gravitation. But with the wind favourable down the same plane, we got $37\frac{1}{2}$ miles an hour, and a mean of these two would be about 35 miles an hour. On the Whiston plane, 1 in 96, with the wind adverse to us, we only got $27\frac{8}{10}$, or nearly 28 miles an hour, but with the wind favourable, we got 34 miles an hour, the mean of these being about 31. In both these cases, both on the Sutton and Whiston planes, you see the evident effects of the wind. The mean of the two, in these cases, gives, on a less steep plane, a less velocity than on a steeper plane the mean did in the other cases. It is remarkable, and very satisfactory in confirmation of the former experiment, that we had six carriages in a calm descending the Sutton plane, and what was our uniform speed? $35\frac{1}{3}$ miles an hour, the atmosphere being calm. In two other cases down the same plane, with adverse wind, we got a speed of $32\frac{1}{3}$ miles an hour; with favourable wind, $37\frac{1}{2}$ miles, the mean of which is $35\frac{1}{2}$ miles; so that in a calm we got a mean between the speed with a favourable and that with an adverse wind. All these harmonies in the results are so many corroborations of the principle which they develop."

Lecture III.

In this lecture the Doctor explained a variety of experiments made on railways, in order to ascertain the source of resistance. He found that an enlarged temporary frontage constructed with boards, of probably double the magnitude of the ordinary front of the train, caused an increase of resistance so trifling and insignificant as to be entirely unworthy of account in practice. Seeing that the source of resistance, so far as the air was concerned, was not to be ascribed to the form or magnitude of the front, it next occurred to him to inquire whether it might not arise from the general magnitude of the train front ends, top and all. An experiment was made to test this; a train of waggons was prepared with temporary sides and ends, so as to represent for all practical purposes, a train of carriages, which was moved from the summit of a series of inclined planes, by gravity, till it was brought to rest; it was next moved down with the high sides and ends laid flat on the platform of the waggons, and the result was very remarkable. The whole frontage of the latter, including the wheels and every thing, a complete transverse section of the wagons, measured 24 feet square, and with the sides and ends up, so as to present a cross section, it amounted to nearly 48 square feet. The uniform velocity, attained on a plane of 1 in 177, without the sides up, was nearly 23 miles an hour; whereas, with the sides up, it was only 17 miles an hour; so that, as the resistance would be in proportion to the square of the velocity, other things being the same, there would be a very considerable difference, due to that difference of velocity. Then, at the foot of the second plane, while the sides were down, an undiminished velocity remained of $19\frac{1}{3}$ miles an hour, whereas, with the sides up, it was reduced to $8\frac{1}{2}$ miles an hour; so that a very extensive difference was produced. They would see at once, that this was a very decisive experiment to prove that the great source of resistance was to be found in the bulk, and not the mere section or the form, whether of the front or the back of a train; but simply in the general bulk of the body carried through the air. It was very likely to arise from the successive displacements of a quantity of the atmosphere equal to the bulk of the body; or still more probably, from the fact of the extensive sides of the train; and indeed there was little doubt that the magnitude of the sides had a very material influence; for, if they consider what is going on in the body of air extending from either side of a train of coaches, they would soon see what a mechanical power must be exercised upon it. Thus, when a train is moving rapidly, the moving power had not only to pull the train on, but it had to drag a succession of columns of air, at different velocities, one outside the other, to a considerable extent outside the train; and it did more, for it overcame their friction one upon the other; for as these columns of air were at different velocities, the one would be rubbing against the other; and all this the moving power had to encounter. This would go far to explain the great magnitude of resistance found, and its entire discordance with any thing previously suspected.

Dr. Lardner next proceeded to consider the practical bearings which the experiments he had detailed would have on the construction of railways. From these experiments a two-fold fact was deducible: first, there was unquestionably a great amount of resistance, and secondly, this resistance had a material dependence on the velocity; it diminished in a very rapid proportion as the speed was diminished. If, therefore, by slackening the speed, they could relieve the engine from any considerable portion of the resistance opposed to it, they had at once a ground for throwing overboard all the objections which had been raised against sections of railways which had considerable gradients. It was asserted that the resistance was a resistance quite independent of the speed, and that its average amount was quite equal to the gravity down a plane with a fall of twenty feet a mile. Both propositions had been proved to be false. The resistance was not constant; it depended on the speed, and its average amount was equal to a great deal more than twenty feet a mile. The gradient that represented the average resistance, instead of being twenty feet a mile, was probably fifty feet; and instead of having no power of limiting the speed, they had a power to which there was scarcely a practical limit. The lecturer stated that he had been ridiculed for the opinion he had advanced before the committee of the House of Commons, that the Southampton Railway Section, of twenty feet to the mile, was as practically good as that of the Great Western, which was on a dead level. He had made that assertion on the ground that in the descent there would be as much advantage gained as disadvantage to be encountered in the ascent; and, except the inconvenience which would result from the inequality of speed, being at one time fast and at another time slow, there would be no other inconvenience or disadvantage worth mentioning. And, therefore, he did contend that it was an extremely improvident and unwise expenditure to lavish millions in cutting through elevations and filling up valleys by large embankments, and constructing tunnels and viaducts, and all the other expensive works, to obtain a dead level. Experiments had since been made which proved the conclusions he had arrived at to be substantially correct. These experiments had been made by Mr. Wood, the engineer of the Liverpool and Manchester Railway, on the Grand Junction Line. A train of twelve carriages, each weighing five tons, was attached to the *Hecla* engine, the gross load being about 82 tons. This was started from Liverpool to Birmingham, under peculiarly favourable circumstances as regarded the calmness of the day and the state of the weather, the engine being allowed to do its own work, unassisted on the various inclines; the velocity of speed throughout the whole way from Liverpool to Birmingham and back again from Birmingham to Liverpool, was, of course, accurately ascertained, and if the theory which he had endeavoured to develop was correct, they ought to find that the average speed in ascending and descending the inclinations would be nearly equal to the speed they obtained on the level parts of the line. There were several planes along the line, and taking the steepest first, viz. 1 in 177, they ascended that plane at the uniform velocity of 22¼ miles an hour, and descended it at the rate of 11¼ miles an hour, the average being as nearly as possible 31¾ in ascending and descending. The ascent and descent of the other gradients on the line gave the same, or very nearly the same, results—the average speed varying little from 31 miles an hour. There was a considerable portion of the line level, and the speed upon that portion was 31 miles, being just the same, allowing for inevitable small discrepancies, as the average speed upon the inclines up and down the line. The plain inference which Dr. Lardner drew from these experiments was this: that the trains between Liverpool and Birmingham performed their journeys in just as short a time as they would do if the line was a dead level from terminus to terminus. He, therefore, considered it unadvisable to expend money in attaining very flat sections, gradients not exceeding thirty feet a mile being, in his opinion, practically as good as a flat and dead level.

Dr. Lardner next observed that it was inexpedient to lavish money in avoiding curves of a less radius than a mile, as no danger could, he believed, attend a curve having a radius of half a mile, perhaps less. It was, likewise, apparent that it was useless to lavish capital on expedients for greatly diminishing friction; such, for instance, as the adoption of wheels of a large diameter, for it was clear that friction afforded but an insignificant part of the sources of resistance, while, by increasing the bulk of the carriage, they gave a greater frontage, and increased the resistance from other causes. Further, observed Dr. Lardner, it seemed probable that they should not with practical trains attain, in the present state of mechanical science, those extraordinary speeds which they were accustomed to hope for some time since. It was not at all likely that they should ever move at the rate of a hundred miles an hour, for the resistance due to the velocity would increase in so enormous a proportion, that it would become an opponent too formidable for any available power to overcome; still less was it likely that those speeds would ever be obtained with profit. Upon this subject Dr. Lardner remarked, "In some experience of railway travelling, I have never witnessed a speed exceeding 45 miles an hour; I did once accomplish that speed with four coaches, but only for a short distance. Mr. Woods has told me, that he has himself gone 48 miles an hour; but that was not for any considerable distance. Let it be remembered, that great speed might be attained in this way. You may get an engine with plenty of steam; you may screw the safety-valve down so as to get a surcharge of steam; you may put no load on the engine, so as to diminish the resistance; and you may run it down a gradually declining gradient till you exhaust all the steam in her boiler upon a falling gradient. Then, if all these things be done, if the rails be clean, and if a correct account be kept, then there will be no denying that great speed has been attained. But when we speak of great speeds, this experiment, the whole length of the Grand Junction Railway and back, at the average rate of 31 miles an hour through the whole distance, with twelve coaches, was a very respectable performance indeed, in the present state of locomotive power."

Lecture IV.

Dr. Lardner said there were two principles on which railways were generally constructed:—First, by departing as little as possible from the natural surface of the ground, and distributing the inclinations very generally and evenly over the whole length of the line, in which case such power was given to the engine as to make it pull up the requisite loads with requisite speed. Others, on the contrary, proceeded on the principle of concentration, and instead of distributing the inclinations over the entire length, they threw them all into one place, as in the case of the Whiston and Sutton planes on the Liverpool and Manchester Railway, and it followed, as a necessary consequence, that the engines which were adapted for working the greater part of such lines nearly on a level, could not easily draw the loads up the inclination, which must therefore be done by additional engines; but if it had been expedient to make the whole line with inclinations like those of the Whiston and Sutton planes, there would not have been the least difficulty in working it, and those planes would have been ascended with just as much speed as that part of the line was now traversed which was nearly level.

Dr. Lardner next proceeded to consider the source of the power of the engine, the manner in which it was produced, and the mode in which it was adapted to use. They should naturally suppose that an element in engine-making of such vital importance as the quantity of surface which ought to be provided to receive the action of fire, in order to produce a given quantity of evaporation, ought to be known to engineers, but they would probably be surprised to find that even the best engineers were as ignorant of it as themselves. No two of them could agree, and they differed, not only in small quantities, but even as much as 100 per cent. Another thing of importance was the magnitude of the grate. Some held, that a square foot of grate per horse power was sufficient; some allowed more, and some less; but generally speaking, three quarters of a square foot was allowed. In the application of fuel there was also considerable difference. It might be applied so as to produce considerable effect, or so as produce comparatively little effect. In this consisted what was called the art of stoking; and in no place was this worse done, in no place did it need to be better done, than on board ships. The coals should be spread lightly upon the grate; and when in a state of incandescence, the stoker should push it back, and lay on more coals. The first effect would be, that the coals first laid on would be coked. The heat would be so great that the gaseous part would be expelled. These gases would be impelled forward by the draught; and as they passed the incandescent coal, they would be consumed, and no smoke would issue from the chimney, the smoke being the unconsumed part of the fuel. As soon as the coke at the back was consumed, the stoker should push back that in the front, and introduce a further quantity of fuel. This would make a common furnace, in fact a smoke-consuming furnace, and there would be a uniform evaporation of steam. But was this the practice observed? By no means. Neither in marine boilers nor in land boilers had the stoker any idea of taking any such pains; he adopted not the most efficient way, but the way most comfortable to himself. He proceeded in this way: he let the fire in the grate be nearly out, he then put in an enormous quantity of coal; the consequence was, the very instant this was laid on, there issued an enormous quantity of smoke, which might be frequently seen issuing from the chimney of a steam-boat. That went on for some time, till at length the chimney got a little rest. This was nothing more than the effect of putting on fresh fuel; and the smoke continued till it was burned red, and it suited the stoker's pleasure and convenience to open the grate again. In some of the best conducted government vessels this was not allowed. They paid their stokers sufficient wages, and made them do their work; and on the *Medea*, for instance, there was no smoke from the chimney at all. There was nothing new in this. Mr. Watt proposed it; and in his factory at Soho, smoke was never seen issuing from the chimney. The only effectual remedy which could be devised would be to feed the furnace by self-acting grates. One had been invented in which the grate was made circular, and it revolved. The feed of coal was placed in a hopper, and the coal passed through it like a funnel. The coal was put in that part of the grate furthest from the flue. This machine was kept in motion by the engine itself, so that to a furnace of this kind there was little necessity for the attendance of men at all.—*Midland Counties Herald.*

THE FRENCH HISTORICAL COMMISSION.

(Extracted from the Gentleman's Magazine for February, 1840.)

The Report on the labours of the Committee of Arts and Monuments is so extremely interesting, that, were it not too long, we should be inclined to translate the whole. The object of this Committee is not only to publish a complete survey of the monumental antiquities of France, but also to provide for the preservation of the monuments themselves. A series of printed questions is sent to every parish throughout the kingdom, in order to obtain the primary information to regulate the proceedings of the Committee in this survey. The undertaking will require many years, and much money. Those districts and monuments will be taken first in order which are of the greatest interest, or are most important in their character, or which are in the greatest danger of perishing; for the Committee has established it as a rule, that an edifice which is threatened with ruin shall always be preferred to a monument which is in a good state of preservation. At present this Committee is occupied in the publication of specimens or models of the different forms which its labours will take. These are to be, 1, the complete survey in description and delineation of the cathedral of Noyon, as a specimen of severe ecclesiastical architecture, and, 2, of that of Chartres, as being the most extensive and superb ecclesiastical edifice in France; 3, the Roman, Merovingian, and Carlovingian antiquities of Paris, as a specimen of the mode in which the great towns will be treated; 4, the description of the arrondissement of Rheims, as a model of the monumental statistics of the provinces.

"The mission of the Committee is, in fact, to search *notre France monumentale*; to catalogue, describe, and delineate all the objects of art scattered over our soil; to draw up an archæological register, so succinct that the monuments of every age and of every kind may be mentioned in it, and of such an extent that every work of art may obtain in it a place proportionate to its esthetic or historical value.

"Two orders of works are therefore to be prosecuted under the direction of the Committee: statistics for all the monuments without exception; monographies for those monuments of importance which could not be developed sufficiently in the statistics. The Committee cannot itself execute all the statistics, which will amount to eighty-six if we proceed by department, and to three hundred and fifty if we proceed by arrondissement, and give separately the statistics of several large cities, which seems desirable and necessary to produce a complete work. Neither can the Committee undertake directly all the monographies, which will amount perhaps to three hundred, which is nearly the number of the important monuments in our country which appear to merit a special work. Time and money would be wanting for such a colossal work. On the other hand, it would not do to let the designs of the Committee be regulated by chance, or to abandon them to the individual caprices of all those who might think proper to undertake an historical work on the monuments. It has therefore been thought indispensable to fix an uniform plan, and to apply it invariably to everything that shall be undertaken, without as well as with the Committee.

"Two means of attaining this result offered themselves; both have been adopted. In the first place monographies and statistics will be given as models, to which all future monographies and statistics will conform, as well in the scientific plan as in the material execution. Next, instruction will be sent to all the correspondents, and to all the antiquaries in France, to indicate the plan according to which their researches must be made, to fix the expressions which are to be used in the description of a monument, and the characteristic signs which serve to class the works of art, and to determine their age.

"As to the statistics, they will be of two kinds; those which include all the monuments of an arrondissement, and those which only comprehend the monuments of a great town.

"For the model of the statistic of an arrondissement, that of Rheims has been chosen—one of those which are most numerous in communes, and one of the richest in monuments. An architect of Rheims, M. Hippolyte Durand, has been employed to make all the drawings; the archivist and librarian of the same town, M. Louis Pâris, will write the history of the edifices; the secretary of the Committee, M. Didron, will give the description of all the monuments which will be represented by engraving and lithography.

"Paris has been chosen as the model of the statistic of a great town. This work has been entrusted to M. Albert Lenoir, who will give drawings and descriptions of all the Roman, Merovingian, and Carlovingian monuments which formerly adorned the town of Paris, and which have left numerous and imposing ruins. Paris, which possesses monuments of all epochs, from Julius Cæsar to our own days, will serve as a type for those great towns in France, Lyons, Rouen, Bordeaux, and Strasbourg.

"The Committee will give also two models of monography; for, the monuments of France being splendid or austere, it is necessary to take a severe monument and a sumptuous one.

"The cathedral of Noyon, graver still since the revolution and the course of ages have broken the statues of its portal and its painted windows, has been selected as the type of a church at once severe and original. By an exception which is rare in France, this cathedral is rounded at the extremity of its transepts, as at its apsis, and it is fronted by a porch on the west. M. Ramée has just finished the drawings of this curious monument, and M. L. Vitet, member of the Chamber of Deputies, is preparing the text.

"The Cathedral of Chartres appeared to be the monument the most complete and the richest in France—we may almost say, in Europe. Nôtre Dame de Chartres is a cathedral far more considerable than the others, by its crypt, which extends the whole length of the building; by the numerous sculptures which decorate its royal portal and its lateral porches; by its two western spires, perfect models of the architecture of the twelfth and of the fifteenth centuries; by the six *amorces* of towers which rise at the *croisillons* and at the apside; by the delicate sculptures which adorn the enclosure of the choir; by the painted glass which fills all the windows; by a great chapel—we may almost say, a little church—which the fourteenth century has attached to the great edifice of the thirteenth.

"The drawings and text of this monography appeared to be of too high a degree of importance to be entrusted to a single person. Two artists have been joined together for the graphic work: MM. Lassus, architect, and Amaury-Duval, painter. M. Lassus will make all the drawings of architecture and decoration, and will make the plans, and give the sections and elevations; M. Amaury-Duval will draw all the sculpture. The text itself, which will accompany and explain these numerous designs, will also be divided. In a literary work on a monument like Nôtre Dame de Chartres, there are two parts which are very distinct: the history of this monument, which relates its foundation, its vicissitudes, the life of the personages who have inhabited it, so to speak, that of the bishops who have adorned, enlarged, and modified it, in fact the history of its former times; and the description which tells its present state, which describes by language all its stones one after another, all the statues, all the figures painted in fresco or on glass, all the various forms which sculpture has impressed on different materials to give them a character, a style, which indicates an epoch, an age. The history of a monument, in fact, is still more different from its description, than architectural drawings are from drawings of figures; and, since there were two artists for the graphic part, it was but logical to make the same division of the literary part of the undertaking."

Besides doing all that may be possible to preserve the ancient monuments from ruin, the Committee of Arts and Monuments has taken measures to form a Museum of National Antiquities, in which the fragments of such monuments, as their endeavours have not been able to save from destruction, may be deposited.

"In spite of the zeal of the correspondents, in spite of the ardour of the Committee itself in defence of monuments threatened by men or ruined by time, many objects of art perish, many edifices fall; and, since there exists no place destined to receive the fragments, we lose even the last trace of the most interesting monuments. Since the destruction of the museum of the Petits-Augustins, our national archaeology has sustained losses of this kind which are irreparable. Latterly, when the restorations were made at the church of St. Denis, when the mutilations were perpetrated on the church of St. Benoit, when the churches of St. Come and of Cluny were demolished, they were forced to throw away among the rubbish bases and capitals of columns, sculptured tumulary stones, carved frieses and gargoyles, because the royal museums which are consecrated to pagan antiquities, cannot and will not receive national antiquities. Such a state of things could not last long without the greatest detriment to history; for no archaeological studies are possible without monuments, and the monuments become rarer every day.

"Struck with these injuries inflicted upon art and historical studies, the Committee, on the proposition of Baron Taylor, begged the Minister of the Interior to grant a place for the temporary reception of the objects of art scattered in a thousand places, and which may be collected together. Afterwards, the necessity will be felt of forming a gallery of the fragments which will be gathered by little and little at a small expense, and we shall thus have a museum of Christian antiquities, which may be compared with pride to the museums of pagan antiquities. In this museum, besides the pieces which are originals, may be placed, as has been done at Louvre for the Greek and Roman monuments, plaster-casts of the finest works of art, statues, and bas reliefs which decorate our edifices of the Middle Ages. Several provincial towns already possess a Christian museum; Paris must not be behind Dijon, Orleans, Puy, Mans, or Carcassonne. The Minister of the Interior received in the most favourable manner the proposition of the Committee, and has made a formal promise to dedicate the church of St. Martin-des-Champs, now dependant on the Conservatory of Arts and Manufactures, to the reception of the fragments of Christian architecture and sculpture which may be collected at Paris and in the departments. This church, which, with St. Germain-des-Prés, is the oldest in Paris, is also the most curious for the originality of its construction and decoration; it is admirably fit for its new destination—the casket will be worthy of the precious objects which it will contain. The Minister of the Interior has promised to cause to be restored, for the object above specified, this church, which threatened to fall into ruins from the effects of age, or which was going to be demolished to make room for a *mairie*. The Committee regards this result as one of the most important it has yet obtained, and knows not how to thank sufficiently the Minister of the Interior.

"When a monument falls of itself, as has lately happened to the church of St. Sauveur at Nevers, the Committee will have but one resource, and that one it will use immediately; this will be to send an architectural draughtsman to the scene of the disaster, and to give him the task of collecting, or causing to be preserved in a museum, all the valuable fragments which may not be broken to pieces; of drawing, on the faith of traditions, on the inspection of old engravings, and the examination of the locality, a plan, sections, elevations, details; of stating, in a circumstantial report, the cause of the accident, in order to prevent the fall of monuments which may be threatened with ruin under the same circumstances. The draughtsman will return to Paris with the fragments, which will be placed in the museum,—with the drawings, which will be engraved,—with the report, which will be published. Of the ruined monument will be presented at least its portrait and some fragments. This is precisely the mission which, in the case of St. Sauveur, the Committee has entrusted to M. Robelin, architect, non-resident member of the Committee, and charged with important works in the Cathedral of Nevers, his native place."

All the evils here mentioned and provided against, are felt equally, if not more, in England; our national antiquities are daily perishing; we have no museum to receive the fragments, no public spirit in our government to provide for them, and only here and there a solitary individual who, at his own risk and inconvenience, will use his exertions to preserve, will afford a shelter to what can be saved, or will publish, or cause to be published, drawings and descriptions. We rejoice at the exertions of our neighbours, though we have reason to be ashamed at being left so far behind them. Yet we think we see at home a new spirit rising and spreading itself, and we hope that it may bear its fruit before it be too late.

We ought to add, that the Committee of Arts and Monuments is publishing manuals of the different branches of archæology, drawn up by the first scholars in each branch, and intended more particularly for the use of its correspondents, to draw their attention to the different points most necessary to be observed, to fix a standard to guide them with certainty in their researches and observations, and to give with accuracy and certainty that elementary knowledge which is necessary to enable them to work efficiently.

MESSRS. FAWCETT AND CO.'S ENGINE FACTORY, LIVERPOOL.

(From the Liverpool Standard.)

The object of the establishment is principally the construction of marine and other steam engines, mill machinery, pieces of ordnance, and other heavy articles of the foundry and the forge, which here pass from their rudest state, through the various requisite processes, until they are turned out bright and perfect from the hands of the finishers. The magnitude of the works may be estimated from the facts, that the premises stand upon an area of many hundred yards; that that space, nearly covered by lofty buildings, is found incommodiously small; and that the number of workmen employed in the various departments considerably exceeds seven hundred. The writer of this was a few days ago politely permitted to view the works, and was furnished with such information as the shortness of his visit would allow, by one of the partners, as well as by an attendant. We shall now notice the several departments under their respective heads, and shall conclude with some particulars of the fine marine engines now in a state of forwardness.

Founding and Boring of Cannon.

On entering the yard the attention of the visitor is arrested by the great number of cannons of various sizes and calibres, from swivels and half-pounders to thirty-two pounders, ranged on the ground, or peeping, in carriages, with portentous aspect, from door-ways, entrances, and corners. The large guns are of various fashions, some being cast from the plain models used in the French navy, others from those of the Dutch, and others (the handsomest to our thinking) of the more decorative form approved in England. In casting these guns (all solid), what is called "a head" is cast along with them, at the muzzle end, having the appearance of a plug or long tompion. This is cut off before the boring is commenced. At the breech, too, an additional square piece of the metal is cast on, by which the gun is turned by machinery while it is being bored, the borer being stationary in the operation. When outwardly cleaned and finished (with the exception of drilling the touch-hole and fixing the lock), the gun is placed horizontally, and secured so as to turn without vibratory motion. The machinery is then applied, and the gun turns rather slowly, advancing with an even pressure upon the large steel boring instrument, and continually discharging the metal which it cuts out. The gun has to be bored two or three times, according to its calibre, and when the operation is completed the bore is as bright and true as that of a fowling piece. The touch-hole is afterwards drilled out with great nicety, as are the holes, in raised portions of the breech, for the fixing of the flint lock, which has now in gunnery almost superceded the use of the match. Several guns are bored daily and simultaneously, to meet the demand at home and abroad, and a large "assortment" is kept constantly on hand to supply those governments and individuals who are bent on "mischief" or self-defence. Amongst the pieces of ordnance now in preparation or finished at the works are :—

26 thirty-two pounders, for a French house.
20 twenty-four pounders, another French order.
4 twelve pounders, for the same.

The Foundry.—This part of the works differs from most other foundries only in the immense weight of the castings, which, from the size of the building, and the number of blast furnaces, cranes, &c., may be turned out. Single pieces of twenty tons each might be accomplished, if required. The operation is interesting, but it is too generally known to require detail. The article to be cast is moulded (in sand) from wood, and enclosed within iron frame-work, a hole being left for the entrance of the metal. The metal (cast-iron) is thrown, in broken pieces, mixed with coals, into a large cylindrical furnace, the blast thrown into which, by machinery, with great force, makes a roaring noise, and soon brings the whole to a white heat. The metal, as it melts, sinks to the bottom. When all this is ready, a perforation is made with the point of an iron rod, through a sort of doorway at the bottom, which at that point is stopped up by fire clay. The boiling metal immediately rushes out in liquid white fire, and is received in pots with three long horizontal iron handles, two at one side, like those of a hand-barrow, and one at the other. By these it is carried by three or four men, according to its weight; and if the casting or castings be comparatively small, the metal is poured at once from this into the moulds, the pot being turned by the men holding the two handles. If, however, the casting be large, the smaller pots full of liquid metal are discharged into a cauldron of sufficient size, and this, from its great weight, is hoisted by a crane and placed over the casting, where it is discharged, in a careful manner, of its contents. The air, forced out of the sand by the metal, frequently makes a loud explosion, (as we witnessed,) and when the intense heat of the hissing iron perforates the outer portions of the same, blue and sulphureous looking flame issues from the sides in all directions. When the metal is sufficiently cooled, the frame-work is removed, and the castings taken out. Here may be cast any article, from a lath nail to a steam-engine cylinder, weighing from ten to fifteen tons.

The Working Engine on the Works.—On the east of the yard, on each side of which are the extensive buildings, is the larger engine, of thirty-six horse power, which works the greater part of the machinery used in the different rooms, in the several operations of turning, planing, drilling and otherwise "torturing" the obdurate but conquerable metal that falls under the cruel hands of the workmen. This engine is of the old-fashioned principle, with an immense wooden beam, secured with iron, and a large fly-wheel. It is, however, most effective, communicated by cog-wheels and shafts with the several rooms in which the power is applied to the lathes, &c. by drums and shafts. There are also other engines, but of considerably less power.

The Smithy.—This is one of the most extensive portions of the establishment. It comprises two large buildings thrown into one; and a great number of workmen are constantly employed. There is an avenue of anvils, and the constant hammering, the blowing of their fires, together with the dusky visages of the athletic workmen, remind one of the description of the abode of the Cyclops. Here, however, "bolts" are "forged," of which neither "Jove" nor his armourer "Vulcan" could have conceived any notion. All the iron-work for the steam engines is here made, with the exception of the very heavy paddle-shafts, which are brought in the rough from the Mersey Forge.

The Planing-machine Room.—In this room are valuable and elaborately-contrived machines for the planing or levelling of large plates, or other pieces of iron or brass, so as to give them a smooth, true, and polished surface. The article or piece to be planed is securely fixed by screw-bolts, &c., to an horizontal iron table, perforated with holes for the insertion of the bolts from beneath it in any required point, to suit the size or form of the article. This table, when put in motion, travels backwards and forwards, with its load on two iron rails, or parallel slides. Over the centre is perpendicularly fixed what is called the "planing tool," an instrument made of steel, somewhat in the form of a hook, with the point so inclined as to present itself towards the surface of the metal to be planed, as it approaches it on the table, so as, when all is adjusted, to plough or plane it in narrow streaks or shavings as it passes under it. The extremity of the tool is about half an inch to three quarters in breadth, and being of a round form at the under side, and ground or bevelled on the upper, presents a sort of point. If a plate of iron is to be planed, the operation commences on the outer edge, and each movement backwards and forwards of the table places it in such a position under the tool, that another small parallel cut is made throughout its whole length. The tool, in ordinary machines of this kind, is fixed so that it cuts only in one direction, as the plate is drawn against its edge or point, which is raised to allow of the backward motion of the plate. A new patent has, however, been obtained for a great improvement in this respect by Mr. Whitworth, of Manchester, and several of his machines are on Messrs. Fawcett and Co.'s premises. In these, by a peculiarly beautiful contrivance, the cutting instrument, the moment the plate passes under it, "jumps" up a little in the box or case to which it is attached, and instantly "turns about" in the opposite direction, and commences cutting awey, so that both backwards and forwards the operation goes on without loss of time. The workmen very quaintly and appropriately call this new planing tool "Jim Crow." A workman attends to each of the machines, and when the piece to be cut is fixed with great exactness on the moving table, by a spirit level, he has nothing to do but to watch that it remain so, and that the machinery work evenly and correctly. Where a very smooth surface is required, the operation of planing is repeated, and two plates thus finished will be so truly level, that they will adhere together. It should be added, that so perfect are these machines, that in addition to planing horizontally, they may be so adjusted as to plane perpendicularly, or at any given angle.

The Turning Rooms.—In several of the rooms both hammered and cast iron of all possible dimensions are turned, with astonishing facility and correctness, on what are called slide lathes. In one of these we saw the paddle-shafts for the President under the operation. Each of these weighed, when they came from the forge, about ten tons, and they will be but slightly reduced in weight by turning. In the same room large piston and other rods were being turned. While the shaft or rod is revolved, the cutting instrument, fixed to a slide, on which it is slowly and evenly carried along, performs its operations with wonderful precision, frequently cutting a large and continuous shaving of thirty or forty feet in length (as may be,) apparently as if it were lead, and which, curling up, forms a curious and perfect worm or screw. From the great pressure of the tool, one of the edges of this screw is frequently split into regular teeth like those of a fine comb, but shorter. The tool, when it has gone from end to end of a shaft or rod, is, by a simple adjustment, made to travel back again, and the operation is continued till the whole is of the required diameter, and perfectly bright and polished. Another interesting operation in this department is the turning and polishing of circular pieces of machinery, whether dished or flat. The tops or lids of the cylinders of large engines are the principal, and some idea may be formed of the advancement of this art, by an inspection of the cylinder tops of the President, which are as bright as mirrors, and are 80 inches in diameter! Water constantly dropping on the cutting tool from a small pipe, is all the "oil" used either in planing or turning.

The Fitting-up Shops.—There are several rooms in which the "fitters-up" are employed. These finish the smaller brass and iron-work of the engines, and have turning-lathes, and all manner of hand-tools. In the building of an engine, they hold the same relation to the foundry and the forge, that the clock and watch maker (properly "finisher") does to the establishment that supplies him with his wheels and other works in the rough.

The Model or Pattern-Makers' Room.—These rooms are extensive, and many first-rate workmen are employed, the greatest exactness being required, otherwise the castings would be unavailable. The timber used is almost wholly well-seasoned deal. Many of the patterns are complicated and beautiful, a great deal of taste being displayed in the mouldings and other decorations, where such can be appropriately introduced. The models are all finished and polished in the best possible manner.

The Model Rooms.—These are a lofty part of one of the buildings, and are well worthy of a visit. In one of them we were fairly lost, amidst many hundreds of bevelled, cog, and other mill wheels, of all possible sizes, (few alike) and piled up to the very roof. Many of these are, we learned, for the purpose of supplying foreign orders. Here, too, are a variety of engine-bed plates, paddle-wheel centres, patterns for water and other wheels, &c. &c. all made with mathematical accuracy.

In another room were an immense number of models of great guns, as adopted, in outward fashion, by the English, the French, the Dutch, and others. The models of beams for marine engines, of all sizes, were here piled; also of Ionic fluted pillars for their frames. The models from which the beams, &c., of the Royal William, and many others, were cast, are here deposited, as are those of the larger engines in the yard below. The collection of patterns of all descriptions is indeed great and excellent, and must have cost an immense sum of money.

The Engines now in course of completion.—The following engines are now in hand at the works, and the three largest nearly completed:

1 pair of	540 horse power	for the	"President."
1 do.	420	ditto	the "United States."
1 do.	450	ditto	a French man-of-war steam frigate.
1 do.	300	ditto	H. M. S. "Medina."
1 do.	50	ditto	the "Calcutta Steam-tug."*
1 do.	45	ditto	a Government tender.†
1 single engine of	60-horse power,	for	Australia.
1 do.	50	ditto	for a French house.

The President's Engines.—These are the most remarkable for their size, and are really a stupendous piece of workmanship. They are already fixed up, and strike the visitor with astonishment. The castings, and all the workmanship are of the first description, and the architectural design of the framework, or pillars, is highly ornamental, without any sacrifice to the requisite strength. As probably the most suitable to attain this desideratum, the Gothic style has been adopted. The massy clustered pillars are surmounted by the pointed and moulded arch to correspond. The diagonal stays and their open work are in keeping; and such is the height and imposing effect of the whole, that visitors generally remarked that it strikingly resembled a handsome Gothic chapel. The beams are beautiful castings, as are the cylinders, and both of immense size and weight. The polished iron and brass work is superb, and the whole furnishes a gratifying proof of at once the enterprise and the ingenuity of the men of England. The following are some interesting statistics of this stupendous piece of machinery:

Diameter of cylinder..............	80 inches.
Stroke of engine	7 feet 6 inches.
Weight of cylinders	11 tons.
Valve-cases, from	6 to 6½ tons.
Beams (4 in number), upwards of ..	5 tons each.
Condensers, about	10 tons.
Gothic pillars, four pairs, each	11 tons, 7 cwt.
Diagonal stays, 4 in number, each....	4 tons.
Main, or paddle shaft..............	9 tons.
Two eduction pipes, each	18 cwt.
Boilers, each	30 tons.
Bed-plates, (two,) each in one casting	15 tons.

The whole engines and boilers, with the water, will weigh about 510 tons.

The hoisting-tackle used in setting up these engines is well worthy of notice. On the principals, or lower beams of the roof, which are of extraordinary strength, railways are fixed, upon which traversed scaffolds, railed round, and each carrying a powerful winch. On these scaffolds are also railways, at right angles with those on the beams, so that, by moving the scaffolds and the winches, any spot in the building may be attained directly perpendicular to the article to be hoisted, which, by other movements, can be lowered to any given site.

The Engines of the "United States."—These are precisely similar in construction to those of the President, differing only in being a little smaller. No detailed notice of them is therefore required. The cylinders are 73½ inches in diameter, and the power is the same as that of the Great Western,—namely, 420. They are erected in the same shed, or building, containing those of the President, and have been equally admired.

The "Medina's" Engines.—These are of 300-horse power, and though different in the style of the casting, are also got up in the best manner.

The whole three pairs of engines will be ready simultaneously for shipment; but, unluckily, the want of want of proper shears to hoist in the machinery and boilers, (there being but one pair at the Canning Dock, and a crane at the Trafalgar,) one or other of the vessels will have to wait her turn.

The pair of 45-horse power engines, for the Admiralty, are also in a forward state; as are most of the others before enumerated.

Such is a sketch of the works at Messrs. Fawcett and Co.'s establishment. We do not remember to have enjoyed a greater treat than in visiting it, and it was with considerable reluctance, that having other engagements, we could not prolong our stay on the premises, and examine some other departments. The whole is a world of mechanism within itself; and though it send forth huge and deadly weapons of war, it also produces maritime machinery calculated to extend civilisation, and to promote the amicable commercial intercourse, and mutual wealth and happiness, of nations scarcely known to each other but by name.

This firm have upwards of 700 workmen. The President will be the largest steam-packet in the world. Messrs. Fawcett and Co. have been applied to by the Bristol Steam Packet Company to make them engines of 600 horses' power each, but their present engagements do not permit of their accepting the order.

* Now building in India.
† To run, it is said, between Dover and Calais.

DESIGNS FOR LAYING OUT THE ROYAL BOTANIC GARDENS. INNER CIRCLE, REGENT'S PARK.

The Council of the Royal Botanic Society being desirous of giving every opportunity of securing the most efficient assistance in laying out their Gardens in the Inner Circle of the Regent's Park, announced some time ago their intention of giving a premium of fifty guineas for the best design submitted to them. During the last month the designs were exhibited for inspection in the rooms of the Society, in Pall Mall, where they have been visited by many persons connected with the Society, and by artists. It is probable that the rooms will remain open for a few days longer, previous to the decision of the Committee, until which time any of our readers would doubtless be able to obtain access to them.

The instructions drawn up for the guidance of candidates in some degree, limited them both as to the nature of the plans, and the kind of drawings they were recommended to send in. The instructions directed that a large portion of the ground should be devoted to a geographic arrangement of the plants in twelve separate compartments; the gardens should be provided for the special study of plants, as regards medicine, agriculture, arts and manufactures, scientific arrangements, and experiments; that proper conservatories and buildings should be provided. The plans were restricted to a scale of fifty feet to an inch, and it was stated that sections and detailed plans were not required. The number of designs sent in is above twenty, from many men of eminence and respectability, principally architects, but the exhibition as a whole does not show that talent which might be expected.

1, is merely a plan of the grounds in their present state.

2, by H. P., Spring Terrace, Wandsworth, is distinguished by two principal features, a nascent yearning for some hot water apparatus which is in futuro, and a parade of Owen Jones's Alhambra, the Alpha and Omega of the inventor's artistical knowledge, from this he has sucked the inspiration of a court in the Moorish style, and of a flight of steps decorated with *azulejos.* These our readers know are painted tiles, and unless he could resuscitate the Andalusian artists, we fear that they would be little better than the antiquated Dutch tiles, long since consigned to the chimney corner. The design, if it may be so called, is to form an endless walk in the gardens, so that you would never pass over the same path again.

3, by John Aiton, of Mr. Pearson's Nursery, Hampstead-road, is merely a gardener's arrangement of the plants.

4 and 5, by Martin Joseph Stutely, Architect, Gower-street, Bedford-square—5, is the ground plan, and 4 an isometrical perspective view. This design is an adaptation to the present state of the grounds, and consequently meagre. The buildings, mostly Italian, are poor. One excellent feature is a large conservatory on the north side, standing on a raised terrace, which commands a view over the Lake in the Park, and up the Vale towards Hampstead, bringing that fine scenery as it were into the Society's domain. A large raised seat affords a view of Primrose Hill.

6, John Bainbridge, flower gardener to Lord Wenlock, Escrick Park, near York—a botanical arrangement; the walks in a fantastic style; and an imitation of the various mountains on the face of the globe.

7, Alfred Bartholomew, architect, Warwick House, Gray's Inn. There is a want of effect in this design, but the arrangement suggested for the plants is ingenious. The ground is divided by imaginary lines into gores, each appropriated to the plants of some geographical region, and these gores again subdivided by concentric circles so as farther to distribute in each region the plants into the several classes of arts and manufactures, agriculture and science. In the centre is an angular conservatory. The explanations attached to the designs affords many useful remarks. Mr. Bartholomew suggests that the capitals of the columns of the conservatories might be taken from botanical subjects, and made in clay or artificial stone. A canal supplies water all round the garden.

8, W. Billinton, architect and civil engineer, Wakefield. This design is mainly a geographical arrangement, without much attempt at pictoral effect; it seems doubtful also whether the grouping of the buildings would be good. The book of explanation shows an intimate acquaintance with practical horticulture, and contains many good suggestions, particularly with regard to maintaining an equable temperature in the large conservatory by double domes.

9, John Burges Watson, architect, 39, Manchester-street, Manchester-square. This design is illustrated in the margin by sketches of the buildings, many of which are pleasing, the plan however is not effective except with respect to a lake, apparently imitated from a former design of Mr. Henry Laxton;* from whom he seems to have derived other ideas. The reasons

* See a plan of the Royal Botanic Gardens, in the Journal, vol. 1, p. 359.

Mr. Watson gives for the position of the conservatories is good, and the efforts of a cultivated artist are visible in many parts, both of the plan and explanation, which show the results of his experience at Chiswick, where he was employed; he has not however been so successful as on former occasions, when he carried off the fifty guinea prize for laying out the gardens at Manchester.

10, Henry Laxton, F.L.S., and John Thomson, landscape gardener, late head gardener to the Duke of Northumberland. This plan is principally Mr. Laxton's, but we shall dismiss it in a few words, to come to some of his other designs. It is chiefly laid out as a large flower garden, and the compartments exhibit great ingenuity. The book of reference shows great acquaintance with the botanical part of the subject. The conservatory in the centre is circular, with arms in the form of a Greek cross.

11, Henry Heathcote Russell, architect and civil engineer, Springfield Lodge, Garrat, near Wandsworth. A design adapted with much ingenuity to the present state of the grounds—it has, however, the usual imperfection, want of effect. A conservatory is made to run all round the gardens, which however is impracticable, on account of the state of the grounds.

12, Edwin E. Merral, 35, Park Lane, Leeds. This seems to be by the eminent Hollander, 'who wrote a book of boetry as dick as dat,' the crowning idea is a central platform 200 feet diameter, 5 feet high, and surmounted with an iron railing.

13, Henry Laxton, F.L.S., architect and landscape gardener, Adelphi Chambers. Mr. Laxton who had a great hand in laying out the grounds at the Beulah Spa, is the surveyor of the gardens to the Royal Botanic, part of whose grounds he has laid out. He has sent in four designs, all exhibiting great attention to the subject. No. 13 has a lake on the north side, before which is an extensive lawn, most essential to a metropolitan garden, where a large concourse of people is likely to be occasionally collected. In the centre of the gardens is a spacious domed conservatory, and on the south side is the principal building for the official department with a large Italian garden, surrounded by raised terraces with extensive conservatories on each side. The whole of the gardens is surrounded by an arboretum.

14 and 15, Charles J. Nicolay, architect, Elm Grove Cottage, near Winborne, Dorset. The ground plan is accompanied by sections showing buildings in the classic, oriental, and Tudor styles. The conservatories are on a raised platform in the centre, and the scenery on the south front is made attractive.

16, Wyatt Papworth, architect, 10, Caroline-street, Bedford-square. There is considerable variety of effect and breadth in this design. The ground is formed into three divisions. The first devoted to the business part of the establishment is formed by buildings with south aspects, screened at the base by trees. The second which has rock work at one end and the museum, &c. at the other, is an ornamental garden, and has to the south, the grand front, a conservatory, flanked by trees and rock work. The third division as seen from the back of the grand conservatory is a spacious lawn with a back ground of trees and shrubs.

17, Edward Lapidge, Derby-street, Parliament-street. This would be a grand design for St. Petersburgh, but would not be so pleasing here as it is an entire sacrifice of the beauties of nature to architectural effect. On a raised platform in the centre is a hollow square of buildings covering the area of the Great Pyramid or of Lincoln's Inn Fields.

18, is a plan of Mr. Laxton's making the arrangement of the gardens at present, immediately available on an economical scale, the leading feature is a promenade walk, through the centre 30 feet wide; the outer boundary has a winding walk of about three quarters of a mile in length, judiciously laid out for an arboretum.

19, also by Mr. Laxton, is a design much resembling No. 13, but grander in its architectural and horticultural arrangements, so as to produce one mass of variegated effect in the shape of Italian, Dutch and French gardens, rosaries, fountains, statues, casinos, conservatories, terraces, &c.,—if sufficient funds could be raised for carrying out the whole of the design at once, without regard to the present form of the ground, we should prefer this design to any other.

20, G. A. Cheffins, architect, Lees-street, Piccadilly, Manchester, is the only one of the architectural competitors who is very much behind hand. His design is very nearly akin to that of the Dutch gentleman who composed No. 12. It must have puzzled Mr. Cheffins to produce any thing so bad.

21, R. H. Essex, 13, York-buildings, New-road. This is the climax of all that is rich in the ludicrous. A map of the world is laid down as the ground work, and a most farcical distribution of the necessary buildings is made. A gardener's cottage in the centre is at the sign of the North Pole, the lecture rooms are in the Atlantic ocean, (a witty gentleman, thought the Pacific better), the Great Desert of Africa serves as a nursery, the meridian of London is denoted by a sundial, and the capital cities of Europe by sundials. Really, really, Mr. Essex, you must have intended to enliven this otherwise dull exhibition.

LITERARY NOTICES.

A system of Practical Arithmetic by Samuel Young, is intended for the use of the working classes, from whose pursuits the examples are derived. This is certainly a more laudable effort than some of the nauseous affairs which are used in religious schools. The work seems carefully arranged.

On the Construction of the Ark, as adapted to Steam Navigation to India, is an effusion of a Mr. Radford. If our readers have any money to spare for metaphysical experiments, we recommend them to buy this work as a good example of how far hallucination can proceed.

On the supply of Water to the Metropolis.—This pamphlet gives a brief account of the extensive works that have been carried on by the Water Companies for the last five or six years, for improving the supply of the Metropolis with pure water. The author very evidently is a stickler for the existing companies, and ably advocates their cause; but he has allowed his zeal to overstep the mark of prudence. We shall, next month, make some additional remarks.

WORKING EXPENSES OF RAILWAYS.

Abstract of the different items of the working expenses on several lines of Railway now open: showing the ratio per cent. each item bears to the gross Receipts, and the amount of each per mile, for the half-year ending December 31, 1839.

	Name of Line.	Gross Expences. Per cent. on gross receipts.	Gross Expences. Per mile.	Maintenance of Way. Per cent. on gross receipts.	Maintenance of Way. Per mile.	Locomotive Power. † In hands of contractors.

Notes.—The London and Birmingham was chargeable with maintenance of way on 78 miles for six months, and on $34\frac{1}{2}$ more for 15 weeks $= 97\frac{3}{4}$ for 6 months. The other items are upon $112\frac{1}{2}$ miles.

The Grand Junction is chargeable with maintenance of way on $82\frac{1}{2}$ miles —and the mileage of that item is calculated on that distance—but as they carry their traffic to Liverpool and Manchester, on the Liverpool and Manchestar line, the other items are calculated on $82\frac{1}{2} + 30 = 112\frac{1}{2}$ miles.

The Birmingham and Derby maintain $38\frac{1}{2}$ miles of line; but as they carry for 9 miles on the London and Birmingham line, the other items must be charged upon $47\frac{1}{2}$ miles. This line was only opened in August, but the charges are calculated at the same rate for six months.—*Correspondent of the Railway Times.*

Iron Canal Boats in America.—The success of this class of boats in England, with the arrival of the Iron Steamboat at New Orleans from Pittsburg, (of a very light draught of water, carrying a great cargo,) has led to the opinion that iron canal boats, if used on the Erie canal, would double its capacity, and supersede the necessity of the enlargement. We trust that some of our enterprising forwarders will try the experiment. We are not fully acquainted with the cost of these kind of boats, but have been informed, that it will not exceed fifty per cent. on the cost of the best Lake boats. In Penn ylvania, with their mixed line of canals and railroads from Philadelphia to Pittsburg, they now use iron boats, divided into three parts. The iron boat is carried into Market-street, Philadelphia, on the return of the cars, at the Schuylkill canal they are hooked together, forming a complete boat, which afterwards passes the Allegany-ridge, by ten inclined planes, when they again take the canal and river, to reach Pittsburg. With this complicated system, they compete with us successfully for the early spring trade.—*American Railroad Journal.*

Destruction of Wooden Bridges in America by Ice.—The breaking up of the winter has caused a recurrence of a specie of accident which is far from being rare. We allude to the destruction of bridges by the combined force of a swollen stream and immense masses of ice. The liability to this kind of accident depends more upon the character of the stream nearer its source than at the location of the bridge itself. A river of any considerable size receiving the drainage of a large track of country, is of course apt to be speedily swollen by a sudden and heavy fall of rain or rapid thaw, and as one or the other of these circumstances are sure to accompany the breaking up of the ice, such streams must present locations badly adapted to ordinary wooden bridges. Shallow streams, from daming up the ice, are rather worse than others in this respect, yet they are the most frequently crossed by these insecure structures. Bridges of a more durable construction, if not built in the most substantial manner, are likely to suffer from the same cause, if the water way has been too much diminished. The proper substitute in such localities are *suspension bridges* of iron wire. These claim the preference of all others, whether in regard to economy of first cost, or their superior adaptation to the circumstances of the locality. Over a large portion of our country the character of the streams is altogether more favourable to this than any other species of structure. The example of the new bridge at Fair Mount will, we hope, speedily be followed in many places.—*American Railroad Journal.*

NEW INVENTIONS, IMPROVEMENTS, &c.

Improved Mode of Making Bricks.—A correspondent of the *Railway Times* describes a simple method of making bricks adopted on the Great Western Railway on Mr. James Bedborough's contract at or near Marston. It is the invention of Mr. W. B. Pritchard, Esq., Civil Engineer of this Railway, and late of the Chester and Crewe Railway, &c., is as follows:—The clay, only watered, is thrown into a common pug mill (or mortar mill); there it is ground in a similar manner to mortar; the bottom of the mill is divided into four quarters. into which are grooves cut, and under which are placed four moulds of the same kind as those in common use by hand-moulders. Two boys are at the quarters taking the moulds out and placing others in; and by a peculiar knife at the bottom of the mill, which presses the clay into the mould, eight bricks are made every time the horse goes round, which is twice a minute; and at that rate the horse can travel twenty miles in twelve hours, thus making 960 an hour, or 11,520 per day. The bricks made by this machine are much heavier and sounder, and the clay much better tempered, than by any other mode of manufacturing that I have ever witnessed; and the saving is 2*s.* 6*d.* per thousand, besides other advantages, &c.

Moses Poole, Lincoln's-inn, *improvements in apparatus applicable to steam-boilers, in order to render them more safe. March* 11.—The first improvement consists in a mode of applying to the boiler, as a species of safety valve, a metallic plate or disc, which shall burst when the steam in the boiler attains a certain degree of pressure, and thus relieve the boiler, which plate may afterwards be replaced with a fresh one, without stopping the working of the engines. To an aperture in any convenient part of the boiler is fixed a curved tube, terminating in an enlargement or cup, having a ledge running round the bottom for the safety disc to rest upon. Upon the disc is laid a ring, the edge of which is chamfered off, so as not to cut the disc, and this ring is secured down firmly by another ring, which is screwed into the upper part of the cup. The outer bend of the pipe contains water, both above and below the disc, in order to maintain it at the same temperature on each side. On any convenient part of the bent pipe, is fitted a cock, by closing which, the connection of the cup with the boiler is shut off, and another disc may then be replaced without stopping the operation of the engines. The second improvement consists in the application of a steam whistle, to give notice when the surface of the water in the boiler is below a certain point. The whistle is of the ordinary kind, and the aperture by which it communicates with the boiler is closed by a stem, at the lower part of which is a float, composed of cork, or some light wood, and covered with copper. When the water gets oo low, the float and stem descend with it, and the aperture being thus un- t opped, the steam rushes out through the whistle, and gives notice of the e ficiency.—*Inventor's Advocate.* [Many years since a plan was adopted f having a disc or plate of copper or other metal attached to some part of a boiler, which was made weaker than the boiler, so that if there should be too great a pressure on the boiler, this disc would rend asunder and permit the escape of the steam, and, in some cases, allow the water within the boiler to flow on to the fire and extinguish it. With regard to the second improvement—a steam whistle has been adopted some time past in this country, and a plan very similar to the one described above, was adoptedby Messrs. Maudslays and Field, for the engines, at the water works at Brentford.—See Journal, vol. I., page 375. Ed. C. E. and A. Journal.]

Electro-magnetic Engines.—A new galvanic battery, called the mechanico-chemical battery, has lately been invented by Mr. A Smee, of the Bank of England, which promises to supersede the other forms now in use. Its principle is simple, as its power depends entirely upon finely divided platinum, deposited by means of a simple galvanic arrangement upon any other metal which is unacted upon by dilute sulphuric acid, the only fluid used. At present he finds that silver or plated copper answers admirably for the reception of the platinum, but iron, when platinized, has the same power for a time as these metals, though the iron becomes gradually dissolved. He also finds that with his battery porous tubes can, in most cases, be dispensed with, and that the battery can be advantageously made in any of the various forms hitherto employed. Its effects are more powerful than those of the sulphate of copper batteries, and in action it is less expensive. The practical application of galvanic batteries, except as an instrument of research in the laboratory of the student, is principally confined to the explosion of powder under water, or in other mining operations, for which purposes it appears useful, from its being small in compass, and requiring scarce any manipulation. Whether it may ever be used for locomotive purposes, still remains doubtful, but who knows whether in future ages electro-magnetic engines may not take the place of steam-engines.—*Atlas.*

On a simple mode of obtaining, from a common Argand Lamp, a greatly increased quantity of Light, by Sir J. F. Herschel.—The following simple, easy, and unexpensive mode of greatly increasing the quantity of light yielded by a common Argand burner, has been used by me for some years, and is adapted to the lamp by which I write, to my greatly-increased comfort. It consists in merely elevating the glass chimney so much above the usual level at which it stands in the burners in ordinary use, that its *lower* edge shall clear the *upper* edge of the circular wick by a space equal to about the fourth part of the exterior diameter of the wick itself. This may be done to any lamp of the kind, at a cost of about sixpence, by merely adapting to the frame which supports the chimney four pretty stiff steel wires, but in such a manner as to form four long upright hooks, in which the lower end of the chimney rests; or, still better, if the lamp be so originally constructed as to sustain the chimney at the required elevation without much addition, by thin laminæ of brass or iron, having their planes directed to the axis of the wick. The proper elevation is best determined by trial; and as the limits within which it is confined are very narrow, it would be best secured by a screw motion applied to the socket on which the laminæ above mentioned are fixed, by which they and the chimney may be elevated or depressed at pleasure, without at the same time raising or lowering the wick. Approximately it may be done in an instant, and the experiment is not a little striking and instructive. Take a common Argand lamp, and alternately raise and depress the chimney vertically from the level where it usually rests, to about as far above the wick, with a moderately quick but steady motion. It will be immediately perceived that a vast difference in the amount of light subsists in the different positions of the chimney, but that a very marked and sudden *maximum* occurs at or near the elevation designated in the commencement; so marked, indeed, as almost to have the effect of a flash if the motion be quick, or a sudden blaze as if the wick-screw had been raised a turn. The flame contracts somewhat in diameter, lengthens, ceases to give off smoke, and attains a dazzling intensity. With this great increase of light, there is certainly not a corresponding increased consumption of oil: at least the servant who trims my lamp reports that a lamp so fitted consumes very little, if any, more oil than one exactly similar on the common plan.—*Phil. Mag.*

Steam Boilers.—At the last sitting of the Society for the Encouragement of National Industry, and on the report of M. Séguier the younger, a gold medal was decreed to the elder M. Chaussenot, for an apparatus to render the explosion of steam-boilers impossible. According to the report, his invention is perfect, both as regards its improvements on the safety-valve, and an ingenious contrivance to give notice to the crew and passengers of impending danger. Even the contingency of wilful mischief is provided against; as in the event of all the warnings of his machinery failing, or being disregarded, the steam flows back upon the furnace, extinguishes the fire, and destroys all possibility of an explosion.

Turning Lathes.—At an ordinary meeting of the Society of Arts, the large silver medal was awarded to Mr. J. Hick, jun., of Bolton, for an improved expanding mandrel for turning-lathes. It is necessary that a mandrel should fit so accurately, as to bite on the inner surface with a force sufficient to counteract that of the tool, and, in the ordinary mode, the same ma drel cannot be used for two pieces which are of different diameters. Consequently, in many engineering establishments, a stock of mandrels is kept, amounting to 600 or 700. Mr. Hick purposes to do the same work with eight sizes of the mandril, from one inch and a quarter to ten inches. He effects his object by having the spindle of the mandril shaped on the frustrum of a cone, on the face of which are four dove-tail grooves to receive wedges, the under faces of which have the reverse inclination of the cone, so that the lines of their outside faces are always parallel with the axis of the mandrel. A nut is screwed on the spindle, which acts on the wedges through the medium of a conical cup, which drives them up to their bearings inside of the work.

The Retarder.—Full trial has now been made of this valuable invention of R. W. Jearrad, Jun., Esq., for retarding (not locking) the wheels of carriages when going down hill. Mr. Dangerfield, coach proprietor, having had it applied first to one of his Southampton coaches, and afterwards to the Shrewsbury coach, and in both cases with the greatest success. The principle of the invention is pressure so applied to the nave of the wheel as to retard its motion, or at the will of the coachman stop it altogether. The advantages of the invention are, that the power may be applied at the discretion of the coachman, so that he might take his coach down a steep hill, without allowing his horses to be pressed upon at all. This invention reflects great credit upon Mr. Jearrad, and we hope it will be extensively applied to our four wheeled carriages, for it will contribute materially to the safety of the public.—*Cheltenham Journal.*

Porcelain Letters.—A patent has lately been taken out for an invention to supersede the ordinary wooden letters usually fixed upon the facia of shop-windows. The new letters are made of porcelain, of every form and hue, and when fixed up, present a beautiful and attractive appearance. The facility of cleansing them is not the least of their qualifications; for with a sponge they are immediately brought to their pristine beauty and elegance. It is stated that they will not exceed the old wooden letters in price. Some of the patterns are very elegant, particularly the golden ones, and, being glazed, present a dazzling and animated appearance. They are not quite ready for public use, but it is expected they will soon arrive from the manufactory in Staffordshire.

New Fuel.—The Rev. Mr. Cobbold has invented a fuel composed of peat and the common refuse of gas tar, which burns with a bright flame, little or no smoke, and gives out an intense heat. It has no smell whatever, and has been tried in a grate, in comparison with coal. According to this experiment, which was made by a chemist, but without weighing the fuel, two quarts of water were evaporated in 35 minutes, leaving a good fire afterwards; while with Newcastle coal it took 51 minutes, leaving a low, burnt-out fire. Mr. Cobbold says he can render this fuel at 7s. per ton.—*Railway Magazine.*

A New and Effectual Method to Kyanise Timber.—Within the last two or three weeks the Manchester and Birmingham Railway Company have commenced Kyanising their wood sleepers in a much more quick and effectual manner than by the old mode of simply depositing the timber immersed in the prepared liquid. The company have had made a large iron cylindrical vessel, weighing about ten tons, and which is about thirty feet long, and six or seven feet diameter, made from wrought-iron plates, five-eighths thick, and double rivetted, which vessel is capable of resisting a pressure of 250 lbs. on the inch. The vessel being filled as compactly as possible with wood sleepers, twelve inches broad and seven inches thick, the liquid is then forced in with one of Bramah's hydraulic pumps, and worked by six men to a pressure of 170 lbs. on the inch. By this means the timber is completely saturated throughout in about ten hours, which operation, on the old system, took some months to effect.

Extraordinary Manner of Manufacturing Cloth.—A gentleman, residing at present in London, has just obtained, we are told, a patent for making the finest cloth for gentlemen's coats, &c., without spinning, weaving, or indeed without the aid of any machinery similar to those processes, and at a cost less than one-fourth the present price. The most extraordinary circumstance in this contrivance is, that air is the only power used in the manufacture of the article. The ingenious inventor places in an air-tight chamber a quantity of flocculent particles of wool, which by means of a species of winnowing-wheel are kept floating equally throughout the atmosphere contained therein; on one side of the chamber is a net work of metal of the finest manufacture, which communicates with a chamber from which the air can be abstracted by means of an exhausting syringe, commonly called an air pump, and on the communication between the chambers being opened the air rushes with extreme vehemence to supply the partial vacuum in the exhausted chamber, carrying the wholly floccula against the netting, and so interlacing the fibres, that a cloth of a beautiful fabric and close texture is instantaneously made. Several of the specimens of this cloth that have been shown to scientific gentlemen and manufacturers have excited great admiration. This cloth is a species of felt, but instead of adopting the old laborious method, the above, which is denominated the pneumatic process, is used, and produces the result as it were by magic.—*Observer.*

ON THE CONSTRUCTION OF LIME KILNS.

BY SIR C. S. STUART MENTEATH, BART.

Having been engaged in burning lime for the supply of an extensive district of country for agricultural improvements, and being distant from coal 16 miles, it was desirable to find out the best constructed kiln for burning lime with the smallest quantity of coal, and having been aware from experiment that the kilns generally employed in Great Britain for burning lime are of a construction too narrow at bottom, and too wide at top many kilns of this construction being not more than three or four feet wide at bottom, and 18 feet wide at the height of 21 feet, were found to waste the fuel during the process of calcining the lime, or in other words, did not produce more than two measures of burnt lime shells for one measure of coal; but it is to be understood, that in whatever construction of kiln lime is burnt, the fuel required to burn limestone must vary according to the softness, or hardness, or density of the stone, and the quality or strength of the coal used. The same measure of coal in Scotland called chews, when employed, will burn a greater quantity of lime in a given time than the same quantity or weight of small coal, the chews or small pieces of coal admitting the air to circulate more freely through the kiln. Though this fact should be well known to lime-burners, yet they frequently employ small coal in burning lime, from its being procured at a less price, though really at a greater expense, as it requires a much larger quantity to produce the same effect, and a longer time to admit of equal quantities of lime being drawn out of the same kiln in a given time.

For a sale of lime for agricultural purposes in a limited district, I have found kilns of small dimensions to be most profitable; the construction of a kiln I have employed for many years was of an oval shape, five feet wide at bottom, widening gradually to six feet at the height of 18 feet, and continuing at that width to 28 feet high from the bottom. A kiln of this construction has been found to burn lime in much less time, and with a smaller proportion of fuel, than kilns of large dimensions, narrow at bottom and wide at top, as heat is well known to ascend more rapidly in a perpendicular than in a sloping direction, from which arises the superiority of a narrow kiln, with sides nearly perpendicular, compared with one with sides that slope rapidly.

Those narrow kilns will admit of being drawn out of them every day, if fully employed, more than two-thirds or nearly three-fourths of what they contain, of well burnt lime, and afford fully three of lime-shells for one measure of coal, when large circular kilns will not give out more than one half of their contents every day, and require nearly one of coal for every two measures of lime burnt. In a country sale of lime, the quantity sold every day is liable to great fluctuations; two or three cart loads will sometimes only be required from an establishment which, the day before, supplied forty; and as lime is known to be a commodity, when exposed to the action of air, which becomes more bulky and heavy, and in that state does not admit of being carried to a distance without additional labour, it has been an object of importance with me to find out a construction of a kiln which will allow of lime being kept for several days without slacking, and at the same time to prevent the fire escaping at the top of the kiln, if the kiln stands 24 hours without being employed, especially during the autumn and winter when the air is cold and the nights long. I now employ kilns of an egg shape, and also oval; the oval-shaped kilns are divided by arches across the kiln, descending four feet from the top, the object of the arches across the kiln is to prevent the sides of the kiln falling in or contracting, and also to enable you to form circular openings for feeding in the stone and coal at the mouth of the kiln; upon this plan, a kiln of any length might be constructed with numerous round mouths. From the great expense attending the driving of fuel from a distance of 25 miles from my own coal-pits, I have adopted the practice of cokeing the coal, which is a saving of two-fifths of the weight, and I find that an equal measure of coal and coke have the same quantity of heat in burning lime, which is somewhat paradoxical, but not the less true. The coal is found to have little effect upon the stone till it is deprived of its bitumen, or is coked in the kiln; for, during the time the smoke is emitted from the top of a lime kiln, little or no heat is evolved; or, in other words, does not the smoke carry off the heat, which is not given out from the smoke till it is inflamed, which does not take place in the ordinary lime kilns? A kiln in which coke is the fuel employed will yield nearly a third more lime shells in a given time than when coal is the fuel, so that coke may be used occasionally when a greater quantity of lime is required in a certain time than usual, as it is well known to lime burners that the process of burning is done most economically when the kiln is in full action, so as almost constantly to have a column of fire from the bottom to the top of the kiln, with as short intervals as possible in working the kiln.

Having found that limestone is apt to be vitrified during the process of calcination during stormy weather, from the increased circulation of air through the kiln, which adds much to the heat derived from the fuel employed, and which experienced lime-burners would have diminished could they be aware at all times of an occurrence of this kind: from having experience of the bad effects of too great a circulation without properly providing against it, I have reason to believe that by having a power to throw in at pleasure an additional quantity of air into the bottom of a lime kiln, a considerable saving of fuel necessary for the calcination of lime would take place, and another object would be gained, that of cooling the limestone in the bottom of the kiln, which frequently retards the drawing out of the burnt limestone for some hours, or until the limestone is so cold as not to burn the wooden structure of carts.

In working a kiln with narrow circular mouths, the stone and coal should be carefully measured, so that the workmen can proportion the fuel employed to the quantity of stones, and it is obvious, that the quantity of coal to be used must depend upon its relative quality, and the hardness of the stone to be burnt. If this measure was adopted in kilns of any construction, the lime shells would be found better burnt.—*The Dublin Advertiser.*

STEAM NAVIGATION.

The President Steam Ship.—This vessel, the largest ever yet built, arrived here a few days ago under the command of Captain Kean, and is now lying in Sloyne. She is an exceedingly beautiful model; built of the best material that England and England's wealth can supply, and is in every respect a noble vessel. She is now, (her engines not being yet on board,) what is in nautical term, called "light"; and looms very large. Her proportions are, however, such but for the comparative size of the Queen's mail ships near her, she is so compact that she does not appear at even a short distance to be larger than the "Liverpool." A nearer approach, however, undeceives the beholder, and a visit on board, realizes to its fullest extent the conception of "a wooden world."

She is painted in man-of-war style, with gun ports, and is handsomely rigged as a three-masted schooner, with a foremast, foretopmast, and topgallantmast, approximating to those of a ship. Her bow is fine, and at the extremity of her headrails will be placed, when completed as a figure-head, a bust of Washington, the hero of American independence. Her stern is projective, beautifully formed to turn off a heavy sea; ornamented aloft with the arms of England and America, quartered in heraldic shield, supported by "the Lion of England," and "Eagle of America." The paddle boxes are comparatively very slightly raised above her bulwarks; and her general appearance is, when her side is viewed, that of a first class frigate of extraordinary size, her light rigging given her at the same time a most rakish and mischievous appearance.

The following are the dimensions:—

	Feet.	In.
Length over all, from taffrail to figure-head......	273	0

Breadth from outside of paddle boxes............	72	4
Depth of hold	30	0
Height between the main and spar deck	8	6
Height between lower and main deck (both flush)	7	8

Tonnage supposed 2500.

Those who are versed in maritime affairs will readily conceive from these dimensions that we are warranted in stating that the President, is in reality, "a wooden world." She is indeed, more—she is a world not only of wood, but of iron, copper, and other materials, constituting the *ne plus ultra* of strength in naval architecture.

The President was built at Limehouse, London, by Messrs. Curling and Carter, the latter gentleman superintending her construction throughout. Between decks and in her holds she presents a perfect picture of strength; and we cannot more highly compliment our metropolitan friends and contemporaries in Translantic Steam Navigation, than by stating that they seem in materials, in fastenings, and in putting together, to have taken a leaf out of the book of our townsmen Messrs. Wilson and Co., whose vessels both in point of strength and sailing have hitherto borne the bell.

Every available modern improvement has been taken advantage of in the construction of the President. In addition to a remarkably strong frame, solid to the bilge, she is diagonally fastened fore and aft with iron and wood, in a manner that would seem to defy the rudest assaults of the ocean wave. We have not time to enter into details. Suffice it to say, that the materials of the *President* throughout are of the best quality, and that the utmost science, in a scientific age, has been exerted to work them to the best advantage.

The engines for this vessel will be of about 600 horse power. They are already built by our townsmen Messrs. Fawcett and Co., and present a splendid specimen of the ingenuity and enterprise of the age.

The *President* will present peculiar advantages for passengers. Her spar-deck will afford a long and delightful promenade in fine weather, and during rain or storms a dry and sheltered walk may be enjoyed below.

The cabins are not yet fitted up. The principal or stern saloon will be eighty-seven feet in length; its breadth (including the small state rooms on each side) forty-one feet.

No expense has been spared to render the *President* a crack ship. In strength of materials and fidelity of workmanship, she is fully equal to any of her Majesty's ships of war; and is fitted up with all the modern improvements in pumps, tanks, &c. She is also divided into sections, so that the springing of a leak (should such take place) would be attended with comparatively trifling danger. It is calculated that the *President* will carry 1,000 tons of goods beyond her compliment of coals, luggage, and materials for a trans-Atlantic voyage. Her steering tackle is of novel and improved construction; and such was required; for, from her length and size, she may be deemed a floating island.

The agents of the *President* at this port, are Mr. Pim, of the St. George's Steam-packet Company, and Mr. Macgregor Laird, brother of Mr. Laird, of North Birkenhead, the celebrated builder of iron ships.—*Liverpool Courier.*

The Sons of the Thames.—This vessel which we noticed in the last January number is now fairly before the public, and fully sustains the speed we then announced; she eclipses all the Gravesend steamers.

Steam-Packets to the West Indies.—The directors of the Royal Mail Steam-Packet Company have, with laudable promptitude, contracted for the building and machinery for the requisite number of steamers. Three are to be of 1250 tons burden, and are in regard to the form and the cabins, of a superior construction. They will be ready for sea in the autumn of next year, when our splendid colonies in the West Indies will be brought practically as near to us as were, not long ago, many parts of the United Kingdom to the metropolis. It would be difficult to exaggerate the beneficial effects which may flow from this change, but we shall not dilate on the subject at present. Many of our readers are aware that some controversy has arisen about the route that ought to be adopted with a view to the convenience of all the interests concerned, and it is doubtless a question which deserves full consideration. We understand the Government has the power of altering the course of the packets as circumstances may render expedient.—*Colonial Gazette.*

Steam Mail Packets.—Government having ordered a weekly mail to be conveyed by steam from Hull to Christiansand and Gottenburgh, a contract for the transit has been taken by Messrs. Wilson, Hudson, and Co., of this port, and by whom two competent steam-vessels, of the first class, will be immediately placed on the station. The service is to commence on the 2d of next month. The passage which will be imperatively undertaken at specific hours, to and from the Eastern ports, will afford a safe and certain conveyance, and thereby give an additional impetus to commercial enterprise.—*Hull Times.*

British Queen.—This noble vessel arrived at Portsmouth, on Thursday morning, 16th ult., in 14 days from New York.

The "Lee" Iron Steam Barge has been fitted with Halls patent reefing paddles, and at the beginning of last month made several trips on the Thames, off Greenwich, to show the action of reefing the paddles, both when the barge was laden and unladen. The action is very simple, in outward appearance the paddle wheel being similar to the common one,—although upon inspection it will be found very different. On the shaft of the wheel is a large iron disc about 2 ft. 6 in. radius, composed of two plates of metal; the inside face of one of them, contains a spiral groove, in which plugs are accurately fitted, and fixed to the inner end of sliding arms of iron. These arms are attached at the other or outer end to the float boards, when it is necessary to contract the size of the wheel; the disc is turned round by the aid of a winch, and as it turns round, the plugs fitted to the spiral are gradually drawn up, as the radius of the spiral groove gets smaller; and when it is requisite to enlarge the diameter, the disc is turned in the opposite direction, by this means the plugs attached to the moveable iron arm are gradually drawn into the spiral groove of a larger radius and fores out the float boards. By this simple contrivance, the wheels of the "Lee" can be contracted from a large diameter to a small diameter. For such a vessel as the "Lee" it is highly valuable, as she is to be engaged by the spirited proprietor, Mr. Lee, the extensive lime burner and brick maker, to convey lime from his works up the Medway to London, and occasionally to be employed as a tow boat for bringing up the other vessels when the wind sets directly against them, sometimes this is his case for several days, and we have known instances of London being almost without a yard of lime. We have no doubt this spirited effort of Mr. Lee will cause several iron barges to appear on the Thames before many months have passed over. The "Lee" is an iron vessel built by Messrs. Ditchburn and Mair, and furnished with two oscillating engines by Messrs. Penn and Son of Greenwich:—the various experiments proved very satisfactory.

ENGINEERING WORKS.

WESTMINSTER BRIDGE.

In a former number (23), we described briefly the construction of this interesting bridge, and the works that had been carried on for many years by the late Mr. Telford for protecting its foundations, rendered insecure by the removal of old London bridge. We also explained the extent of improvements contemplated by the commissioners, and the manner in which they were being executed by Mr. Cubitt, contractor, under the direction of Messrs. Walker and Burges.

We have now the gratification of recording the rapid progress of the works, and of congratulating the public on the immense advantages they are likely to derive from the enlightened views of the Commissioners, who in addition to the extensive improvements referred to, have decided on widening the roadway 12 feet, thus making it equal in width to London bridge. The two piers that were inclosed in the dam have been extended for that purpose, and five courses of the soffit of the arch on each side already completed. The difficulty of executing this work can be appreciated only by those who are acquainted with the construction of the foundations on caissons, and a description of the method adopted must be interesting.

By referring to the plan and section in the number alluded to, it will be seen that the intention then was to carry the sheet piling completely round the pier, at a short distance from the caisson to prevent the condensed ground disturbing the framework, afterwards to fill up this space and the openings in the grating with brick, and thus form a solid bed for the Roche Portland pavement. This was done as far as the angles of the south cutwater—the part of the caisson at that extremity was then partially removed, and bearing piles of beech, 10 feet long by 9 inches diameter, driven 3 feet apart over the space on which the extended pier and cutwater were to be erected, and the sheet piling continued round; on the bearing piles were spiked double sills of memel fir crossing over the piles, and of scantlings to bond with the caisson, and form a grating the same height, the openings were filled up with brick, and 6 in. York landings, upon which a course of Roche Portland stone was laid, extending over the whole space, and bevelled off towards the sheet piling, uniform with the pavement surrounding the pier. The Portland stone on each side of the pier was cut out to a depth of 1 ft. 6 in. and 2 feet 6 in., and courses of Bromley fall stone inserted, and carried round on the new foundations; thus the appearance of the piers and soffit of the arch, as high as the top of the fifth course from the springing, is the same as if built at one period. The north cutwaters restored by the late Mr. Telford were not disturbed.

The sluices of the dam were opened on the 13th ult. at high water, the dam having remained quite dry and secure from the time it was closed.

The work both for execution and quality of material cannot be sufficiently admired, and the piers will resist for centuries the attacks of the elements they have to contend with.

The dam round the next two piers is now partly formed, and when the water has been excluded, we promise our readers an account of the sunken pier that excited the greatest interest about 100 years ago.

Wyrley and Birmingham Canals.—About twelve months ago an arrangement was made for consolidating the Wyrley and Essington Canal Company with the Birmingham Canal Company, and we observe that on the 14th ultimo the Act of Parliament for carrying that arrangement into effect received the royal assent. This union will not only be of great advantage to the proprietors, but also to the public, as the united company are going to lay out upwards of £120,000, in making two new lines of canal to connect the Wyrley and Essington canal with the lower level of the Birmingham canal, by one of which the mines in the neighbourhood of Wednesfield and Willenall will be brought into the market; and by the other the lower part of the town of Birmingham may be supplied with coal from the extensive and valuable mines at Brownhills and Cannock Chase. — *Wolverhampton Chronicle.*

Gloucester and Hereford Canal.— About five hundred men are now employed in the continuation of the canal from Ledbury to Hereford. Nearly the whole of the first seven miles is in progress: the works at present are confined to this portion, because the supply of water will be obtained by it, not only for the new part, but also for the sixteen miles from Ledbury to Gloucester: it is therefore anticipated that this additional supply will cause a considerable increase of revenue. The most important works at present under hand are the embankment across the Leadon Valley, at Prior's Court and the deep cutting at Ashberton. The weather has lately been very favourable for the work, and the great progress already made has surprised many persons: part of the line is quite finished, and light boats constructed so as to be easily moved from place to place, are now being used on the finished portion, for the purpose of shifting soil and materials. Patent bricks for facing the locks are being made at Ledbury. The bricks are very superior to any before seen in this country. They are moulded in the usual way, and when in a particular state of dryness they are forced by a heavy weight into the metal mould, which operation not only brings the brick into a perfectly true and square shape, with a fine smooth surface, but also condenses the clay, thereby making the brick stronger and more durable.—*Hereford Times.*

Nelson Memorial.—On the 2d ult., the following tenders were presented and opened by the Nelson Testimonial Committee, held at the National Gallery, for the erection of Mr. Railton's column in Trafalgar-square; Messrs. Grissell and Peto, the builders, being the successful candidates.

Messrs. Grissell and Peto	£17,860
Messrs. Baker and Son	17,940
Mr. Jackson	18,200
Mr. Grundy	19,700
Mr. Hicks	20,500
Messrs. Malcott and Son	27,009

Skew Bridge.—Workmen are now actively engaged in the erection of one of the most, perhaps the most extraordinary iron viaducts connected with any railway, either finished or in the course of completion, in Great Britain. The viaduct in question will cross Fairfield-street, better known, perhaps, as Travis-street, Manchester, or the Manchester and Birmingham line of railway. The great mass of substantial masonry against which the six ribs that compose the arch are intended to abut, is surprising to behold; perhaps anything more substantial, or work better executed, cannot be exhibited in the kingdom. The weight of the iron consumed in this viaduct is 540 tons, and is comprised of six ribs, each 128 feet span. The viaduct is also very remarkable for its acute angle, such angle being 24½ degrees; the width of the street being only 16 yards, or 48 feet. The only erection at all approaching to this in the acuteness of its angle is one on the London and Birmingham line, which is 28 deg. So very correct have the masonry and iron works been executed to the plan and specification, that on fitting the last segment of the first rib it was found impossible to introduce a sixpence between the joints—*i. e.* before the screws that connect the two adjoining segments were tightened. In attempting, however, to fix the last segment in the first rib, before referred to, at noon on the previous day, it was found to be fully three-eights of an inch too long, caused, as it was afterwards proved, by expansion, arising from the heat of the sun—for on the following morning, early, and before the sun's rays could have any decided effect on the iron, it was found to fit its destined place with the utmost possible precision.—*Liverpool Chronicle.*

PROGRESS OF RAILWAYS.

LONDON AND BLACKWALL RAILWAY.

[In the first volume of the *Journal*, page 109, are some comments by an "Old Engineer," relative to the proposed working of the above railway—we now have an opportunity of giving the particulars as to how it is intended to work the line, which we select from the report of the engineers, Mr. George Stephenson and Mr. Bidder, read at the last half yearly meeting of the Proprietors of the Company.]

"In consequence of inquiries, which from time to time are made, we feel that some explanation is desirable respecting the mode to be adopted in *working* the railway, and we, therefore, trust, that a few observations to render this clear will not be out of place on the present occasion.

"It is, we presume, generally known, that you intend to establish several intermediate stations between London and Blackwall, although, by the direct course of the railway, the *distance* is little more than three miles and a half. This accommodation could not be afforded on so short a line if worked by locomotive engines, without either doing away with the velocity usually attained on railways, or by having recourse to more lines of rails, which would, of necessity, involve an increase of locomotive power, and add largely both to the permanent and current expenditure. By means, however, of stationary engines, the desirable object of working intermediate stations for the convenience of passengers is easily secured.

"The plan adopted to accomplish this, is as follows:—Assuming that between London and Blackwall there are three stations, A, B, and C respectively, then the trains starting from London, and drawn by the locomotive engines, would consist of at least four carriages; the carriages might be more numerous for every station, but, for the sake of perspicuity in the explanation, we will assume for each one carriage only.

"The foremost carriage will be that destined to go all the way to Blackwall—the second, that to station C—the third, that to station B—and the fourth, that to station A. In the transit to Blackwall, station A is first reached, but previous to arriving at it, the last or fourth carriage is detached from the train, and is stopped opposite that station, whilst the rest of the train is still progressing. The third carriage is detached and stopped in like manner at station B, and so on till the carriage for Blackwall has arrived at its ultimate destination. The engines then cease working, and the rope which has been drawn from London, and is to be the means of reconveying the carriages back, is in a state of rest. While remaining so, the carriages at their respective stations are loaded and attached for their return, so that in due time when the rope is set in motion by the London engines, all the carriages are started simultaneously. The carriage which was last in the train towards Blackwall, thus becomes the first, and is attached to the rope a mile or two nearer London than the most remote carriage; and as they are all attached to the same rope, they obviously travel at the same speed, though at such a distance apart. It then follows that the carriage from station A, arrives first in London and occupies the furthest portion of the depot:—then follows the carriage from station B, and so on until the last carriage from Blackwall has arrived, when the engines again cease working, the carriages being thus left in their proper relative positions for their next transit towards Blackwall.

"To these arrangements the utmost effect will be given by the adoption of the Electric Telegraph of Professor Wheatstone and Mr. Cooke, similar to that which has been for a considerable period in successful action on the Great Western Railway.

"It is expected that the Railway when completed will afford equal facilities for the carriage of goods as of passengers; but its capabilities for the former description will not be fully developed, because until we have the double terminus in London, with the outlet on the one hand to the Dock Warehouses in Fenchurch Street, and on the other to Cooper's Row, adjoining Tower Hill, the conveyance of goods, confined as the discharge of them must be to the limited depot in the Minories, might be calculated to embarrass and interrupt the passenger traffic at that point."

North Midland Railway.—Between Derby and Rotherham (and on to Sheffield by the Sheffield and Rotherham Railway), the principal operation is laying the permanent road. A double line of rails is laid for a considerable distance north and south of Chesterfield; this part of the line will be opened early in May next. The following contracts are all completed, or very nearly so:—The Beighton, twelve miles north of Chesterfield; the Eckington, Whittington, Chesterfield, Northwingfield, and Clay Cross. On the line north of Beighton, and up to Rotherham, the Staveley, Southwingfield, Lodge-hill contracts, and down to Derby, great exertions are being made to have a double line for the opening, and a great portion of this distance is laid. The only earthwork remaining on this part of the line is finishing the sides of some of the large excavations, and completing an embankment at Bull-bridge. The stations will be completed shortly, as most of them are now roofed in.—*Notts paper.*

Sheffield and Manchester Railway.—We understand that this important line of Railway is at length about to be proceeded with in earnest. It is expected that the whole of the distance between Manchester and Glossop will be under contract during the present summer, and we think that if the Directors are supported in their efforts by the Shareholders, and supplied with funds to enable them to press forward the works with energy and spirit, they may succeed in completing and opening to the public that portion of the line in course of the summer of 1841, and thus secure at once a large and profitable traffic between Manchester and the populous manufacturing districts of Ashton, Staly Bridge, Mottram, Glossop, &c., besides that which they will derive by shortening the difficult road journey between Manchester and Sheffield.—*Liverpool Standard.*

Lancaster and Preston Railway.—We understand that the Galgate embankment, which is generally considered the heaviest work on the line, is at length finished. Mr. Locke, the engineer of the line, accompanied by the secretary, and other gentlemen, made a progress throughout the line, a day or two since, and expressed the pleasure they felt at finding the works in so forward a state. No doubt was expressed that the line would be opened for traffic early in the month of June, or indeed even earlier than that if any special occasion existed for the acceleration. Contrary to general report, Mr. Locke found the works at the Preston terminus in a still more forward state than any other parts of the line. The shareholders of the railway are in high spirits at the prospect held out by Mr. Justice Coleridge, of a return of a great portion of the assize business to Lancaster from Manchester and other places east of Liverpool, as promising a material increase to their returns.—*Lancaster Guardian.*

Travelling at the rate of Fifty-six Miles an Hour.—The ten-feet wheels attached to the locomotive engines employed on the Great Western Railway, not being found fully to answer the expectations of the directors, they have altered their plan, and in future, wheels of seven feet diameter only are to be employed. The result has been the attainment of the speed of fifty-six miles an hour. On Saturday the 28th March, the Fire Fly, a new engine on this principle, manufactured by Messrs. Jones and Company, of the Viaduct Foundry, at Newton, made an experimental trip from Paddington to Reading, and the following is a correct statement of her performance:—She left the station at Paddington at 13 minutes and 18 seconds past 11, A.M., and reached Reading at 59 minutes 43 seconds past 11, having past the first mile post at 11 hours 15 minutes and 57 seconds, and the thirty-fifth at 11 hours 58 minutes and 44 seconds, which is equivalent to one mile in one minute and 15½ seconds, or nearly 48 miles an hour. During the journey one of the tender springs broke, and caused some additional friction on the axles. The load was two carriages and one truck. At 3 hours 19 minutes and 9 seconds the party started on their return to London, with two carriages. They stopped to take in water at Twyford, which detained them 14 minutes and 44 seconds, and finally arrived at Paddington at 21 minutes and 3 seconds past four o'clock. The twenty-ninth mile post from London was passed at 3 hours 44 minutes and 50 seconds, and the second at 5 hours 16 minutes and 51 seconds, which is equal to the speed of 1 mile in one minute and 11⅝ seconds, or an average 50½ per hour. The greatest speed attained was from the 26th to the 24th mile post, which was done at the rate of 56 miles an hour. This is the greatest speed at present attained in the history of locomotive power—what will ultimately be the greatest, it is impossible to foretell. Messrs. Jones and Co. have since forwarded a second engine from their works to London, and they have four others in process of erection for the use of the Great Western Railway Company.—*Manchester Courier.*

Midland Counties' Railway.—The works on this line as far as Leicester are in an extreme state of forwardness, and there is not the slightest doubt the first week in May will see the train flying over the high embankment, or through the deep cuttings, to that place. From Long Eaton to Sutton Bonnington, two lines of rails are completed—the splendid bridge over the Trent being now crossed by engines and trains of waggons, and the tunnel being also quite passable. At Sutton Bonnington there is a deep cutting beside the church-yard, and a station is building, which will require some little work, but the number of hands employed will soon complete that. Past Normanton-on-Soar and Loughborough all is finished, the station at the latter place being a very large one; but at Barrow-upon-Soar there still remains considerable cutting to be done, one place being cut down to 50 or 60 feet and not being yet completed. At Cossington there is a little work, but at Sileby this is counterbalanced by there being a total completion, comprising several very high bridges, which support the line above the village streets, and also some exceedingly deep cuttings. At Syston, the bridges and station are also nearly finished, the latter being only one story high, but still very compact, and containing plenty of room. At Thurmaston, about a mile and a half from Leicester, a piece of embankment is yet to be laid, and about a mile from Leicester there is some embankment required, but near to Leicester the works are in an extreme state of forwardness. The station is a noble one; the front facing the street is supported by five huge iron pillars. The engine house, depot for carriages, workshops for engineers, &c., are on a most extensive scale.—The bridges across the railway at Leicester, viz., across the Humberstone-road, London-road, &c. are finished, but at the top of New Walk, a tunnel is being built which will require some time to complete. About a mile and a half past Leicester, a very fine viaduct is in course of erection; and at Rugby another viaduct, not equalled by any in the kingdom for workmanship, is finished. In short, on the whole, the line may be fairly said to have sprung into being, so quick has been its progress. A new plan has been adopted at Leicester in building the bridges, viz., to build the side walls so high as to prevent any one looking over, and thus at the same time protecting numbers from accidents. The process of blasting is much practised at Leicester. In conclusion, we are sorry to add, that within the last fortnight two men have been killed on the works at separate times. A horse was also killed on Tuesday morning week, by falling down an embankment. The Directors intend giving a grand opening day when the trains run to the Rugby station for the first time.—*Notts Review.*

Edinburgh and Glasgow Railway.—This line of railway is getting on rapidly, and the tunnel in Bell's Park is getting forward at a quick rate. There are three steam engines employed at this tunnel bringing up the stones and rubbish at three holes, technically called "eyes," and a great quantity of stuff is brought up in the course of a day.—*Glasgow Chronicle.*

Great Western Railway.—This line was opened on Monday, March 30, for public traffic as far as Reading; and the day being unusually fine, attracted a large concourse of people there to witness the arrival of and department of the trains. The Company appear to have made the arrangements at this station conducive to the comfort of the passengers, as well as to the facility of carrying on a very considerable traffic in that important town. On Saturday last the Directors went down for the purpose of finally inspected the station and line, previously to their being opened to the public. The train, consisting of two carriages, and a truck, with about forty persons, left Paddington at eleven o'clock with the *Fire-Fly* engine, and reached Reading, a distance of 35½ miles, in 45 minutes, being at the rate of 47½ miles per hour. On their return with the same engine and train, after stopping at Twyford for water, they travelled the whole distance of 30¾ miles, from that station to Paddington, in 37 minutes, being an average speed of 50 miles per hour. The maximum speed obtained was at the rate of 58 miles per hour.—*Daily papers.*

South Eastern and Dover Railway.—A report has been industriously circulated by a cotemporary that a great number of men have been discharged from the tunnel works of this railway in our neighbourhood, which is calculated to create a suspicion that the company is in difficulties. We are happy, however, to be enabled to find, on the most minute inquiry, that such a presumption is entirely void of foundation. It is true that a few bricklayers have been discharged, owing to a limited supply of bricks on the part of the contractor; but at the same time, nearly 200 additional workmen have been set on at the contracts extending from Abbot's Cliff to Folkestone. On a personal inspection we find the work in a most promising condition. The Shakspeare tunnel will, we doubt not, be completed by the end of May. A large portion of the sea wall is nearly finished, and the Warren contracts are proceeding as well as the nature of the ground will permit.—*Dover Chronicle.*

NEW CHURCHES, &c.

Staffordshire.—The foundation stone of a new Church on the estate of Earl Talbot, at Salt, near Stafford, was laid on Thursday, March 26th, by his Lordship's daughter, the Marchioness of Lothian. The edifice will be built of stone in the Gothic style, and will accommodate about 250 persons.

Birmingham.—On Tuesday, March 31, the foundation stone of the new church of St. Mark, being the second of the ten churches proposed to be erected in Birmingham, was laid by James Taylor, Esq., in the presence of a large and respectable body of spectators. The spot chosen for the edifice is a beautiful and commanding site near the Sandpits gate. Messrs. Scott and Moffatt, of London, are the architects; and Mr. C. J. Brailsford, late of Huddersfield, is the builder; Mr. G. David, of Lichfield, being appointed clerk of the works. The church will be built entirely of stone, obtained from the quarries of J. F. Ledsam, Esq., of Weoley Castle, and will contain one thousand sittings, one-third of which will be free. It will be erected in the early English style of architecture, and though the moderate sum for which the contract is taken (£3,000,) will not admit of much costly decoration, the edifice will present, when finished, a very chaste and elegant appearance; and the committee have every confidence that the work will be completed in a substantial and satisfactory manner. The church will, we understand, be finished by the 1st of May, 1841.—*Midland Counties Herald.*

New Episcopal Chapel at Camborne.—On Tuesday the 10th March, the foundation stone of this building was laid by the Venerable Archdeacon Sheepshanks. The chapel, (designed by, and being built, under the superintendence of Mr. Wightwick,) is in the Early Pointed style, exhibiting, in no stinted degree that appropriately ornate character which should distinguish every building of its class. Indeed we understand it was to this end that Mr. Pendarves increased his subscription from £300 to £500. The building is intended to accommodate about 330 persons, of whom not less than 200 have their sittings free. The total length of the interior, (including the chancel and choir projections at the east and west ends) is about 82 feet: the width of the main chapel 30 feet; and its height 31 feet. The interior will derive its chief effect from the exhibition of the timbers of its ornamental roof, and the lofty arches opening before the triple windows of the chancel and choir. The approved success of this fashion in the chapel at Bude Haven, erected some years back by the same architect, has induced him to repeat it in the present instance. The chapel is expected to be completed in eighteen months from the present time.—*Plymouth Herald.*

Rome.—The Viceroy of Egypt has offered to the Pope four magnificent columns, each upwards of 13 feet in height, cut from a quarry of alabaster, discovered a few years ago. They are intended to adorn the new church of Saint Paul at Rome. This splendid present has been accepted by his Holiness, and is to be conveyed to Rome at his expense.

PUBLIC BUILDINGS, &c.

Cornwall.—The new Market Houses at Bodmin, Cornwall, are fast approaching towards completion. This building will form a most conspicuous improvement to the main street of the town, as it is erected upon a site of land formerly occupied by several ruinous tenements with projecting pent houses. The front is built of granite, the centre part or entrance being formed by four massive pillars in single blocks, with architraves over, 14 feet long each, weighing nine tons each; indeed, this front may be likened unto Stonehenge, as, with the exception of the ashlar and cornice, it may be said to consist of 13 massive blocks. In the architrave over the pillars are sculptured oxen heads, taken from the antiquities of Delos. The shamble fittings are to be iron, and the front enclosed with three pair of handsome iron gates. The cost of the erection will be about £3000. William Harris, Esq., of Bristol, is the architect.

Cornwall.—The new Town Hall at Helstone was opened for public business on the 14th of April, by the Recorder. This erection is in the Grecian Doric style, and cased entirely with Constantine granite: the front is composed of a basement having three entrances, viz., two to the corn markets, which are under the Guildhall, and one to the Guildhall. Above the basement are fluted granite Doric columns and pilasters, with entablature over and sculptured pediment, consisting of a clock in the centre, the band of which is composed of oak leaves and acorn-wreaths, and upon each side, forming supports, figures of St. Michael and the Dragon, being the town arms, which have been ably pourtrayed by Mr. Thos. Tyley, Sculptor, Bristol. The new General Market Houses in this town are now quite completed, and, together with the Town Hall and Corn Markets, reflect great credit upon the architect, William Harris, Esq., of Bristol. The cost of the Market Houses and Town Hall, including all expences, £6000.

MISCELLANEA.

Burning Coal Mines.—Letters and papers from the department of the Allier, bring accounts of a remarkable conflagration which broke out in the coal mines of Commentry, on Sunday the 15th March, and had been burning for a week with daily increasing fury. It appears that this fire, which, for the last four and twenty years, has been silently smouldering in the bowels of the earth—revealing its existence by perpetual smoke, and occasional outbreaks of flame, which, however, had always been confined within the limits abandoned to its dominion—had, at length, made its way through some breach into one of the vast galleries of these extensive workings; and there, meeting with the air-current so long denied it, had spread through all the subterranean chambers and passages with a rapidity before which resistance became utterly powerless; showing itself at every crevice and outlet of the vast labyrinth, and flinging its points and columns of fire far up into the air, through all the shafts that led into the wide field of the rich deposit. Luckily the solemnities of the day had emptied the workings of their human tenants, for no mortal aid could have availed them against the suddenness with which the fiery flood swept over all things. The authorities of the district were early on the spot, but have hitherto been little more than idle and awe struck spectators. Neither Vesuvius, nor any other irruption, say the accounts, can give a notion of the dreadful and sublime scene. "If," says one writer, "it were possible to forget that the flames have been, three whole days, devouring immense wealth, and that by this confirgration three hundred fathers of families will be thrown out of employment, there would be room for no other sentiment than that of admiration at the magnificent spectacle. Imagine a deep ravine, nearly circular, in the form of a reversed cone, with its edges, however, hourly enlarging. Through fourteen large openings, issuing at about twenty feet above the ground of this ravine, and giving access to the innumerable galleries of the mines below, as many torrents of flame are poured forth, with frightful violence from the cauldrons within—flames of a thousand hues, rushing forth like fiery whirlwinds—dividing, and crossing, and mingling, and rising, and falling, and rising again! At times, a hollow cracking sound echoes through the abyss; this is some huge block of coal detaching itself from the roof or sides of one of the galleries, and falling into the blazing gulf. Then rises up a thick column of black dust, till it reaches the openings of the galleries, where, pierced in all directions by the flames, long serpents of fire work through its volume from side to side. Sixty feet higher up, on each side of the galleries, two gaping mouths shoot into the air their dazzling columns of fire. Suddenly one of these ceases. It seems for a moment, as if checked in its wrath. Then comes a long and startling groan from the entrails of the earth; and forth again rushes the flame, blood red, roaring and terrible, threatening in its fury to lift up the burning mountain altogether, and bury the spectators beneath its dreadful ruins. Again, look around you; it is midnight, and two thousand human faces are there, some grouped on the opposite crest of the ravine, some sheltered in the cavities of the rocks. Yet no sound meets the ear save that of the roaring flames." The latest accounts states that the rafters of the galleries had all fallen, and the founts of flame nearly ceased to play. The whole had become one huge burning gulf. The loss is said to be incalculable; millions of hectolitres of coal had been consumed. The engineers were preparing to turn the course of a stream, which flows at a league's distance, and direct it upon the burning mountain. Workmen were employed night and day in this operation, by which it was hoped to lay the mines under water.—*Athenæum.*

The Brick Trade.—It has been recently ordered that in estimating the duty, the size of the brick shall be measured in its dry, and not in its moist, state, as hitherto. Those familiar with the manufacture of bricks will at once see the fairness of the regulation, as some clays pine in much more than others.

Model of the Church of St. Peter.—We beg to call the attention of our readers to this most elaborate work of art, which is now exhibiting in the Gallery in Maddox-street, opposite St. George's Church, Hanover-square. It is the work of Celestino Vai, who has had the boldness to come to this country, trusting in the hope that he might reap an abundant harvest, and we most heartily wish him all the success the great merit of his model entitles him to expect. We can truly say, that it gives a more satisfactory idea of the celebrated original—of its beautiful proportions and enormous size—than any painting could possibly do. It is, therefore, a most interesting exhibition, not only to those who have had the good fortune to have seen Rome, but to that class more particularly who are untravelled. It is executed in wood, on the scale of 1 to 100, and consequently takes up a considerable space in a very large room. The fidelity and beauty with which every architectural ornament is rendered, is truly surprising, and this is more particularly evinced in the numerous statues that ornament the building. Every one of these represents a different attitude, and their number, amounting to between 500 and 600, renders them an amusing study. We may here observe, that the artist has represented the building as the architects intended it to be, but, as the church is not yet finished, he has executed a much greater number of figures than are now actually placed on the building. In the centre of the piazza is the Egyptian obelisk, which rises to the height of 131 feet. Its structure of red granite is exactly imitated. The fountains too are there, and the grand flight of steps which leads to the vestibule, and all about are scattered little diminutive figures, which will serve to show the relative size of the building. The colonnades next attract the attention, and although in our opinion they are out of place, yet the fame they have acquired the architect, Cellini, is well deserved. Above all we were attracted by the glorious dome of Michael Angelo, which is indeed a wonder to look upon. This exhibition cost the artist (Vai) a labour of 11 years, to him a labour of love. The room is surrounded by a clever panoramic sketch of the most interesting objects in the immediate vicinity of this most celebrated church.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM 30TH MARCH TO 23RD APRIL, 1840.

Claude Joseph Edmeu Chaodron Junot, of Brewer Street, Golden Square, Operative Chemist, for "*certain improved processes for purifying and also for solidifying tallows, grease, oils, and oleaginous substances.*"—Sealed March 30: six months for enrolment.

Henry Martin, of Morton Terrace, Camden Town, for "*improvements in preparing surfaces of paper.*"—March 30; six months.

William Neale Clay, of Flimby, Cumberland, Gentleman, for "*improvements in the manufacture of iron.*"—March 31; six months.

John Leberecht Steinhaneser, of Upper Islington Terrace, Gentleman, for "*improvements in spinning and doubling wool, cotton, silk, and other fibrous materials.*" Communicated by a foreigner residing abroad.—March 31; six months.

Peter Bancroft, of Liverpool, Merchant, and John Mac Innes, of the same place, Manufacturing Chemist, for "*an improved method of renovating or restoring animal charcoal, after it has been used in certain processes or manufactures to which charcoal is now generally applied, and thereby recovering the properties of such animal charcoal, and rendering it again fit for similar uses.*"—March 31; six months.

Charles Cummins, of Leadenhall Street, Chronometer Maker, for "*certain improvements in barometers and sympiesometers.*"—April 2; six months.

James Stead Crosland, of Leeds, Engineer, "*for certain improvements applicable to locomotive and other steam-engines.*"—April 2; six months.

Thomas Smedley, of Holywell, county of Flint, Gentleman, "*for improvements in the manufacture of tubes, pipes, and cylinders.*"—April 4; six months.

Harrison Blair, of Kearsley, Lancaster, Chemist, and Henry Hough Watson, of Little Bolton, Chemist, "*for an improvement or improvements in the manufacture of sulphuric acid, crystallized soda, and soda ash, and the recovery of a residuum or residuums, applicable to various useful purposes.*" April 6; six months.

Richard Beard, of Egremont Place, New Road, Gentleman, "*for improvements in printing calicoes and other fabrics. Communicated by a foreigner residing abroad.*"—April 6; six months.

Edward Thomas Bainbridge, of Park Place, Saint James', Gentleman, "*for improvements in obtaining power.*"—April 13; six months.

Thomas Young, of Queen Street, in the city of London, Merchant, "*for improvements in lamps.*"—April 13; six months.

James Caldwell, of Mill Place, Commercial Road, Engineer, "*for improvements in cranes, windlasses, and capstans.*"—April 15; six months.

John Gold, of Etna Glass Works, Birmingham, Glass Manufacturer, "*for improvements in the manufacture of decanters and other articles of glass.*"—April 15; six months.

William Potts, of Birmingham, Brass Founder, "*for certain apparatus for suspending pictures and curtains.*"—April 15; six months.

Louis August de St. Sylvain Baron de Los Valles, of Nottingham Street, Mary-le-bone, "*for certain improvements in cleansing, decoticating, purifying, and preserving corn and other grain. Communicated by a foreigner residing abroad.*"—April 15; six months.

William Grimman, of Camden Street, Islington, Modeller, "*for a new mode of wood paving.*"—April 15; six months.

Joseph Whitworth, of Manchester, Engineer, "*for certain improvements in machinery or apparatus for cleaning and repairing roads or ways, and which machinery is also applicable to other purposes.*"—April 15; six months.

Thomas Robinson Williams, of Cheapside, Gentleman, "*far certain improvements in obtaining power from steam and elastic vapours or fluids, and for the means employed in generating such vapours or fluids, and also for using these improvements in conjunction with distillation or evaporation, and other useful purposes.*"—April 15; six months.

William Unsworth, of Derby, Silk Lace Manufacturer, "*for an improved tag for laces.*"—April 16; six months.

Samuel Wilks, of Darleston, Stafford, Iron Founder, "*for improvements in the manufacture of vices.*"—April 16,; six months.

William Henry Bailey Webster, of Ipswich, Surgeon, R. N., "*far improvements in preparing skins and other animal matters for the purpose of tanning, and the manufacture of gelatine.*"—April 16; six months.

Samuel Marlow Banks, of Bilston, Stafford, Gentleman, "*far improvements in the manufacture af iron.*"—April 16; six months.

Robert Cooper, of Petworth, Gloucester, Gentleman, "*for improvements in ploughs.*"—April 16; six months.

Francis Molineux, of Walbrook Buildings, London, Gentleman, "*for improvements in the manufacture of candles, and in the means of consuming tallow and other substances for the purposes of light.*"—April 23; six months.

Elijah Galloway, of Manchester Street, Grays' Inn Road, Engineer, "*for improvements in steam engines, which are also applicable to engines far raising and forcing fluids.*"—April 23; six months.

Jonathan Sparke, of Langley Mills, Northumberland, Agent, "*for certain improved processes or operations far smelting lead ores.*"—April 23; six months.

John White, of Manchester, Engineer, "*far certain improvements in vices.*"—April 23; six months.

James Malcolm Rymer, of Henrietta Street, Civil Engineer, "*for certain improvements in castors for furniture, such improved castors being applicable to other purposes.*"—April 23; six mon ths.

TO CORRESPONDENTS.

The sketch of the gothic window at Clomel Church is received, and will be noticed next month.

We do not consider Mr. Coles' *plan for propelling steam boats on canals is practicable; besides, the outlay required to carry it into execution will be too large to induce any canal company to adopt it.*

"A Subscriber" *is informed that there is a society called* "*The Contractors Association*"; Mr. Barry *of Manchester is the secretary.*

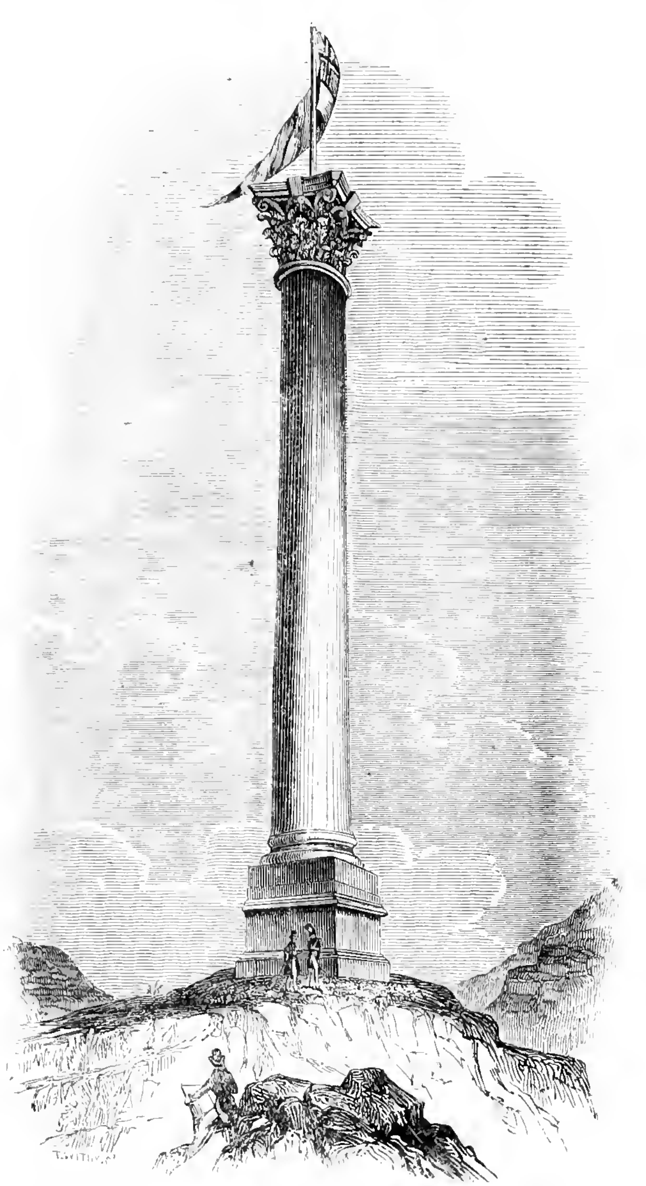
W. J. B.—*We do not think, being admitted inta the Institution named will be of much service to him, until he has had some practice in a respectable office. We regret that we cannot give any advice that will be beneficial to him, for the object he wishes to attain.*

Communications are requested to be addressed to "The Editor of the Civil Engineer and Architect's Journal," *No.* 11, *Parliament Street, Westminster.*

Books for review must be sent early in the month, communications on or before the 20th (if with wood-cuts, earlier), and advertisements on or before the 25th instant.

The First Volume may be had, bound in cloth and lettered in gold, Price 17*s*.

*** The Second Volume may also be had, Price 20*s*.



VIEW OF THE COLUMN NOW ERECTING BY GENERAL BROWNE CLAYTON, ON THE ROCK OF CARRICK A DAGGON, COUNTY OF WEXFORD, IRELAND.

THE column is a fac-simile of Pompey's Pillar, but not monolithic, it is being constructed under the directions of Mr. Cobden the architect, of granite, from the county of Carlow, with a staircase up the centre, the situation upon which it is erected is a considerable eminence above the sea, and when finished will form a conspicuous land mark for mariners. The following are the principal dimensions of the column, height of base 10 ft. 4 in., shaft and base 73 ft. 6½ in., capital 10 ft. 4½ in., total height 94 ft. 3 in., diameter of shaft at the base 8 ft. 11 in., and at the top 7 ft. 8 in.

"This column is to commemorate the conquest of Egypt, and the events of the campaign under the command of Sir Ralph Abercromby, K.B., in the year 1801, when General Browne Clayton, (then Lieut. Colonel), commanded the 12th Light Dragoons, and afterwards commanded the cavalry in pursuit of the enemy to Grand Cairo, taking besides other detachments a convoy in the Lybian Desert, composed of 600 French cavalry, infantry, and artillery, commanded by Colonel Cavalier, together with Buonaparte's celebrated Dromedary corps, one four pounder, and one stand of colours, and capturing 300 horses and dromedaries, and 550 camels.

"The events of this campaign are further to be commemorated, by the appointment of trustees under the will of General Browne Clayton, who shall annually at sun rise on the morning of the 21st of March, (when the French under the command of General Menou, attacked the British encampment before Alexandria), raise the standard on the column, and hoist the tricolour French flag which shall remain until the hour of 10 o'clock, when the British flag shall be hoisted and kept up until sunset, as a memorial of the defeat of the French, which event forms the prelude of Britannia's triumphs through a regular and unbroken series of glory and prosperity down to the battle of Waterloo, in 1815. And on the 28th of March annually, the British flag shall be hoisted half standard high as a memorial of the death of the brave commander-in-chief Sir Ralph Abercromby, who died of the wounds which he received before Alexandria, on the 21st of March 1801."

WYRE LIGHTHOUSE.

*Description and structure of the Wyre (Seaward) Lighthouse, leading to Port Fleetwood.**

IT was my study when planning this navigation to identify the remotest spit of bank turning into it, without subjecting the mariner to the treacherous, and, at best, but partially-lighting agent, a *Light Vessel;* Messrs. Alexander Mitchell and Son, of Belfast, readily took up the proposition, and the Board of Directors of the railway and harbour project, as readily adopted the application of Mitchell's ingenious mooring screw† to the insertion and basing of piles or pillars, in sub-marine foundation. I had given much trouble to Messrs. Mitchell, when unavailingly submitting their plans and specifications to the Liverpool Dock Committee, (Oct. 4, 1838,) of so perfect a mode of establishing lights *out upon the very* banks of a navigation, whereby the power and object of a lighthouse is enhanced by proximity with the anxious observer from sea. In fact, a lighthouse can be thus erected upon any *under-water* spit, as indifferent to a 30-feet rise of tide and channel surge, whilst sending forth its light of the same character and stability, as if on the main land; thereby throwing it more intensely and effectively *on the region required*, especially where shoals out-lie the main to any extent. Its time in erection, the shortest possible,‡ and of so portable a structure that it may be removed, if local changes require, to another site in a month. Wherefore, then, should not every spit, now guarded by a light-vessel, with her unavoidably inferior order of lights, rendered more so in a gale of wind by pitching, floundering about, and ever and anon submerged in the trough of sea, spray, and spoon-drift, and that too when most wanted, and often at the very crisis of exigency to all around, *breaking adrift!* Wherefore not supersede them by so purpose-like a fabric? Let those who take interest, but who doubt or cannot conceive the matter, go to Fleetwood-mount Observatory, commanding the mouth of Wyre, and watch the effects of a westerly gale upon the first of its kind, (not associating the effects of a sea-way upon the Eddystone or Bell Rock, for the screw-piled pillars *do not oppose* the sea). A structure destined to save many a gallant bark that would otherwise drive, unbeaconed and unwarned, upon the sands of Morecambe Bay, and I doubt not will give rise to a general adoption; whilst rendering it imperative on local guardians of a navigation, to establish REFUGES for the cast-away mariner, on the isolated banks; since, by this method, the practicability is manifested. Indeed, this sub-marine method of commanding foundation and *hold-fast*, so ingeniously contrived by Messrs. Mitchell, combines the vital essentials to the seaman's hope, of *warning, guiding, succouring*, and, when in port, *securing!* The figure of this first '*Screw-pile*' Lighthouse in the United Kingdom,—in the world I may say, is shown in the annexed engraving, and presents to the eye a well-proportioned group of columns rising out of the sea, in the intervening and over-lapping order that hexagonal or six-angled figures produce, according to the separate angles you may be opposite to; a systematic interlacing of tension-rods renders the fabric sufficiently opaque, even below the platform; but above the platform, of 27 feet diameter, you have a six-angled dwelling-house of 20 feet diameter, by 9 feet high; on the centre of which rises the 12-sided lantern, with Chinese roof, of 10 feet diameter. Thus, you have a figure of 46 feet spread at the base, contracting at the platform balcony to 27 feet, and elevated 45 above low-water level; surmounted, as stated, by a bulky, yet pleasing and effective, superstructure, comprising a

* We are indebted for this description and drawing to a very able work, by Commander H. M. Denham, R.N., F.R.S., lately published at Liverpool.

† See Journal, Vol. II., p. 38,

‡ The Wyre Lighthouse was reared in two of the shortest-day months in the year, not affording *daylight* during a low-water period, spring tides, but depending on flambeaus or moonlight.

comfortable residence for the light-keepers, whilst affording you a steady, bright, *uniform* light, 45 feet above mean-sea level,—ranging over an eight-mile horizon, visible 10 miles from a coaster's deck, and freed from those *breaks* of brilliancy attending the offing passage from reflector to reflector, by being fitted with a light of '*Dioptric*' order. Foggy periods are provided for by a self-acting deep-sounding bell, tolling three strokes of five-second intervals, at one minute pauses; and tide-time for vessels of 12-feet draft, is denoted by 2 black balls being kept upon its flag-staff until 12-feet ceases upon the *straight course, right up;* at the same time, however, denoting 17 feet up through the *buoyed* channel; and vessels requiring a Wyre pilot will be understood at this lighthouse, if showing a weft at the peak, besides their pilot-jack at the mast-head; whence, a pilot-jack will *also* be hoisted until she is provided. The Wyre pilot-boats are of sloop and yawl rig, with black bottom, *white* top-sides and black streak, with her number and the letter F on the mainsail. Their cruising ground extends from Formby Point to Havering Point of Duddan.

Specification *of the above Screw Pile Lighthouse, erected on the north-eastern low-water spit of North Wharf Bank, at the entrance of the Wyre Navigation, the structure being supported upon, and secured to, the bank with Mitchell's Patent Screw Piles, of 3 feet diameter.*

The foundation of the building is formed of seven screw piles, six of which are the angles of a hexagon, about 46 feet in diameter, and the seventh pile stands in the centre of the figure.

The heads of all the outer piles have an inclination inwards, by which the diameter of the frame-work connecting the top of the columns, and upon which the house stands, is contracted to about 27 feet. Each screw pile is formed of a malleable iron shaft 15 feet long and 5 inches diameter.

On each pile a 3-foot screw is firmly keyed near its lower extremity, beneath which is placed a large drill or opening bit.

At the upper end of the shaft is a screw of 18 inches long and 2 inches diameter, for drawing down and screwing the wooden column to the iron pile, which latter stands about 5 feet out of the ground.

The columns are thus prepared;—seven logs of Baltic timber are selected, of the largest and best quality; the centre one is 56 feet in length, all the others are 46 feet.

The pedestals rise about a third of their height, and the remainder of the shafts are rounded, both for appearance and as lessening any vibration from the action of the sea.

An opening in the lower end of each column is then made of 5 inches diameter, and to the depth of about 8 feet, by boring in the manner of a water-pipe; strong iron hoops are then driven upon it, hot, the first about 8 feet up, the second about 4 feet, and the third at its lower extremity.

This hooping will give to the column greater strength than it originally possessed, especially as the wood removed by boring is the weakest in the tree, and adds scarcely anything to its actual strength.

The column being raised perpendicularly above the iron pile, the end of the latter is introduced into the opening prepared for it, and which has been made to fit accurately upon it; when the top of the pile has reached the end of the cavity, screwing on (by capstan), the foot of the column will be inserted in the bank about 3 feet; the wood, when wet, will clasp firmly on the iron, but, as an additional security, the internal screw attaches the two together.

The framing upon which the house stands is firmly secured round the centre column, and to the heads of the outer ones, by means of cast-iron capitals let down over the heads of the columns, the capitals being cast hollow for the purpose; to the abacus of these the top framing is secured with screw bolts passing down through the wood and iron, having nuts on the under side, all boring or cutting into the main support of the building being thus avoided, and the adjacent parts of the framing are bound together by wrought-iron straps and knees; the beams which radiate from the centre to the heads of the outer columns are 12 inches deep by 7 inches wide, and those which connect the head of the outer columns, 12 inches by 4.

To give lateral strength to the building to resist the effect of heavy bodies drifting against it, twenty-four angle braces from round iron of $1\frac{1}{4}$ inch diameter are applied, as shown in the plan, by which a resisting power equal, at least, to 350 tons, is presented in every direction; these braces are secured at the top to trusses cast with the capitals, and beneath to strong wrought-iron bands with projecting bolt holes; by these means boring into the columns is again avoided, the braces are keyed up at their crossing, as shown in the plan.

The light-keepers' house, which is hexagonal, is in diameter from angle to angle 22 feet, and 9 feet in height.

The centre column rises to the base of the lantern, which, with the roof, it assists to support, giving great additional stability to the whole structure.

The corner-posts of the house are 7 inches by 6, all remaining studs 6 inches by 4, beams of roof 9 inches by 5, and all outside planking, together with floor and roof of house, is 2 inches thick.

The house has an outside door and three windows, and is divided into two apartments, one having a fire-place and the floor tiled; the walls and ceiling of both apartments are lathed and stuccoed.

The lantern, which is 12 sided, is 10 feet in diameter, and in height to the top of the windows 8 feet, by which the lights are raised above the highest spring-tide level about 31 feet, or $44\frac{1}{2}$ above half-tide level.

The lights (in this case of dioptric order) show throughout the periphery, and the roof is covered with strong sheet iron; (a lightening repeller and conductor, of course).

The light-keepers' house is covered with sheet lead, and a light iron railing is carried round the top of the building and the platform.

60, *Pall Mall, London,* HENRY MANGLES DENHAM.
Jan. 31, 1840.

THE UNION BANK OF LONDON.

The Joint-Stock Banks promise like the Assurance Offices to give some employment to architects in the metropolis, as they have already done in the country. Any thing in fact is worthy of encouragement which rises above the mere brickbat and whitewash style. This building situated on the north side of Argyle Place, Regent Street, intended to form the West-end Branch Establishment of the Union Bank of London is nearly completed, from the designs and under the superintendance of Mr. William H. Newnham and Mr. George B. Webb, joint architects to the bank. Tenders for its erection were sent in by public competition last September, when that of Messrs. Turner and Sons, of Little Moorfields, being accepted by the Court of Directors, a contract was entered into with them for building it at the sum of £3860. It occupies a frontage of 70 feet towards Argyle Place, and is three stories in height. It contains on the ground floor, a banking office 28 feet long (exclusive of circular end towards Regent Street) by 20 feet wide, and 16 feet 6 inches high, divided at one end by a screen of Bath stone Doric columns and entablature from a lobby 20 feet by 6 feet, which communicates with the Directors' Committee-room, the Manager's, and the Waiting rooms. On the basement is a groined strong-room, 18 feet by 14 feet, washing-room, &c., for clerks, porter's room, and coal-vaults. The remainder of the house is devoted entirely to the use of the Manager, who will reside on the premises, and comprises, on the first story, which is 13 feet high, a large drawing-room with circular Venetian window, a breakfast parlour, bed-room, and dressing-room, four bed-rooms and store-room on the second floor, with kitchens, wine, coal, and wood cellars, and other requisite accommodation on the basement.

Simple in its character, this building has a solidity of appearance which we trust is appropriate to the institution to which it is devoted, and it cannot fail to prove an ornament to the neighbourhood, and an example to other companies.

Dyeing Timber.—Amongst the subjects lately discussed in the French Academy of Sciences are, a discovery, by a Dr. Bourguet, for dyeing and preserving timber, and one for obtaining blue or red silk from silkworms. Dr. Bourguet states, that if the lower part of the trunk of a tree be immersed, as soon as it is felled, in a preparation of pyroligneous acid, the preparation will be absorbed throughout the whole of the tree, and that the timber will subsequently resist decay. He states, also, that if colouring matter be placed in the liquid, it will be carried through all the vessels of the tree, even to the leaves, and be permanently fixed. As this gentleman has made frequent experiments, there appears to be no doubt of the correctness of his theory. The mode of obtaining blue or red silk from silkworms is kept a secret, except as to an admission that it depends on the food of the insect. M. Flourens, a member of the academy, had previously ascertained that the flesh, and even the bones of animals, may be coloured, by keeping them for a long period on food highly impregnated with colouring matter.

Bendable Stone.—In the Museum of the Asiatic Society at Calcutta, one object of curiosity is a bending or elastic stone. This stone is, apparently, of granite, is about two and a half feet by six inches in length and breadth, and about an inch thick. This stone, being lifted at one end, yields to the pressure, and from the half begins to bend as it is lifted, and as the lifted end is raised, the bend approaches nearer to the further extremity. On the lifting power becoming relaxed, the stone reverts to its former level.—*Calcutta Paper.*

TABLE OF ARCHITECTS.

Sir—There was more than one reason wherefore I did not give authorities for the names introduced in the Table of Architects. In the first place, I did not imagine any thing of the kind would be looked for, it not being usual to accompany Chronological Tables with similar references; in the next, an additional column would have been required for the purpose; and for reason the third, I was of opinion that to do so, would be considered coxcombical ostentation and fussy parade. I should have had to make out a catalogue of journals and books in nearly half-a-dozen different languages, Italian, Spanish, French, German, and Russian:—and to what purpose would it have been to have referred your readers to the Khudozhestzennya Gazeta for an account of Voronikhin, and of Thomond,—to the Entziktopetitzeskii Leksikon for a notice of Bazhenov, and so on? If your correspondent is desirous of meeting with a memoir of Don Ventura Rodriguez he will find one in Jovellanos' Works, but then unless he happen to possess the latter, where is he to meet with them?—certainly not in the British Museum. Of most of the other Spanish architects inserted in the Table, notices will be found in Llaguno and Cean-Bermudez, and Ponz. Relative to Quarenghi, some information may be found, prefixed to his Fabbriche e Disegni. Of Cagnola various notices have appeared in the Biblioteca and other Italian Journals, and there is also a memoir of him in Förster's Bauzeitung; while his countryman and contemporary Zanoja has obtained mention in an English work entitled "Notes Abroad," and a portrait of him may be found prefixed to the "Raccolta di Poesie Satiriche del Lecolo XVIII," which contains three of his *Sermoni.* As regards German architects, biographical or necrological notices of many of them will be found in Nicolai, Seidel, Nagler, the different Kunstblatts and other periodicals; but it is impossible here to specify the numerous authorities individually. A biography of Hirt, has been recently published in Germany; and there is a little meagre one of Weinbrenner by Aloys Schreiber, with a portrait that makes him look like a butcher. Count Raczynski's "Art Moderne," supplies us with some personal information relative to Klenze, Gärtner, and a few other architects, including Ohlmüller, whose name will be found in the table, and who has obtained a little biographical niche in the Penny Cyclopædia.—Apropos to Klenze, if the portrait given by Raczynski be a faithful one, his countenance bears a very strong resemblance to Nelson.—Having got upon the subject of likeness and portraits, I may be allowed to remark that that of Il Cavalier Quarenghi, prefixed to his above-mentioned collection of Designs, has a look of most imperturbable stupidity:—let us hope that the artist to whom he sate betrayed instead of pourtraying his physiognomy.—One omission in the Table lies heavy upon conscience, to wit, that of the name of Francis Johnston, of Dublin, architect of the Post Office, Richmond Penitentiary, St. George's Church, and other buildings in that capital, one of which is that for the Royal Hibernian Academy, which he erected in 1824 at his own private expense, and bestowed on the members;—an act of public spirit in a private individual which would here have been trumpetted in every newspaper through the country, as one of unparalleled munificence. I almost deserve to be horsewhipped for having forgotten such a man; and the more so because I have a fine portrait of him after a painting by T. C. Thompson, R.H.A., remarkable for the vigorous intellectual expression of the countenance and the animation of the eyes; on which account it forms a striking contrast to the dull fat-headed-looking phizes of Weinbrenner and Quarenghi. Just at this moment, unfortunately, I cannot refer to the Annual Register, where I could obtain the precise time of Johnston's death.

There certainly is room for doing much in the department of architectural biography both English and Foreign, for the period comprised in the Table. The greater part of the lives would be entirely new in our language. But then *cui bono?*—would more than half-a-dozen persons among the public, and about as many among the profession, care for such a work? It would be ruinous to a publisher unless he were to undertake it out of sheer public spirit, making sacrifice of the entire cost: and therefore if anything of the kind were ever to be attempted, it should be by such a body as the Institute.

W. H. L.

P.S. With regard to the names of Craig, Pilkington, Byfield, &c., whom another correspondent has pointed out as having been omitted in the Table, it is sufficient excuse to say that I have never met with them anywhere, therefore they can hardly be of any note, certainly not of any historical importance. A line must be drawn somewhere, otherwise, if all the illustrious obscure are to be included, any table or list of names would be amplified to the extent of a Court Guide, and would become quite the reverse of a synopsis for reference. Methinks, too, the party who has called attention to the above-given names, might, at the same time, have stated what are their claims to distinction.

WHITE'S PATENT BRICK AND TILE MACHINE.

Specification of the Patent granted to James White, Lambeth, in the County of Surrey, Engineer, for certain Improvements in Machinery, for moulding Clay to the form of Bricks and Tiles, and for mixing, compressing, and moulding other substances.

The first part of the invention relates to a mode of forcing clay through moulding orifices by the pressure of inclined surfaces. Secondly, to the application of hydrostatic lubrication to facilitate the movement of the clay during the process of compressing and moulding it. Thirdly, to a mode of mixing, compressing and moulding peat; and fourthly, to a mode of compressing and expelling the water from peat-moss, by the superincumbent weight of the atmosphere.

Fig. 1 is a plan of a machine constructed according to my invention for moulding clay to the form of bricks and tiles with a portion of it removed, and Fig. 2 is an elevation of the machine with several parts of it in section, for the purpose of showing the internal construction more clearly. Fig. 3 is an end view of the cutting apparatus which divides the moulded clay into the length required, removed from its place, which is in front of the machine. There are two, one on each side, as represented by the plan, fig. 1.

In preparing the clay for moulding, when necessary to crush it, I prefer to do so between rollers grooved and ribbed. The ribs of the one working into the grooves of the other, which will break up the clay more effectually than by crushing it between two rollers, having plain cylindrical surfaces.

When the clay has been prepared for moulding, it is conveyed into the machine by the aperture *a*, fig. 2, on an endless band or by a shovel, or the aperture may be lower down opposite the screw *b*, on the hollow lubricating shaft *c*, and the clay impelled into it direct by the force of the crushing rollers; in this case the screw may be placed in a horizontal position, and the aperture *a* be above it. The power which gives motion to the machine is applied to the vertical shaft *d*, and by means of the pinion *e* working into the wheel *f*, the screw and shaft *c* are put in motion. This shaft is supported and retained by one bearing at top, and the screw *b* is turned and fitted to the cylinder in which it revolves at bottom. There is a stuffing box *g* fitted to the top of the lubricating shaft *c*, which receives the end of the pipe *h* that supplies the chamber in the shaft with water. When the machine is used for making bricks and tiles a brass plate *i* is screwed on the lower end of the shaft *c*, and prevents the water which it contains escaping in that direction; but when it is used for making circular tubes, the plate is removed, and a plug *j* inserted, which forms the inside diameter of the tube as shown in fig. 4, and the water is then permitted to percolate that way. The clay is lubricated from the spiral plane of the screw *b*, by having a radiating channel from the chamber in the shaft *c*, into which very small holes are drilled, for the water to escape by. There are also lubricating joints, or channels, in the flanges at the top and bottom of the cylinder in which the screw *b* revolve, marked *k k*, in the different figures, and similar joints or channels are formed round the orifices or moulding openings, from whence the clay exudes from the machine by the propelling power of the screw; and I would state that these lubricating joints or channels, may be differently constructed without departing from my invention, so long as the application of hydrostatic pressure in supplying a fluid to them is retained.

Fig. 2, *l* is a section of a vessel containing water from which several pipes with brass cocks on them convey water to the lubricating joints in the top and bottom of the cylinder, in which the screw revolves, and also to the shaft *c*, and the lubricating orifice, in the chamber *m* from whence the clay exudes. The clay with which the machine is charged by the aperture *a*, fig. 2, is drawn into the spiral plane of the screw *b* as it revolves, and impelled into the bottom chamber *m*, from whence it escapes in two streams in opposite directions as shown in fig. 1, by *n n*. When different figures are required to be moulded, it is only necessary to change the chamber *m*, and apply one having an orifice of the form wanted. Fig. 5, is face view of a lubricating orifice for forming bricks, and fig. 6 a similar view of one for making common draining tiles. In both these figures the lubricating channels round the orifices from which the clay exudes, are represented by strong dark lines.

In dividing the moulded clay into the lengths required, the screw *b* makes a brief stop at that moment, and consequently the clay to be cut. The pinion *e* is loose on its shaft, and resting on a collar as shown in fig. 7, which is a section of the pinion and toothed clutch-box *o o*, which turns it. When the toothed clutch-box is withdrawn from the pinion, as will be presently described, the shaft *d* may turn, and the pinion *e* with the apendage it drives remain stationary, until the clutch-box is forced up again to its present position by the spring *p*. It is withdrawn twice every revolution of the shaft *d*, by two inclined planes *q q*, depressing the roller *r*, as they alternately pass over it, as may readily be understood by reference to the drawing. These planes *q q*, can be regulated to cut the moulded clay to any length produced from one revolution of the shaft *d*, simply by increasing their number or adding to the length of their planes. In addition to this mode of cutting various lengths by my machine, the horizontal shaft *s s*, of the cutting apparatus shown in fig. 1, can be extended and several cutting instruments *t t*, fixed at given distances from each other, and all of them made to operate at the same instant. The levers *u u*, give motion to the slide *v* which carries the cutting instruments *t*, as shown in fig. 3, at the time the clutch-box *o o* is withdrawn from the pinion *e*, by two quadrants or inclined planes *x x*, fixed on two circular plates shown on the shaft *d*. The dotted lines represent the vibration of the levers, and it will be seen that the clay is cut, and recut by their motion. Fig. 8 is a plan of the slide which is used for cutting circular tubes, it is moved by the horizontal shaft *s s*, vibrating two levers through openings in the top plate of the machine shown in fig. 1. In forming principal drains with these tubes, I recommend short circular soles to support them at the joints, the soles may be moulded after the manner described for making common draining tiles, and cut into short lengths by a circular saw after the clay is sufficiently dry for burning. The advantage of forming principal drains with circular tubes is very obvious. They are stronger with less material than any other figure having the same internal capacity, and they also offer to the water greater facility to escape, than would be the case if it were running over flat surfaces, in addition to which, the expense of procuring them is greatly diminished by my invention.

In the event of the machine fig. 1 and fig. 2 being employed for mixing, compressing and moulding peat, I apply knives on the screw shaft, and also round the circumference of the cylinder in which it revolves, making in fact an ordinary pug mill by which the materials will be mixed and blended together before they arrive at the screw, where such materials will be pressed and moulded into rectangular bricks, and may be cut by the apparatus described.

Another part of my improvements relates to the compressing of peat by the superincumbent weight of the atmosphere. To effect which I form a large vessel of any known material that will keep it sufficiently air tight, such as iron, slate, or stone, a few inches from the permanent bottom of this vessel, I place another full of small holes and support it on the former, above the one full of holes a layer of coarse cloth is spread, upon which the peat to be compressed is laid to about 12 inches deep. The length of the vessel is immaterial, provided it being sufficiently air tight. One, however, 200 feet long by 6 feet wide, would be a proper size for compressing about 40 tons of peat at one time. When the vessel has been charged, the peat is to be well blended together, which may be done after the manner clay is made to combine in forming the bottom of a canal when making it water tight, and it is also to be well pressed to the edges of the vessel, to prevent as much as possible the air descending by it, or through it, in a downward direction. When the top surface of the peat has been well secured against the admission of air, a communication is to be opened with an air pump, and the air exhausted from the space between the two bottoms which will cause a partial vacuum below the peat, and thereby offer to the water which it contains great facility to escape. At the same time the pressure of the atmosphere on the top surface of the peat will be in proportion to the exhausted state of the air below, and the whole mass will be compressed, and the water which it contains will be carried away by the air pump, after the manner the air pump of a condensing steam engine performs its office.

When the peat has remained in the vessel or pit sufficiently long to be reduced to about one-third of its original depth, it is to be removed and properly dried by any of the modes in use. In removing it, it may be readily cut into regular sizes by having a carriage to pass over it with knives projecting downwards, and so placed as to divide it into a number of slips about 4 inches wide, and these may be cross-cut into lengths of 8 inches, which is found to be a good size for drying.

Having described my improvements for moulding clay to the above mentioned purposes, and also for compressing peat, I wish it to be understood that I do not claim any of the parts, which are well known and in use for moulding clay and compressing peat; but what I do claim as the first part of my invention, is the application of the inclined surfaces of a screw to press clay through moulding orifices as above described. Secondly, I claim the mode of stopping the moulded clay while it is being cut as above described. Thirdly, I claim the mode of lubricating the clay with water when being moulded by pressure through moulding orifices as above described. Fourthly, I claim the mode of mixing, compressing and moulding peat by means of a pug mill when combined with a screw to compress and mould the peat through moulding orifices as above explained; and lastly, I claim the mode of compressing peat by the pressure of the atmosphere, and separating the water from it by a pump as above described.

ON THE HORIZONTAL AND PERPENDICULAR LINE IN ARCHITECTURE.

By Frederick East, M.A.

I was at the Institute the same evening that Sir Gardnor Wilkinson, a gentleman of great acuteness, tendered to its members certain impressions produced upon his mind by the prevalence of the horizontal or perpendicular line in architecture. Sir Gardnor, however, from a certain politeness of feeling, did not extend his observations to any length. He conveyed them rather in the shape of suggestions, with a view to elicit from the profession more enlarged views upon the subject. Probably in harmony with that wish it was that Mr. Godwin entered the field, and favoured us at the last meeting with a passing and pertinent criticism upon the perpendicular line. But the bearing of his criticism affected the frequent use of a column breaking from the main entablature and exhausting itself in a figure. He considered it as a mere excrescence, giving perhaps too much importance to sculpture, which I conceive most will admit as only accessory and secondary to the design. Hence it was employed without judgment or feeling when evidently a mere prop or support for the statue. His observations seemed, however, limited to this; they appeared to penetrate no farther than to show this fallacy in taste. I can only regret from the clearness and conciseness of those remarks that he did not anticipate my own, and that the subject was not more indulgently treated by one so much more competent to give them.

Feeling, however, that it is expedient to detect the true spirit of a composition, and of the minutiæ which compose it, in order to guide our own taste; and that no satisfaction can result from the mere knowledge of the existence of this or that style without we can apply it to our own erections, if harmonious, or shun it, if discordant: I humbly introduce my own impressions on the subject, which I offer, however, with submission to the profession, as before men, some of whom are no doubt perhaps more fitted to impart information, than to receive the s ightest observation, or the smallest wrinkle from me.

By a consideration of the prevalence of these lines, so marked, and prominent in the palaces and churches of Italy, in the middle ages, we naturally trace out the real secrets of beauty in foreign creations, and are enabled to judge whether they accorded with the spirit of the times, and consequently with the beauties of real expression, as it was then influenced. By this means we may avoid passing a hasty censure upon that which to an edifice in this country would be certainly destructive to true taste, and which we could never imitate but under similar circumstances.

Notwithstanding the correctness of Mr. Godwin's remarks, I conceive a more powerful motive, than to give effect to sculpture, influenced the adoption of the per,endicular line, in the purer days of art. And that however a series of columns might have been afterwards sacrificed to the beauties of a figure or the ornaments of sculpture, their use sprang originally from the poetry of nature and the resources of Italian fancy.

I conceive that great poetry and pathos—pleasing emotions, or gloomy ideas are consequent upon a skilful appropriation of the perpendicular or horizontal lines. A partiality for the former when decked with the garlands of nature, enlivening us with gaity and mirth, and exhibiting in its tapering lightness, all that seduces and captivates; whilst great indulgence in the latter instils awe and inspires some idea of the terrible and sublime.

To illustrate my meaning more clearly, I would make solid simplicity, weight, dignity, &c. to repose upon the horizontal, whilst elegance and grace should seek their beauty from the perpendicular. Because there seems to me something of phisiognomy in architecture,—a character about it—so that we are either amazed, awed, softened, or delighted, by its mien and general bearing.

When therefore we search after grace, nature reveals it, sporting and skipping in lightness and elegance, never so beautiful as when in action and erect, seldom shortened into repose. Hence the taperings of the Gothic, and the careless lightness of the Corinthian. Hence also the prevalence of the perpendicular, which might tend to insignificance in a building, but for a certain symmetry of parts, easily detected in works of acknowledged merit. But to fashion the grand, the solemn, the imposing edifice, we instinctively turn from any thing feminine or slight. Like laughter and mirth they become noxious to our sterner moods, and nothing satisfies but a certain breadth of parts, a rigidity of aspect, a dignified reserve as we search for the sublime. Nor does any loftiness of character, nor height of form display itself, but what seems natural upon the breadth, merely in fact, a necessary proportion, to avoid contempt and ridicule. Thus perhaps it was that horizontal lines were sometimes preferred for the Italian palace; though oftener defeated in effect, by the lurking fondness which Italian artists had, for fanciful embellishment, giving occasionally an eccentric and inappropriate feature to an otherwise imposing front.

The adoption of the one style or the other results, I conceive from the spirit of the times. The artist wished to change the dull monotony of a mass, to give life and sprightly features to the building. To deck the edifice in all the fashions of elegance, sought and employed qualities in form and exterior conducive to this idea.

He knew that effective grace must depend upon the happiness of contrast, and selected the perpendicular line as the best index to variety in a front of breadth and lateral bulk. In after times the church—the Roman church was to betray the resources of its wealth;—the people were to conceive a proper notion of its splendour—the terrible and sublime were to be lost, or rather to be subdued for a little, amidst images of attraction and wonder. Hence the artist digressed, and violated symmetry, to court the spirit of the times.

Or the Ducal palace was to awe the passer by, the vassal was to shrink when near the presence of the great. Hence the judgment of the artist fed the noble's pride, by investing the edifice with all that indicated the sullenness of grandeur. The horizontal line traced itself all through the edifice, or was broken by a wing or a centre of richness and tapering forms, as if to intermix with so much oppressive dignity some picture of splendour and elegance too.

There seems no exact standard to test the merits of either grandeur or grace, yet to, a mind susceptible to and attracted by natural elegance or the pure distinctions of art, first impressions are generally most correct. Without entering however into examples which are unnecessary, if the moral of the sentiment be imbibed, and we can only trace the principle affecting the application of either to its true source, so as to assist our own ideas of correct taste and of purity in design. I shall in conclusion merely test these opposites in art, by a comparison with two opposites in nature—and would remark that as we love in woman with her laughing eye and elegance of motion, that aërial lightness, that sylphlike form, which facinates and enchants; so we expect that compactness, that breadth,—that stern solidity of air in the more dignified lord of earth. And that whereas we cede to woman with her loveliness of grace, gaiety of attire, and profusion of ornament as an increase to her charms, so we expect not to find the majesty of man masked by a whimsical dress, or cloaked by a frivolous garb. Presuming at the same time that the coldness of our fancy may lessen the contrast, and account for our giving the swellings and undulations of grace less prominence than accorded with the fire,—the energy of the ardent Italian.

Whether we transport ourselves to Vicenza and see the edifices built or restored by Palladio, or follow our own great genius of the same school Inigo Jones, into the harmonious distributions of the flat and void of the sombre and light—we see a felicity in outline, a play in effect, in which ancient beauty is reproduced and revived in combinations unknown to antiquity. This beautiful harmony seems to me the effect of lines. In the great front of the design for the Whitehall Palace, where the façade is long, we see with what consummate skill in the combination of lines, Inigo Jones pleases the eye, to a length of 1151 feet. How in the centre, column rears itself above column. How the whole centre itself is elevated—what a noble attitude it has! how rich and yet how symmetrical! Contrasted against this front of elegance comes a void where naked simplicity reigns—where little or no ornament appears—where little of what is tapering is seen—and the eye which seemed to soar up the rich and elegant columns of the centre, now wanders along the broad g oomy silent mass which intervenes.

This you see is depressed—is lower than the centre—the idea of breadth is at once visible, and the contrast with the lofty centre is apparent—and thus the effect is virtually speaking one of lines. This idea of harmonious distribution is visible in the centre itself. There to give importance to that part in so long a façade, the length of it must necessarily be great, and to remedy this Inigo Jones introduces two towers, the relief of which and their tapering appearance is very striking and effective.

As you progress along the front you catch once more the lofty wing, the columns, their statues, and the frequency of lofty lines is again seen, and your eye wanders as it were between dullness and life. This peculiarity—this attention to the varied employment of lines is peculiar to others as also to Palladio, and to be seen in his Palazzo del Capitanio and other buildings at Vicenza.

The introduction of columns in a long continuous edifice seemed not only to give the idea of support but to create variety.

Assuming this, it is somewhat singular to compare any Grecian temple with any mansion erected by Inigo Jones—or any palace erected by Palladio. We see at once by what a different method the Grecian artist produced variety in his edifice. The Greek was all simplicity—his outline was distinct, symmetrical, unconfused, and shadowless, except the portico. And variety instead of being beheld in the body and bulk of the temple, is seen rather rambling in the cornice, whilst reliefs are visible in the mouldings of the architrave, and the figures of the frieze.

To analyze this subject more closely, however, it becomes necessary to class the peculiarities of the perpendicular and horizontal lines according to time, and as seen in the various countries of architectural renown.

The descent from the classical originals in art was by a comparison with Grecian art, where symmetry ruled design to introduce extremes. And though we see effective compositions in Italy and elsewhere, we perceive that the bent of innovation was to introduce the perpendicular—only slightly seen at first—with the tendency to give altitude, appearing but faintly, gradually, and then only in a part of the edifice, undiffused.

The tower or some part en masse reared itself square, and without pilasters or columns at first even solid itself in plan, but this very contrast to the other part showed the perpendicular in its infancy. Until as the debased Roman architecture of the lower empire which forms the foundation of the Saxon, Norman, and Lombard school became successively improved in England and the north of Europe, the perpendicular found its way into those beautiful modifications, termed Gothic—and finally in the religious edifice became invested with a charm to an Englishman's fancy. For up these columns in the cathedral the eye wanders for repose, but finds itself lost in the intricate beauties of the roof, and rambling amidst the strange and the wonderful, as amidst types of the vast and incomprehensible creator.

To trace the first change from the severe to the elegant, from the breadth of dignity to the delicacy of after times. We find before the invasion of Greece by Xerxes, the Doric was the only order known. Pericles and Cimon, however, on the rebuilding of Athens, by the introduction of the Ionic order from Asia into Attica, invested the ancient massive simplicity with something of the lightness and elegance of grace. The Corinthian soon after invented, introduced more softened beauty into the taperings of elegance. The edifice before this indebted to Doric proportions for its effect, becomes now more lofty and chastely beautiful without violation to the simplicity of the whole. And this change is of great importance, when we consider in a Grecian temple that the circular of the column is in itself a relief, that the peculiarity in change is that although the result is elegance itself, as a whole the principles of the change are very slight.

Turning from Greece to other states of importance, who for convenience snatch their ideas from the polished and the civilized. The Roman appears crude at first in his attempts, alive to the beauty of Grecian proportion, but fashioning a style therefrom peculiarly his own. Unpossessed of the coolness of the Grecian, we see his ideas extending, the principles of his composition different. Unsatisfied with the novelties of ornament and recesses, he must pierce the sky—and we find the Pantheon in its dome, the bursting as it were of variety, as a grand feature (and this the result of altitude) from the cradle of ideal taste. We see here the great father of lofty turrets, tapering domes, campaniles and minarets, which with the declining power and fading grandeur of Rome became so welcome to the Italian artist.

The removal of the seat of empire to Constantinople accelerated the change—St. Sophia and its minarets betray it—and at length variety became too important. That which appears a foil to the Grecian edifice appears no longer such in the Italian. The old relics of grandeur were neglected—Venice and Pisa new-born and wealthy sought their artists from Constantinople, and the old standard of Roman excellence and pure dignity became less and less visible in the Lombard barbarians. The Saracen, the Moor, the Lombard and Italian, evince so many poor attempts to turn classic symmetry into their own love of tapering forms and fanciful outline. The Ducal palace at Venice has the very corners cut away to admit a thin column—lightness is seen here where strength should appear—a fret work of shafts is the support of an impending weight, and the whole is distortion.

Palladio however seems distinct from these errors. In the Redentore church, Venice, Palladio gives a lofty elevation—the dome diminishing in contour terminates in a figure. The dome itself is winged by turrets pierced above and capped by a cone. The whole is lofty and imposing, because pettiness in ornament is unseen; and the statues are judiciously placed uncrowded, and themselves important features, but the whole is but the grandeur of the perpendicular. In the San Petronio di Bologna a change appears, with the same love of tapering forms, the same hankering after the perpendicular we lose the grandeur of parts in the horizontal breadth, the intersections of the cornices, the play of breadths, the friezes are scarcely relieved by the height of the centre, by its diminution, by its statues, or balanced by the pyramidal terminations of the wings.

The descent from the purity of Palladio was evinced by a frequency of columns, but then again to have these, induced another fashion of variety. To relieve the multiplicity of columns from offence, horizontal lines were introduced; cornices traced themselves throughout and extended their fatherly protection to a host of trifling perpendiculars. In the Baptistery at Pisa we see this, and most of those cities not removed from the pale of the remains of Roman taste, displayed this confusion of lines. Proceeding in the direction of Milan, we find Lombard Gothic and orders all united. And the miscellany, as in Milan cathedral, seems to reminds us of the full grown dignity sometimes seen in a dwarf, mixed up with his littleness of parts. Removed from the relics of classic influence we find the perpendicular gaining ground, we see the edifices of northern Europe, of Normandy, &c. beautiful and their own—elegant though profuse—lovely though intricate. Turning to Sicily we find the Normans introducing a mixture of their own with the Saracenic; and the cloisters of Monreal, the Alhambra of that country, abounding in columns twisted, spiral, light, and yet singular, a mixture of perpendicular and arch—full of wild and fanciful conceptions. In Florence we find the great exactness in the horizontal. The palaces there are so many feudal residences—edifices nearly 300 feet in length, in which the stylobate runs along the whole façade where the windows are widely apart, and the very roof frowns upon you.—The subject is a curious one, it opens a wide field of information to the antiquary and artist—but to unite these two lines is the secret of expressing charms, and we love the harmonious union as we love in the broad landscape, the lofty tree, the distant mountain, or a church tower, and thus by grasping the great principle of effect in nature, we possess the most mighty wand in creating and displaying the perfections of the beau ideal.

FREDERICK EAST, M.A.,

Leigh House, Tooting, Surrey.

EXHIBITION, ROYAL ACADEMY.

ARCHITECTURE.

It is with regret we feel ourselves compelled to commence our report by stating the present exhibition to be the least interesting one for many years past; not because it contains a greater number of inferior designs, but because there are much fewer of an attractive kind than usual. Always has there been a great deal of trash, but there have generally been many designs forming redeeming points—cheering *oases* amidst the surrounding desert; whereas, this year, the latter are both more rare and less brilliant. A desert, however, will not be thought the most appropriate simile, the walls being, on this as on every other occasion, crowded and crammed from the floor to the very top of the room. Whether this system has any influence at all upon the quality of the drawings admitted—whether some are not admitted merely because they happen to fit *nicely* into vacant places, while others are turned out because they cannot be hung up without disarranging something else, or perhaps causing a few square inches of wall to be left bare, we know not; which being the case, we are bound to presume that merit obtains preference with the Academy; yet if so, what opinion are we to form of the designs which are turned out? At all events, the Academy seems to act very naturally, because, like Nature herself, it evidently abhors a vacuum—upon its walls—no matter what is hung up in order to avoid that evil.

To be more serious—we have little doubt, for our own part, that the public are deprived of seeing much that would be creditable to the profession, solely because architects are deterred from sending drawings to the Academy, being aware that the space allotted to such subjects is so utterly inadequate, that it becomes a mere chance whether they can be received, or if they are, whether they will not be put completely out of sight, as is invariably the case with a considerable proportion of those which are received. In fact, there ought not to be more than two ranges of frames hung upon each wall, on what is technically termed the line, which space, being now generally occupied by the larger and more prominent drawings, the lesser ones, which—supposing they are worth looking at at all,—ought to be hung as near the eye as possible, are placed either so much above or below it, that it is frequently barely possible to make out their subjects. Thus the catalogue may be said to be in a great measure quite delusive, promising us what appear to be interesting subjects, and when we enter the room to look for them, we find that several are scarcely to be found out, and when discovered, all that we can discern of them is, that there is something behind a glass within a frame. In many instances, perhaps, we may lose nothing by not being able to obtain a more satisfactory inspection, but there are also others in which the being prevented from doing so is highly annoying and tantalizing. An instance occurs in the present exhibition, with regard to No. 959, "View in St. Peter's at Rome, displaying the general decorative character of the interior," by J. H. Steinmetz, which appears to be one of the most tasteful and interesting drawings in the room, beautifully coloured, and treated with the feeling both of a painter and an architect. We say "appears," because it is placed so high that it is impossible to judge fairly what it is. It may, perhaps, in consequence, look to be more elaborately finished than it really is: but then it is just as likely that we now only discern the general effect, and that the beauties of detail and execution are lost: at all events, it is provoking to meet with something seemingly so very good, so disadvantageously situated, while many things, scarcely worth notice, are thrust full in view. We should say that, considering the great size of the drawing, and the familiarity of the subject, Mr. Hardwick's View of the Railway Terminus in Euston Square, might very properly have been mounted a stage higher, more particularly as another drawing of the same building was exhibited by him on a former occasion. Inordinate space, too, is occupied by No. 914, "Remains of the portico of the Lesser Temple at Baalbec," which has hardly any right to appear in the Architectural Room at all, unless it had been elevated among the oil pictures which serve as filling up stuff to hide the upper part of the walls. It is true both Hardwick and Roberts are associates, and may, so far, have the privilege of getting better places than their neighbours: yet that is but sorry satisfaction to us who go to look at the designs the catalogue promises us. No. 912 is a drawing that ought to have been hung level with the eye, whereas, for the very reason that it is small, it is actually *floored;* so that it is impossible to examine it without stooping in a most painful attitude, there being not a single chair in this room on which a person may sit down to look at any thing so placed; which, by the bye, seems to be pretty much of a piece with the other *judicious* regulations. However, any kind of accommodation, we presume, is considered good enough, both for those who send and those who go to look at architectural drawings. Surely there must be some other room or rooms on the ground floor of the building, capable of being made use of during the exhibition for works of this class; while their being thereby kept quite apart from the pictures and other drawings would, in fact, be a decided advantage in itself. If nothing better can be done, we see no reason wherefore a line of architectural drawings should not be hung up in the hall, on a screen about five feet high, before the pedestals of the statues facing the stairs. To be sure, only a very small number could be so disposed; yet even were no more than a dozen meritorious subjects so placed, where they could be distinctly examined, it would be a great improvement, and we should feel grateful for it. We made remarks to the above effect in our very first volume, and ought, therefore, perhaps, both for that reason and because we are now convinced how utterly unavailing they have been, to desist from all comments of the kind. Yet the evil itself is so scandalous, so contrary to common sense, that we must lift up our voice against it from time to time, in the hope of thereby inciting others, and the profession generally, to take some steps towards bringing about a reform, which we can only recommend. What, we ask, is the Professor of Architecture and the Architect-academicians about, that they look upon such absurd doings without interference? Do they ever look into the Architectural Room at all? Whether they do or do not, they have equally much to answer for.

Again, we ask, what is the Professor of Architecture about? for we do not see a single drawing by him. Is his office become altogether a sinecure?—he gives no lectures, he exhibits no designs; therefore let his qualifications for office be as great as they may, they are at present quite nugatory and valueless. Most assuredly he does not follow in the footsteps of Soane, who whatever his other failings might be, was certainly diligent and zealous in the discharge of his academical duties. It is no excuse at all for him to say that Mr. Cockerell has probably been prevented by his private engagements from devoting any time to Exhibition-drawings, because, as is well known, the latter are as frequently as not made by artists employed by the actual authors of architectural designs; and we have heard that Mr. C.'s own "Tribute to the Memory of Sir C. Wren" (see our first vol. p. 251), so much admired for its pictorial effect, was the work of another hand, so that his share in the drawing amounted to no more than the idea of bringing together Wren's principal buildings into a single picture. Surely the present Professor might have allowed us to see some drawings of the Libraries he is now erecting at Cambridge, and also the design which has proved the successful one in the competition for the Randolph and Taylo Institute at Oxford; some of the rivals of which are here to be found—in the catalogue at least, if they are not all to be seen where they have been stuck upon the walls.

We do not, however, find among them any drawings of the design sent in for that building by Mr. Hallman, (author of the essay on Graeco-Russian architecture, which will be found at page 93 of our present volume,) although it has been described to us, by one who has seen it, as being one of very great merit and beauty, which, to say the truth, is more than we dare affirm of any of those we here notice, for they strike us as being of a very so-soish character. Whether Mr. Cockerell's will, as it certainly ought to do, hereafter satisfy us that it was deservedly preferred to Mr. Hallman's supposing the last to possess the taste and originality ascribed to it by our informant—remains to be seen; though we strongly suspect that originality and taste are almost the very last points taken into consideration upon such occasions.

Among competition drawings are one or two for the Royal Exchange, also for St. George's Hall, at Liverpool, and we should probably have beheld some of those for the Assize Courts also, at the latter place, had they been returned in time for sending them to the Academy. Next year, however, we shall doubtless meet with some of them, but whether with that which has obtained the first premium is questionable, because Mr. Elmes has not thought proper to exhibit his design for the St. George's Hall, though it must be poor indeed if it shrinks from a comparison with Mr. O. Jones's or Mr. Alexander's. We do not like Mr. Jones' (Nos. 97 and 1046) at all: it is in a sort of Alhambra-fashion, but after such fashion as to give us what is offensive in it, without what renders it charming. Of Mr. Alexander's we can judge only of the interior of the Hall (No. 917), but if its chief merit lay here, and it was on this account that the second premium was awarded to it, we must confess, we look with trembling towards the design which bore off the first prize. We have heard that Mr. A. himself was somewhat astonished at his success, and so too are we when we look upon this specimen of his architectural invention and taste: for it is a sort of Meeting-house affair with a few showy columns forming a gallery around the upper part like those in our modern churches, and is about as original and as classical. The gaps between the columns have certainly one advantage, which is that there would be very few of those inconvenient pillars to intercept the prospect of what the newspapers style "the galaxy of matchless beauty and loveliness" that invariably graces all festive meetings where ladies are admitted to be spectators. Accordingly we have here a display of lovely bonnets and dresses perched up in the galleries, and if such display can excuse the poverty of the architectural one, gallantry we suppose ought to get the better of grumbling. No. 977, another design for the same building by Mr. Bardwell, being a perspective view of the exterior, appears to possess a good deal of merit and some originality of character; but we are compelled to speak thus dubiously as its situation prevents its being examined, at any rate without getting a cramp in the neck.

We meet with other competition productions in Nos. 1046 and 1001, both for the Nelson Monument, viz., the latter a model of Granville's design for a cast iron column, the other Mr. Goldicutt's colossal globe—we have heard it called "Goldy's Pill"—for the centre of Trafalgar-square—and which is mystically designated in the catalogue "A Vision of the nineteenth century"—a very taking title, no doubt.

Neither of Mr. Barry's subjects (Nos. 923 and 839) have quite satisfied, or rather both have disappointed us. The front of the Unitarian Chapel lately erected at Manchester, is undoubtedly very far above the average, and is judiciously treated inasmuch as it is not made to look like a model for a large building executed upon a small scale. Yet while there is nothing to censure, neither is there any thing particularly to admire. The other design "for the additions and alterations at Highclere, the seat of the Earl of Carnarvon," shows the proposed conversion of a plain modern house into a mansion in the Elizabethan style, by the addition of turrets at the angles, and the refacing and decoration of the other parts. The circumstance of the architect's being fettered by the necessity of adhering to what is already erected, as regards the general form and the position of the windows, prevents us from considering this a specimen of what he would do if left entirely to his own ideas for such a subject: still we should have expected from him greater freedom and taste in the application of that style and its details, which he seems here to have merely copied, without attempting to infuse into them any originality, or in any degree, refine them. It is by far too strictly faithful to that style to be much to our taste; nor can we conceive what there is in the latter to recommend it to the favour it has of late obtained; for at any rate it is neither economy nor elegance: more likely is it to be the disgust of the soi-disant Grecian insipidities—bald and staring sash-windows with a few columns stuck upon before them, by way o portico, that has occasioned a relapse into the stiff, formal, and fantastical quaintness, and little frigid conceits of this semibarbarous manner, which, as it has always appeared to us, originated only in a blundering, awkward imitation of the Renaissance style on the continent. Undoubtedly there is frequently, in spite of all this, a good deal of piquant and picturesque in our examples of this class. The proper course, therefore, would be to study and select those qualities, carefully eschewing at the same time, all the coarse dross and rubbish, and the gingerbread puerilities among which they are found, but which certainly do not tend to give them any additional charm.

(To be continued.)

STONE FOR THE NEW HOUSES OF PARLIAMENT.

Sir—Several paragraphs on the subject of the stone to be used in the erection of the new Houses of Parliament having appeared in many of the London and provincial newspapers, which contain some inaccuracies and mis-statements, it may not be amiss to set the public right in a matter which, though not of great importance, has yet some national interest.

It is, of course, well known that the Commissioners appointed to visit the quarries, and to inquire into the qualities of the stone to be used in building the new Houses of Parliament, in their report addressed to the Commissioners of Her Majesty's Woods and Forests, after giving a variety of details respecting the numerous quarries they had visited, the buildings they had inspected, and the experiments which had been made to determine the physical and chemical properties of many kinds of stone, specimens of which had been obtained, conclude their report by stating that having weighed, to the best of their judgment, the evidence in favour of the various building stones which had been brought under their consideration, they felt bound to state that for durability, as instanced in Southwell Church, &c., and the results of experiments, for crystalline character, combined with a close approach to the equivalent proportions of carbonate of lime and carbonate of magnesia, for uniformity in structure, facility and economy in conversion, and for advantage of colour, the magnesian limestone or dolomite of Bolsover Moor and its neighbourhood, was, in their opinion, the most fit and proper material to be employed in the proposed new Houses of Parliament.

Bolsover Moor is an uncultivated and rocky waste in the parish of Bolsover, in Derbyshire, a short distance north of Mansfield, and is the property of Earl Bathurst; its locality, immediately on the publication of the Commissioner's report, became, of course, an object of great interest, both to the noble proprietor and to the various parties interested in procuring stone for the great national erection; but on a more extensive and particular inspection of the beds on the Moor, than the Commissioners had been able to make of them, they were found to be deficient in their capacity of furnishing blocks of a size and form, sufficient and proper for the purposes required in the proposed erections. New speculations, therefore, arose, and fresh hopes were excited amongst the many candidates for the honour of supplying the material for the buildings: it, however, was the fortune of Mr. Charles Lindley, of Mansfield, an extensive builder and quarry owner, to discover at Mansfield Woodhouse, about a mile north of Mansfield, another bed of the Bolsover Limestone, extending over a considerable tract, of a quality and character precisely similar to that of the beds on the Moor, and which promised to furnish blocks of a size and form suitable for the purposes intended. Mr. Lindley immediately, and upon speculation, at a considerable price made a purchase of the land, which was of little worth for agricultural purposes, though occupied for them, and having submitted specimens of the stone to the proper authorities, which, being tested, were found to possess the requisite qualities, and therefore proper to be used in the erection of the new Houses of Parliament. Shafts were thereupon sunk, to ascertain what the nature and extent of the beds were that the field contained, and the result of the trials being also satisfactory, workmen were immediately employed to get stone, and numerous blocks of considerable size and excellent form were speedily obtained.

The contractors for the works, with a professor of geology, visited the quarry, and there being every appearance that the field would yield a sufficient supply of material, a contract was entered into with Mr. Lindley, and he is now actively engaged in forwarding a regular supply of stone to London.

Mr. Lindley is also the proprietor of an extensive quarry of white sandstone (magnesio-calciferous sandstone), at Mansfield, which is also highly spoken of in the Commissioners' report for its appearance and durability; this quarry will yield blocks to the size of 10 tons, and the stone will work well with the Woodhouse (Bolsover) stone, a great advantage is thereby gained, because the sandstone may be used for purposes to which the limestone may not always be suited.

On reference to Table A in the report of the Commissioners, pp. 12, 13, it will be seen that the Bolsover stone is described as magnesian limestone, that its component parts are chiefly carbonate of lime and carbonate of magnesia, semi-crystalline, its colour a light yellowish brown, and its weight, in an ordinary state, per cubic foot 151lb. 11oz. Table B states that Southwell church, Nottinghamshire, (of the 10th century) is built of the magnesian limestone of Bolsover Moor, and that it is now in *perfect* condition, the mouldings and enrichments of the doorway *appearing as perfect as if just completed*, and that the choir, which is of the 12th century, and built of a stone similar to that of Mansfield (Mr. Lindley's magnesio-calciferous sandstone), is generally in good condition.

Table C, of chemical analyses, shows that the Bolsover stone is composed of silica 3·6, carbonate of lime 51·1, carbonate of magnesia 40·2, iron alumina 1·8, water and loss 3·3. Specific gravity, dry masses 2·316, particles 2·833.

All the qualities enumerated of the Bolsover stone mentioned in the report, belong to the Bolsover stone found at Woodhouse, and, like the former, the latter is remarkable for its peculiarly beautiful crystalline structure, and is, rather than otherwise, superior in its quality and appearance.

I am, Sir, your obedient servant,
Amicus.

Mansfield,
20th May, 1840.

TEACHERS OF CIVIL ENGINEERING, &c.

Sir—In the last number of your Journal, you have inserted a letter from "one who has suffered," complaining of being the *dupe* of an advertisement in the newspapers headed "Offices for Surveying, Architecture, and Civil Engineering." Now, as I sometime ago advertized with that *heading*, and as I reckon your publication too respectable to deal in *anonymous slander*, you will oblige me by publishing the name of the complainant, so as I may learn whether the charge is applied to me, and if so, set myself right in the eyes of your readers.

I am, Sir, your's respectfully,
Edward Jones,
Author of the "Principles and Practice of Levelling."

May 11th, 1840.
21, *Charlotte Street,*
Bloomsbury.

[Mr. Jones must be aware, or ought to know, that we will not publish the names of our contributors; we consider that if there be any parties who hold out to the world that they can teach "Surveying, Architecture, and Civil Engineering," or any one branch "*in a few lessons*," they ought to be held up to the severe animadversion of the profession. This is the charge made in last month's Journal by our correspondent "one who has suffered." If Mr. Jones' advertisements do not contain such a statement, he cannot be in any way injured by the letter, but ought to be ready to support us in exposing such a practice, which exposure can only benefit, and not injure, the respectable practitioner.—Editor.]

ENCROACHMENTS OF THE SEA.

Sir—The encroachments of the sea on the coast of England having aroused public attention, a little local information may be not only interesting but useful. I have always regretted having neglected to inform you, in my former letter on this subject, that the village and church of Warden, in the Isle of Sheppy, are now covered by the sea; that since I came here in June last, a great part of Warden Point has slipped into the sea, and great part of the island, from Warden to Minster, is monthly going the same way, from underground springs and want of drainage.

In the old History of Hampshire it mentions that the people daily forded or waded across with their cattle from the Forest to "Vectis" to graze; now first rate men-of-war can sail over this place. The destruction of the western side of the island is much hastened, in consequence of the removal of stones and gravel for building and road-making.

Your obedient servant,
C. F. Parkinson, Capt. 73rd Reg.

Sheerness Garrison,
May 14, 1840.

ON REBUILDING OLD CHURCHES.

Sir—I beg to make a few remarks on the impolicy, as well as the bad taste of the Ecclesiastical Commission for Building Churches, in throwing every obstacle in the way of repairing and *restoring* old churches to their former beauty and embellishment, preferring pulling them down and building in their room, a wretched little brick building, not inaptly compared, some years since, by a celebrated demagogue and enemy to the reformed religion, to a dog-kennel tied to a sentry-box. Is it doing honour to, or paying proper respect to the cause they advocate, to consider any building, however insignificant, good enough to celebrate the worship of God in? How different the feeling in the olden time! Are we not indebted to the devotion and zeal of our forefathers for the noble architectural remains of sacred edifices, whose lofty proportions, grandeur and sublimity fill the mind with awe and solemnity?—even the Heathens honoured their Gods in stately temples. A House of Parliament, a National Gallery, a Mercantile Exchange, are justly thought worthy of a noble edifice. Is it not an insult to our God, and does it not bring religion into disrespect and disrepute, when those who ought to support, and who *themselves* live in *palaces*, consider a *hovel* good enough for their *Almighty Father*?

Scrutator.

RAILWAY COMMUNICATION BETWEEN LONDON AND DUBLIN.

The Committee appointed by the Lords of the Treasury, in pursuance of an address to the Queen from the House of Commons last sessions, "that her Majesty will be pleased to give directions that an engineer or engineers may be appointed to inquire and report upon the relative merits, and the preference which ought to be given to the respective already surveyed and projected railways following:—namely, from Holyhead, *viâ* Bangor and Chester; Portdynllaen, *viâ* Caernarvon, Bangor, and Chester; Portdynllaen, *viâ* Barmouth, Bala, and Shrewsbury; Orme's Head, *viâ* Chester:" and also, "that her Majesty will be pleased to give directions that proper persons may be appointed to inquire and report upon the best means of communication by sea between Dublin and London, as connected with the said intended railways."

The Committee have selected the line recommended by Mr. George Stephenson, from Holyhead, *viâ* Bangor and Chester; it commences at the termini of the Chester and Crewe and the Chester and Birkenhead Railways at Chester, and proceeds by Bangor over the Menai Bridge to Holyhead. The line is 85 miles long, and has only 1,504 yards of tunnel; the gradients appear to be very favourable, viz.

	Miles.	Chains.
Level	41	8
5 feet per mile and under	8	0
Above 5 feet and up to 10 feet	7	20
Above 10 feet and up to 15 feet	20	61
16 feet per mile	7	0
19 feet per mile	0	68
	85	0

That part of the report which relates to the crossing of the Menai Bridge, we have selected and given in full.

Passage of the Menai Bridge.—The passage of the Menai Bridge is the next point of importance. It has been supposed that this would have presented an insuperable obstacle to the lines of Messrs. Stephenson and Giles; but neither of these gentlemen propose to cross the bridge with locomotive engines, the former suggesting that the railway carriages may be drawn over by horses, and the latter by a stationary engine.

There seems to be no objection to either of these plans, and the loss of time consequent upon them would probably not exceed one-quarter of an hour.

The following observations will show the sufficiency of the Menai Bridge to sustain the weight of any number of railway carriages that may be required to pass over it.

In the first place, as far as regards the mode of passage, no important difficulty can be foreseen; the only question, therefore, is one of strength.

The weight of a railway passenger-carriage, with its load, is commonly estimated at about five tons, and the length occupied by each carriage, from one connecting pin to another, may be taken at 22 feet, when several carriages are in connexion. This would give a pressure of only ·23 of a ton per lineal foot on the length of the bridge, supposing the platform to be wholly filled with such carriages.

Let us now see what weight the bridge is capable of sustaining.

It appears from the statement of Mr. Provis, who was the resident engineer during the erection of this splendid structure, that the suspended part between the pier consists

		Tons.	cwt.
Of 16 main chains, including connecting plates, screws, bolts, &c.,	weighing	394	5
Of transverse ties	——	3	16¼
And of suspended rods, platform, &c.	——	215	13¾
The total weight being		613	15

The distance between the points of suspension is 579 feet 10½ inches, and the deflection 13 feet. With these data, the tension in terms of the weight may be readily computed, from the properties of the catenary curve; but it will, perhaps, be more satisfactory to derive it from the actual experiments of Mr Rhodes, who superintended the erection of the chains, and who found, practically, the tension to amount to 1·7 times the weight. This makes the tension on the supporting chains from the weight of the structure alone to amount to 1,094 tons.

Now to sustain this tension, we have a sectional area in the 16 chains of 260 square inches, which, according to Mr. Barlow's experiments, made on the chain-cable testing machine at Woolwich, are capable of sustaining 2,600 tons, without injury to the elastic force of the iron, namely, 10 tons per square inch, the ultimate strength being 25 tons per square inch.

If, then, from the absolute strength of the chains	2,600 tons.
We deduct the strain due to the weight of the bridge	1,094
There remains a surplus of strength of	1,506 tons.

which is competent, therefore, to sustain a uniform load (allowing the tension to be 1·7 times the weight) of $\frac{1506}{1 \cdot 7}$ or 886 tons. Now if the bridge were covered with loaded railway carriages on both sides, it would only be equivalent to 265 tons, leaving still a surplus strength of 621 tons. The objections, therefore, that have been raised respecting the capability of the bridge to bear the weight of the railway carriages which it might be required to support must be considered as utterly groundless.

Mr. Stephenson proposes to establish a station at each end of the bridge, where the locomotive engines would be kept in readiness to be attached to the trains.

DESIGNS FOR THE NEW ASSIZE COURTS, LIVERPOOL.

[We have received several communications respecting the decision of the Committee, and our attention has also been drawn to a letter which appeared in the Liverpool "Albion": it contains a general description of the successful design of Mr. Elmes, and some very appropriate remarks; we therefore give the article entire, with which we hope our correspondents will be satisfied, instead of publishing their papers, as we are so pre-occupied with matter, that we can ill spare the space for any additional remarks; however, we shall be glad to receive any other communication on the subject that may throw some light on the proceedings, in order that we may be able to make some comments on the conduct of the Committee in the next month's Journal, if found necessary.]

Sir—A plan has been pretty generally adopted, of late years, in respect of obtaining designs for public edifices. I mean that of advertising for competition drawings, and awarding one or more prizes, in the ratio of their excellence or fitness, with the implied certainty, that the bearer of the first prize should have still more substantial reward, in the superintendency of the erection of the future edifice. This, in itself, would appear, and perhaps is, the best method that, under the circumstances, could be adopted. It might be difficult to point out a better; but, Sir, a little reflection will at once show, that, however excellent this may be, in the abstract, it entirely loses that character unless it be invariably coupled with the necessary qualifications for judging, combined with excellent taste, in the *awarders* of the honours.

I have held this opinion, in common with others who have given the matter consideration, since the plan became general; but, whatever confirmation it might have then required, the award in the proposed Assize Courts has now amply confirmed. When I say, that the sub-committee, in this case, had *not* the necessary qualifications to fit them for deciding, let it not be understood, that this is done through any feeling of disappointment or personal hostility to gentlemen with some of whom I am on terms of intimacy: on the contrary, I trust I shall be able to prove the position with which I set out to the satisfaction of your readers; but I may, at once, say, that I am not an architect, the truth of which is *known to you*, therefore have not competed for the prize, consequently am not a "disappointed man" individually; but, perhaps, as one of the public, this feeling is particularly strong, and more especially so when I look around the walls of the Exhibition-room, in Postoffice-place. I am not only disappointed, Sir, with the prize-drawings there to be seen, but, with one or two exceptions, the whole. They evidence want of invention, in the first place, and want of judgment, in the second; and the two designs that combine these essentials, have, for want of judgment in the committee, been thrust aside. The majority of the designs, prizes included, evince a servile imitation of the Greek style of temple architecture, which, every day's experience teaches us, is neither fitted to our wants nor our climate. If the Greeks had had either the one or the other, they would have invented a style to have suited both; but invention with us is at once crushed, the ambitious aspirant is unceremoniously thrust out of the arena of competition, and all for want of the necessary qualifications in the awarders of patronage.

In proof of this, I shall, at once, draw your attention to the plans to which the first prize has been awarded, those of Mr. Elmes. By a narrow inspection of these, it will appear very evident the Committee were incompetent to the task allotted them.

In Mr. Elmes' perspective drawing we have a very pretty picture, exquisitely drawn, showing the Railway terminus, on the one hand, and the Assize Courts, on the other, with St. George's-hall occupying a prominent feature in the centre. With this picture, it is very obvious, the Committee have been misled. It is a most successful deception. Now for the proof. The height of St. George's-hall is about eighty-five feet. The fall of the ground, in the direction of the Courts, is twenty-seven feet. The height of the Courts at the lowest end is seventy-six feet. There should, therefore, be shown, *in the drawings*, a difference of thirty-six feet in their relative heights; but, as the Courts do not come quite to the extremity of the fall, say thirty-two feet. This difference, however, is most dexterously evaded, and leaves us to imagine the Courts and St. George's-hall will be, to a spectator in the foreground, very nearly of one height. But this is not all. In this height of seventy-six feet is included a dead wall, rising fifteen feet above the parapet of the colonnade. This wall is so much set *back* from the front that it could not be seen except at a considerable distance from the building. This, in effect, would rob it of fifteen feet more, which, added to the thirty-two feet above, gives us forty-seven feet, or, in other words, taking as much height from it, within three feet, as goes to a five-story warehouse. Let it be understood, this is in relation to St. George's-hall; but, in relation to itself, this dead wall would, practically, reduce the height of the building to sixty-two feet, making the visual difference between the Courts and St. George's-hall about fifty feet.

The perspective drawing, however, does not, in the slightest degree, convey this difference; but, in execution, this would be necessarily exhibited. Another example. The stylobate, at the southwest corner, is shown only six feet six inches high, whereas the *real* height is about thirteen feet. Moreover, windows are shown in the plans, which are omitted in the elevation; but, had they been shown, they would have spoiled the effect of the picture.

More examples of this nature might be adduced, but let us come to the interior arrangements, for, after all, these are, by far, the most important parts to be taken into consideration; but, it is very evident, Mr. Elmes calculated on the incompetency of the Committee to measure his perspective drawing and compare it with his plans. The event shows he was right. This gentleman, in the document attached to his plans, asserts, that he has complied with the printed instructions, and that every apartment contains the full number of square yards required by them. His designs, however, show he has exceeded the limits by thirty-six feet in the length of the building, but this is concealed in the plan, and is only to be detected by carefully examining the section. His Courts fall considerably short of the areas required, which were 290 square yards for the Crown Court, and 320 for the Civil Court; but the space given by Mr. Elmes is 231 yards for the former and 264⅓ yards for the latter, making a deficiency of 59 square yards for the one and 55⅔ for the other, making a total deficiency of 114 square yards out of 610; but there are two lobbies at the end of the Courts, situated behind some columns, which, if he mean to include, would leave a deficiency of 74⅓ square yards. From this, it is very clear, the prize was not awarded Mr. Elmes for strict adherence to instructions, although he deliberately says he has done so.

Let us now take a glance at the arrangements for the transaction of the business of the Courts. The counsel have to ascend 30 feet to their robing-rooms, and then to descend 26 feet into court in their wigs and gowns. The jury of the Crown Court have allotted them a small room, 15 feet by 10 feet, and for the Civil Court, one, 17 feet 6 inches by 9 feet 6 inches, neither of them possessing a water-closet: this last omission, no doubt, is intentional, —nothiog on earth like it to bring obstinate men to a prompt decision.

The clerk of the indictments'-room is situated 30 feet *above* the ground floor. The witnesses have to ascend that height from their room, which is on the basement floor, and then to descend to the grand jury-room, situate midway, and, ultimately, to the ground floor into court. The most casual observer must, at once, perceive this to be the worst possible arrangement. The floor of the judge's bench is 6 feet 6 inches above the floor of the court, which is just twice the height it should be. The semicircular form of the courts is objectionable, from the irregular reverberation of sound proceeding from a curved surface. This has been so fully proved in other buildings similarly constructed, that various expedients have been adopted to abate the evil.

Another most important point, the lighting of the interior apartments, is really bad. He has resorted to the most clumsy and awkward expedients, and all to render darkness visible. The judges enter a vestibule totally dark; and the attorneys, barristers, &c. could not recognise one another in the corridors allotted to them. In short, the general interior arrangements are exceedingly ill contrived, being so disconnected by having four different storeys, beside the one containing the gaol arrangements, while in no case ought it to have exceeded two.

Now, Sir, for a word or two on the architectural composition of the exterior. My opinion is, that, in execution, it would prove a complete failure, and disappoint those who have been *caught* by the pictorial effect of the drawings.

The east, or principal, façade is badly arranged. The portico, contrary to the rules of architecture, and I may add a still greater authority, good taste, is denuded of the most essential element of grandeur and beauty; I mean a noble flight of steps ascending to it: instead of which it is placed on a mural stylobate, having an insignificant door stuck in its centre, as if by accident, or as if the architect had originally forgotten to provide his principal entrance.

The colonnade on either side the portico ought to have been full and uninterrupted in its whole extent: instead of which, it is divided into three parts, with pilastered blocks of masonry, each eighteen feet wide. This, in execution, would totally destroy that simple unity which ought to characterize that style of architecture the artist himself has chosen. This defect does not strike the observer in the picture, in consequence of the admirable *management* of the lights; but, in the actual structure, this would be most unsightly and offensive to good taste. Not satisfied with this violation, he has placed a line of dead wall, fifteen feet high, above the broken line of columns beneath, which, in effect, would appear to crush it, when seen from a distance. This ungraceful method of acquiring height has, I have observed, invariably destroyed the effect of other buildings where it has been resorted to. I could point out a much greater number of defects; but, at best, it is a most ungracious task: however, it is better to do so now than allow the building to be quietly erected with all its faults, and then cavil when it is too late to apply the remedy. Upon the whole, I consider the decision of the Committee to be altogether an erroneous one, because, if we put the architectural beauty out of the question, the interior arrangements will require to be entirely remodelled to adapt them to the purposes for which they are intended.

It would take too much time to point out what arrangements really should have been made; but here are a few omissions.

Mr. Elmes has no magistrates'-room, nor a room for the high-sheriff; he has also omitted the court-keepers' apartments and has not shown *cells for prisoners;* he has no room for attorneys consulting apart with a prisoner, neither has he any room where a prisoner can see his friends on obtaining a judge's order. The room he has appropriated for counsel is only twenty-six feet by seventeen feet six inches, and this is to accommodate upwards of 200 barristers, and this number, with the increasing business of the courts, is sure to be greater. In fact, the room in the present courts devoted to this purpose is much larger.

It might be asked, if so much is abridged and omitted, what has become of the space, seeing that the plans exceed the given amount? I answer, it is absorbed in large galleries, to accommodate the public attending the Crown Court. This is plausible, no doubt; but what is the practical result? That the morbid taste of that portion of the community who delight in accounts of murder, rape, and robbery will be amply gratified; while the other portion of the public attending the Civil Court have but small accommodation. Experience has sufficiently shown us, that the disgusting details of criminal courts act more by way of *precept* than example on the auditory who frequent them.

In fact, throughout the interior arrangements there is an utter absence of that knowledge of the business of courts which is indispensible to their proper arrangement. Apartments that, according to the practice of law courts, should be together are placed on different storeys, occasionally on opposite sides of the building; hence would accrue a continual travelling up and down stairs, and traversing long dark passages, when, with proper arrangement, all these annoyances might have been avoided.

I think, after this, you must agree with me, Sir, that the Committee have been misled by the beauty of Mr. Elmes's drawings, which, after all, do himself, or the artist he employed, great credit.

Seeing, through the medium of your paper, that a memorial was presented, on this subject, to Council, by two of our resident architects, Messrs. Cunningham and Holme, I have been, in consequence, induced to give their designs a more minute examination.

Their second design, I mean the one with the towers, having a magnificent portico, with a flight of steps leading up to it. This building would have been a real ornament to the town. It combines many desiderata for the promotion of architectural effect; but the towers alone are worthy of Martin. Had they been executed, they would have formed a most prominent architectural feature in the eye of strangers visiting us. I have not studied their design with a view to minute criticism. Had they received the first prize, it is highly probable they would not have been let off so easily: however, there is, at once, boldness and novelty in the conception of their plans, which bias me very much in their favour. As to the interior arrangements proposed by these gentlemen, they are very much superior to Mr. Elmes's. They seem to have forgotten nothing, but have rendered the edifice, as a whole, entirely subservient to the purpose of the courts. Yet, if I recollect aright, these gentlemen's designs were, at once, placed *hors de combat*.

In their memorial they complained that their plans had been set aside, on the alleged ground of having exceeded the limits pointed out in the instructions; while, on the other hand, the plans to which the prize *was awarded* had, in a similar manner, also very much departed from them. Notwithstanding which, they were not only allowed to retain their place among the final ten, but actually carried off the prize! Now, Sir, I cannot help thinking they had just right of complaint. But how was it met by the Committee, in the person of the Town Surveyor? At first is was denied, and *then* admitted, that is, "*if* the *porticos* were meant to be *included*"! This last, Sir, is the crowning joke of the whole. Hamlet, with the *principal* character omitted, is a fool to it. "If the porticos were meant to be included in the measurement"? Only think. Suppose your office is in want of a devil, you advertise for one, his mother applies, (if devils have mothers,) you want to know his height. The lady replies, "Four feet six." You object to this as being too small, when you are met with the *after thought*, that that is his height as far as his shoulders only; but, then, he is a *head* taller still, if you mean to include that most unimportant portion of his corpus. Of such a nature was our surveyor's answer to Messrs. Cunningham and Holme's objection. The porticos being, I need scarcely say, "the very heads and fronts" of the building.

In conclusion, Sir, I may add, that my only motive, in this letter, is, my duty as a burgess, and a love of having my visual organs gratified by beautiful architectural objects, in my walks through our flourishing good old town.

I am, an old correspondent,

ONE OF THE PEOPLE.

Liverpool, May 14th.

EXTRACTS FROM THE LOG OF THE ARCHIMEDES.

First Day, April 21.—Light breezes from Northward. A.M. 7·30, left Dover Roads with H.M.S. Ariel for Calais. Archimedes rather leading. At 8·45 both vessels made sail, with light wind from S.W. At 10, Ariel one mile astern, and sail shortened. 10·23, abreast of Calais—beating Ariel by six minutes.

Second Day, April 22.—A.M. 1·10, left Calais with the Ariel—wind W.S.W. and fresher than on the preceding day: Ariel rather gaining, but on sail being set on both vessels, Archimedes came in first by five minutes. Close hauled the whole distance, and rate with sail and steam 9¾. Time of arrival in Dover Roads, 6·42 A.M. A.M. 8·30, the same morning, left Dover Roads with H.M. Packet Beaver—light winds from S.W. 9·20, one length a-head of Beaver. 9·45, three lengths a-head of Beaver—rate 9½ knots—engine making 27 strokes per minute—barometer 26 inches. 10·45, 2½ cables length a-head of Beaver. 11·30, Beaver made sail. Noon—light breezes from S.W. Beaver two-thirds of a mile astern. At 4·53 P.M. arrived in Ostend Roads, beating Beaver by four minutes.

Third Day, April 23.—Topmasts struck, and gaffs down, wind W.—A.M. 9. Followed in Beaver's wake through the Channel. At 10, going 9¼ knots—Beaver a-head one-third of a mile. 11·30, abreast of Dunkirk. At noon—moderate breezes from W.N.W.—Beaver one mile a-head—Strokes 26—rate 8¾ knots. P.M. 2, made sail—Beaver 1½ mile a-head—9¼ knots. At 4h. 28m. 30s. Beaver a-breast of Dover Pier.—4h. 37m. 30s. Archimedes ditto.—Nine minutes in favour of Beaver.

Fourth Day, April 25.—A.M. 8·13, started a-breast of each other with H.M. Packets Beaver and Ariel—light breezes from E. by N.—rate 9½ knots—barometer 26 inches—strokes 27. Beaver arrived first in Calais Roads by 2 minutes 45 seconds—Ariel second, not quite three lengths a-head of Archimedes. 11·25, left Calais Roads in search of H.M.S. Swallow, with the Ostend mails. P.M. 1·28, abreast of Swallow. 2·52, abreast of Dover Pier, Swallow about two lengths astern—no sail set all this day.

Fifth Day April 27.—A.M. 6·40, started with the Britannia Steamer for Boulogne, she being half a mile a-head. At 7, on her beam—rate 9½ knots—Britannia made sail. At 7·15, made sail also—moderate breezes from the N.E.—course South—10 knots—27 strokes—barometer 26 inches. At 9h. 2m. 15s. rounded the buoy off Boulogne Pier. At 9h. 49m. Britannia passed the buoy. Difference of time 21m. 15s.—of distance about 3¾ miles. P.M. 1·52, made sail for Dover—fresh breezes from N.E.—sailing and steaming, close hauled, 9½ knots, clear full, 10 knots. At 4, the wind being fresh and dead a-head, took in sail—steaming, 8¾ knots. At 5·19, off Dover Pier—having made the passage, under the above circumstances, and *against an ebb tide*, in 3h. 27m.

Sixth Day, April 28.—On this day, Capt. Chappell, R.N., and Mr. Lloyd, Engineer from H. M. Dock Yard at Woolwich, commenced the superintendence of the trials, having been sent down specially by the Lords Commissioners of the Admiralty to report thereon. A.M. 8·45, left Dover Roads with H.M.S. Widgeon—moderate breezes, wind E. by N.—rate 8½ knots—for Dungeness light, distance 19 nautical miles. Widgeon first by 5m. 30s. In returning, against a head wind—rate, 8 and 7¾—strokes, 26 per minute. Widgeon beat by exactly 10 minutes. No sail set this day. Widgeon is the fastest of the Dover packets, her engines being of 90 horse power; her power is thus 10 horses greater than the Archimedes, while her tonnage is 80 tons less. Most of the Dover packets are of 70 horse power: they are, on an average, about 90 tons smaller, draw 4½ feet less water, and are not so broad by 5 feet. During the whole of these trials the sea has been perfectly smooth, and no opportunity has hitherto occurred of displaying the peculiar advantage of the Screw over the Paddle Wheels in a rough sea and a strong wind. Since the above was written—in a run to Calais, in a dead calm, Widgeon beat Archimedes by only 2½ minutes in going, and 4 minutes in returning:—Time in going over, 2h. 9m; returning, 2h. 11m.

The French Government Steamer, La Poste, was beaten on this occasion 25 minutes. She is about 135 tons, and her engines of 50 horse power.

On the 1st of May, the Widgeon and Archimedes started together for Calais, with a moderate breeze, both carrying sail and steaming.—Archimedes performed the distance to Calais Roads in 2h. 1m., beating Widgeon by 9 minutes. In returning to Dover, she beat the Widgeon by 5 minutes, making the distance in 1h. 53m., the fastest passage EVER made between France and England by 14 minutes.

[To render these experiments complete, the quantity of fuel consumed in each trip and by each vessel should be ascertained.—EDITOR.]

NEW ROYAL EXCHANGE.

THE Gresham Committee met on the 7th ult., to decide on the two plans for the Royal Exchange submitted to the Committee by Mr. Cockerell, R.A., and Mr. Tite, President of the Architectural Society, and after a protracted discussion, the Committee finally determined in favour of Mr. Tite by 13 votes to 7. The building will now be proceeded with without delay. The following description of the design appeared in the daily papers:—

The design thus adopted possesses features of a very striking character, and is much approved of in the city. It will be recollected that the site of the intended building is of an irregular form. The ground westward of this site is to be cleared by the removal of the two masses of building which now stand in front of the Bank, so as to leave an uninterrupted area from the intersection of the streets in front of the Mansion-house; in this area it is intended to place the statue of the Duke of Wellington. From the nature of the ground, any form of building which should adequately occupy it, must be much wider at the east end than at the west. This irregularity is concealed, and, though not rectangular, the proposed structure is perfectly regular in the plan.

At the west end, the architect has placed a very striking portico of eight columns of the Corinthian order. The width of this portico is 90 feet, and its height to the apex of the pediment 75 feet; this is 16 feet wider and 17 feet higher than the portico of the church of St. Martin-in-the-Fields. Behind the portico is the central entrance to the Exchange, which is deeply recessed within a large arched opening, having on each side an arch of corresponding general character. When clear of the portico, the building is increased in width by pilasters and recesses, making its greatest extent at the west end 106 feet.

The south front, or that towards Cornhill, is an unbroken line of 250 feet, occupied by a range of Corinthian pilasters, the intervals between which are divided in height into two stories. The lower of these consists of a series of rusticated arches, which comprises the shops, and the entrances both to the Exchange and the offices; the upper story includes a uniform line of decorated windows for the principal floor.

The north front is generally similar to the south.

The east front is terminated at its northern and southern extremities by curved corners, each containing three rusticated arches, with windows above; and from the centre of this front rises a tower 160 feet in height, terminated by a vane, formed of the ancient grasshopper, the crest of Sir T. Gresham.

The total length of the building, including the projection of the portico, is 293 feet, and its extreme width at the east end is 175 feet.

The area for the merchants is nearly in the centre of the edifice. It is a parallelogram, 170 feet in length from east to west, by 112 feet from north to south, and is entered in the centre of each of the four side. There is a colonnade of the Doric order round this area, which leaves about one-third of the whole space open. Over the colonnade is a second order of attached Ionic columns, with arched and highly decorated windows in each intercolumniation.

With reference to the arrangements of the plan, it appears that the ground floor is principally appropriated to shops and offices, except a part of the north-east corner, which is given to Lloyd's, and the south-west, which is reserved for the Royal Exchange Assurance-office. On the one pair, or principal floor, the Subscribers'-room, Commercial-room, Reading-room, and other apartments of Lloyd's, occupy the whole of the eastern portion of the building, and about two-thirds of the northern. The Gresham Lecture-rooms, library, and other apartments, fill up the rest of the north front and part of the west. The south front, in nearly all its length, is given to the corporation of the London Assurance, which establishment is to be accommodated in the new building; and the remainder of the south and west is appropriated to the Royal Exchange Assurance.

THE METROPOLITAN WATER SUPPLY.

TABLE shewing the foreign matters contained in one gallon of *Thames water*, taken from different parts of the river, and of the same quantity of the water from the *Valley of the Colne*.—(See Minutes of Evidence, 1840, p. 19.)

Thames water.	Carbonate of lime.	Sulphate of lime and common salt.	Total in 1 gallon.
	Grains.	Grains.	Grains.
From near Brentford	16	3·4	19·4
From near Hammersmith	16·9	1·7	18·6
From near Chelsea	16·5	2·9	19·4
Sources of the proposed London and Westminster Water Company.			
From Otterspool (main spring)	18·8	2·5	21·3
From main stream (Valley of the Colne)	19·3	2·5	21·8
From the river Colne	18·1	3·2	21·3

Besides the above, the Thames water, as well as that from the Valley of the Colne, was found to contain a very minute portion of oxide of iron, silica, magnesia, and carbonaceous matter.

[We were not prepared to find that the water from the Otterspool spring, flowing through chalk, contained such a minute quantity of carbonate of lime as 2 grains in 70,000 grains, (the weight of a gallon of water), more than water of the river Thames. To us this appears to be a very satisfactory result in favour of the proposed new Company.—EDITOR.]

SUSPENSION BRIDGES.

WITH AN ENGRAVING, PLATE X.

Lord Western's Letter to Lord Melbourne, descriptive of a Suspension Bridge built across the Avon, at Bath, by Mr. Dredge, *a resident of that city, upon an entirely novel principle.*

My dear Lord,—Having heard that Government is about to expend a further sum of money on the reparation of the Menai Bridge, which is said to be in a perilous state, I cannot refrain from entreating your attention to the vast improvement that has been made in the construction of suspension bridges by Mr. Dredge, of Bath. During a recent residence of two months in that city, I have had an opportunity of seeing often the bridge that has been built by him across the Avon; it is a beautiful structure, and at once commands admiration of its beauty and confidence, in its stability; I have communicated with him frequently about it, and altogether the consequence has been so strong an impression upon my mind of the vast and immeasurable superiority of the principle on which it is built over anything that has hitherto been attempted, that I have been led into this somewhat extraordinary intrusion upon your Lordship on a matter with which I may be, I own, justly considered to have no very intimate or scientific acquaintance; such however is the simplicity of the work, that I will not hesitate to attempt some account and explanation of it, in the hope of drawing your attention in the first instance, which, if I accomplish, you will be led, I think, to give it a closer examination, which will produce eventually as strong a conviction in its favour on your mind as it has produced upon mine.

Mr. Dredge's statements of the superiority of the power of his system over the established plan of structure certainly at first astonished me; he has indeed proved by trials, in the presence of very many persons, a superiority of strength to the extent of at least 150 per cent. These were made upon small models of bridges formed severally on the present and on his new principles, each out of the same quantity of iron, but he carries his calculations of the accumulating power derivable from size and extent over and above the 150 per cent. shown upon the small models to such a degree, that I will not venture to state it; but if he should be called upon, in the way I trust sooner or later he will be, to exhibit his system before your Lordship and the public, he is confident he can mathematically and practically establish any of the statements he may make, and I have little doubt he will be found to be correct. He insists on the possibility of reconstructing the iron work of the Menai-bridge at a less sum than the superfluous iron would sell for, so much less is requisite than was there used, and he pledges himself to the power of the bridge, if the irons are altogether altered and reconstructed on his principle to be capable of supporting on transit 1,000 tons. The Menai-bridge is believed to have cost near 150,000*l.*, and to have consumed in its construction above 2,000 tons of iron, and to be declared only capable of sustaining 733 tons on transit. Before I submit to your Lordship a detail of some practical experiments Mr. Dredge has made justificatory of the declarations he thus ventures to put forth, I will endeavour to give some explanation, imperfect though I am sensible it must be, of the fundamental principle upon which his mighty fabric is erected; I must give it merely as it has struck my unlearned common sense, and which it has, from its simplicity, with a force so irresistible that it makes me believe I fully understand it; in aid of my endeavour I have given a few drawings on an annexed sheet. I conceive the grand foundation may be said to be the rendering the chains strongest and indeed very much the strongest at the base, tapering them by regular degrees to the centre, where they come at last, in fact, to a cipher, from the cipher commence therefore their size, weight, and strength, which regularly increase by degrees quite up to its base, which base you know in a suspension bridge is the towers of masonry on which the chains are hung; in truth, it is the application of that principle horizontally which is so obviously necessary in all perpendicular erections, of superior size and strength at the base, and tapering away to a cipher on its ultimate summit; as for example the obelisk, the pyramid, the church spire, and which principle he shows to be as effective horizontally applied as it is in the perpendicular; indeed, it may be said to be far more effective, as it has to support in so difficult a position, comparatively with the perpendicular, its own intrinsic weight, and a heavy transit load besides. The manner in which the chains of his bridge are formed to render them stronger at the base is shown in plate, Fig. 2; and Fig. 4 is a section of one of the main chain of the Menai-bridge; these are the same size throughout, creating thereby an enormous intrinsic and superfluous weight, exceeding that which it has to sustain on transit, and this it is which constitutes the grand vice of the present system, and which sooner or later Mr. Dredge's must supersede. Mr. Dredge's bridge may be well imagined by supposing a church spire laid horizontally, and met by another of equal dimensions at the point, as represented at Fig. 8.

There is another figure by which the principle may be more clearly shown; it is the bracket; two brackets meeting at their extreme points give a very satisfactory idea of it, as in plate, Fig. 9. Every body knows that the bracket tapering from its base will bear horizontally a great weight, but if it was the same size from the base to its extremity, though it might continue to be called a bracket, it would hardly sustain itself if it was any considerable length.* I have to remark now upon another most important peculiarity in Mr. Dredge's bridge, and that is the diagonal direction of the road suspending rods, instead of perpendicular, and forming, therefore, as it unquestionably does, a powerful contributary effect to the support of the whole, and this is also most easily capable of direct practical proof. There is still a further point of difference and advantage in Mr. Dredge's bridge, which appears to me to be equally simple and as proveable, and which also essentially contributes to increase its aggregate power and security—that is, its horizontal action or pressure, which is also made obvious by a simple and familiar figure representing one half of a bridge: suppose a straight rod of any given length, fasten a cord at one end of it, and thence to the top of a wall, place the other end to that at which the cord or chain is fastened against the wall, at such a distance below the top of the wall as will render the position of the rod horizontal, and it must be plainly seen that the rod is supported as well by its compression against the wall at one end, as by its cord of suspension at the other, see Fig. 10. Thus every component part of the structure is brought harmoniously to work and in perfect unity of action towards the grand object. I will now advert again to the Menai-bridge, and show further in essential points the difference between that and indeed most other suspension bridges, and Mr. Dredge's. The actual intrinsic strain at the centre of the Menai-bridge according to "*Drewry*," page 167, amounts to 1,878 tons, and at each extremity 1,913 tons. This vast intrinsic weight operates its own destruction, increasing its self-destructive power as it increases in length; thus it becomes vibratory, and upon a gale of wind blowing upon its broadside, it has a swing or pendulous motion; this I have felt myself in passing it, the wind blowing strong at the time.

On the other hand, as I have observed before, upon Mr. Dredge's principle, the strain and weight only commence at the centre, increasing as the strength of the bridge increases up to the base, and of course its ability to sustain it; this difference between these two systems may be readily imagined. By supposing a ton of iron formed into a bar of equal dimensions from one end to the other, as is shown in Fig. 7, and fixed into a wall, it will hardly support itself, still less any additional load; if extended to any considerable length it will not support itself; on the other hand, make the same weight of iron into a taper form, as in Fig. 6, and it will support its own weight to any extent, and a heavy extrinsic weight in addition; but further than this, if the parallel equal-sized bar is cut away by one-half, (see dotted line in Fig. 7,) it will then support itself and an extrinsic weight in addition. The reason is obvious; it has discharged itself of that which was altogether superfluous and therefore noxious in the extreme, being wholly destructive of power to carry any extrinsic weight. In this figure is a singularly accurate exemplification of the vice of the Menai-bridge, and others built upon the same principle, and the obvious good sense of Mr. Dredge's. Thus his genius has led him, by the simplicity and perspicuity of his conceptions, to effect a discovery which, I firmly believe, will turn out of great national importance, the recognition of which by the country will, I am sure, be felt by him as the highest possible reward. Having thus endeavoured to show the simple principle on which Mr. Dredge's system is founded, I proceed to give you some account of some experiments he has made practically substantiating the truth of it, prefacing them, however, with a brief description of the expense and particulars of the Victoria bridge across the Avon, built in 1836, and which has proved itself equal to its inventor's most sanguine expectations; its cost was 1,650*l.*, its span is 150 feet, and only 21 tons of iron were consumed in its construction, which, at 20*l.* per ton, is only 420*l.*; the great expense, therefore, was on the masonry and the timbers supporting the plat-

* It may be remarked that there is not a strict similarity between the common bracket and the bridge, inasmuch as the platform or horizontal line is, in the former, above and in the latter, below; there is, however, no real difference. The power of the bracket is compounded of suspension and compression, that is, suspension from the fulcrum, and compression against the fulcrum. In the case of the common bracket, the horizontal line which is uppermost, being fixed or fastened securely to the fulcrum, performs the suspension part of the work, the arch or diagonal line below the compression, attaching itself to the fulcrum without fastening; the case of the bridge is, however, only so far different, that the arched line does the suspension part, and the horizontal the compression.

of wire, their spans were 4 ft. 6 in., their deflections 6 inches, and their platforms were 2 feet. The parallel chain model (old system) broke down on putting six sacks of beans on its platform, weighing about 13 cwt: the taper chain model (new system) bore the six sacks of beans, seven sacks of malt, weighing 10 cwt., 2 cwt. of iron, and 11 men at the same time, all of which did not break it down. In Bristol, Jan. 6, 1838, before Messrs. Protheroe, Guppy, and others, two other models of equal materials and dimensions were tried. The parallel chain model bore 1,565 lb.; the taper model bore 3,684 lb. Again, in Bristol, January 10, 1838, more trials were made before Messrs. Acraman, Daniels, Hillhouse, and many others of the first merchants of Bristol, Dr. Waldron, and many others of Bath, with models of equal material; the parallel chains bore 1,156 lb.; the taper chains bore 3,696 lb. Another trial before the same party on the same day was made with models constructed by Mr. Cross, of Bristol, unknown to Mr. Dredge, in order to prove that all was fair in the former trials; the result was, the parallel chains bore 2,632 lb., and the taper chains bore 6,849 lb. Each model broke on adding more weight, and the wire throughout on the taper principle was reduced one size by the experiments.

Now, my Lord, all I request is, in the event of further repairs or improvements being about to be undertaken of the Menai bridge, that you will allow Mr. Dredge to exhibit some similar experiments before your lordship or the Treasury, or before the Bridge Commissioners, and in the presence of any of the most eminent engineers you may choose to summon. Finally, my lord, Mr. Dredge declares that such is his thorough conviction of the truth of his theory, and its facility of execution, that he would gladly undertake, at his own expense and risk, *the whole of the iron work*, if he should be allowed to reconstruct it, which he believes he could do, the bridge standing all the time, and that it should be competent to sustain 1000 tons on transit; the superfluous iron of the present bridge he is pretty confident would pay him, and give a balance in favour of Government.

Questions may, after all, fairly be put to me to learn why, with all these advantages of Mr. Dredge's system, exhibited with so much apparent fairness, has not his principle been at once generally acted upon? Why has he not been called upon in many cases to execute what he thus promises? Why, if he can build the proposed Clifton bridge, as he says he could, for one-third or less than Mr. Brunel's estimate, is he not called upon to do so? One good reason is obvious —a prudent caution on the part of the public disinclines them to overthrow long-established systems, and to oppose or even question the judgment of long known and respected authorities: this feeling operates very naturally and happily in philosophy as well as in politics; but it should not in either be carried to the extent of checking the progress of improvement by well-considered means; too great a tenacity for old systems may exist in the minds of many persons, though their motives may be good and their minds not illiberal; Mr. Dredge's principle of suspension bridge building completely overthrows the theory and practice of a Telford, a Brunel, whose experience and talents we are bound highly to respect, and to whose genius I readily offer the humble tribute of my admiration; can we then be surprised that the public should evince some fear, and some reluctance, hastily to adopt Mr. Dredge's novel principle or theory, in substitution of that which has been so long acted upon? They ought, therefore to pause, they ought to inquire if there are any persons about to direct the construction of other suspension bridges; it is a duty they owe to those for whom they may be acting, to examine fully into the merits of a novel system which *promises fairly* such advantages, before they determine to persist in the further adoption of the present, of the correctness of which the state of the Menai bridge, and the vast expenditure it occasions, may well create a doubt, independent of the obviously faulty principles on which it is, I think, clearly shown to be constructed. No human being was ever exempt from error, and Messrs. Telford, Brunel, and others, must not be considered to be infallible. I have only to add, my dear lord, that in making this address to you, I have no other motive than the desire of assisting to bring forward genius, and secure for the country the benefit of a most valuable discovery and work of art, which appears to me, for want of form or road, which are still of insufficient dimensions and strength, but which, of course, are quite unconnected with the principle on which the bridge is built; the chains are under 10 tons, and are equal to sustain 500 tons on transit. In November he began putting the chains of this bridge together, and in the following month it was opened for general use; its road is stoned like common roads. In further proof of the correctness of this system, tests have been made before various parties at various times, viz., at Bath, January 2, 1838, before Messrs. Worsams from London, Ball of Cambridge, and others of Bath, with models whose lengths, deflections, and weight were equal, the chains of each model between the fulcrums were only 9 oz. that encouragement which I think it merits, to be in danger, like very many others, of being lost sight of altogether.

I have the honour to be, my dear lord,
Your faithful and obedient servant,
To the Viscount Melbourne. WESTERN.

P.S. Your lordship will of course understand that I entertain no idea of expecting or asking anything more of your lordship, than a reference of Mr. Dredge to the proper departments, with a recommendation to give his plan of improvement due attention and consideration, should Government be under the necessity of engaging in further expense upon the Menai bridge.

[At the Adelaide Gallery on the 19th ultimo, Mr. Dredge explained the principles of his patent suspension chain bridge, and performed some experiments in the presence of several gentlemen to show the relative merit of his suspension chain in comparison with one on the ordinary construction. He had made two models of suspension bridges, each 5 feet 8½ inches long, and with chains of 8½ inches deflection—the first experiment was with a model constructed with two chains on the ordinary principle, each consisting of 3 wires laid parallel to each other as in fig 4, to which by the aid of vertical wires as in fig. 5, a platform of wood was suspended, this platform was loaded with 7 full grown persons, and upon the eighth getting on, it broke down. The wire chains were fractured at the point of suspension. The weight of the wire in this model was 6½ ounces. The next experiment was with two wire chains consisting of six wires at the point of suspension, and diminishing off to one in the centre similar to fig. 2, these chains supported by suspension wires placed obliquely as shown in figs. 1 and 3, the platform which was loaded with 11 persons, without producing any fracture, until one or two of the party stamped on the platform, when it broke down, the fracture taking place at the junction of the oblique wires with the chain of suspension. The weight of the wire in this model was only 6 ounces.—EDITOR.]

EXHIBITIONS OF COMPETITION DRAWINGS.

SIR—In my former letter it did not occur to me to make a suggestion that might possibly be deemed worth consideration, which is, that in exhibitions of competition drawings—supposing they do not take place until after the decision has been made, there should be no disclosure as to which among them have obtained premiums, at least not until a given time has elapsed. The advantages that would attend such a regulation are, I conceive, tolerably obvious, because, not knowing which are the rejected and which the approved designs, the public would then give their attention to all, at any rate to such as appeared to them of most mark and likelihood, without prepossession or bias, whereas, when it is known which are the premiumed drawings, those naturally engross attention, and the rest are looked upon, by the majority of visitors at least, as the doomed, consequently not entitled to admiration. Public opinion would thus be left free from prejudice, prepossession, and prejudgment; consequently there would be a stimulus to diligent examination and scrutiny which does not now exist.

How far such a plan would prove a convenient one for the judges themselves, is a different matter. Probably it would subject them to a severe ordeal, and place them in an awkward situation; for it is my opinion that had not the fact been made known beforehand, no one would ever have suspected that Mr. Railton's and Mr. Grellier's designs obtained the first premium, the one for the Nelson Monument, the other for the Royal Exchange.

However, so far from being made any objection to the course here recommended, that becomes an additional argument in favour of it, because those with whom the power of awarding the premiums rest, would feel a much greater degree of responsibility than they now do, and would accordingly exercise greater caution and scrupulousness, lest they should find themselves in a most disagreeable minority. Those who would not care to submit their judgment to such hazardous ordeal, are but ill qualified for the important office they assume.

I remain, &c.,
Q.

MOVING BEACHES.

"I acknowledge no authority but that of observation."—*Linn.*

The attention of scientific and practical men has for many years been directed to the action of the sea, and tides which give motion to the shingle, and other matter composing the beaches of our island, and this important affair has been a subject of much speculative opinion, but it appears not hitherto to have received that systematic investigation which is essential. Indeed the contrariety of opinion so often expressed on this subject, seems to indicate an absence of a satisfactory mode of inquiry to obtain a practical and safe deduction.

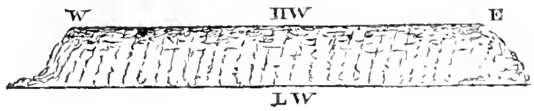
The coast of Kent and Sussex seems to have attracted attention to the subject of the commonly called *travelling beach*, under an erroneous presumption that such occurrences are peculiar to those shores, but experience, the result of practical observation, demonstrates that where nature is placed under similar circumstances, as to her formation, and the operations of the wind, sea, and tides, there she is immutable in her results, and therefore in all parts of the globe, the movement of the beach is the same as is observed on the Dover, or Channel shores; but in *no instance throughout the world has a beach been found to travel along the line from one point to another of a shore or coast.*

We proceed then to prove the egregious error so commonly adopted as to the *travelling* of a beach—divesting our statement of all terms that do not belong to, or which are not generally understood by nautical and other persons that take an interest in this affair.

The flood in the British channel sets in from the westward, and runs with considerable velocity in many parts to the eastward; it is during the time of this flood, with winds blowing from particular points of the compass, that *accumulation* of beach occurs.

The margin of all coasts throughout our globe having *beach forming the line of high and low water mark*, is constantly moving, so as to alter the angle considerably between the two lines. The wave falling on and moving the beach (for there is no movement of the bed of the ocean where the sea does not *break*), takes it up, and deposits it between the high and low water mark, in extraordinary tides and winds, and high seas, simultaneously, and with mathematical accuracy, along a line of beach to the extent of many miles, the largest pebble or shingle, and the greatest quantity, forming the same into a ridge or bank, in a line parallel to the high water mark (Fig. 1.); from the *commencement* of the shingle west, *to its terminus east.* A beach of sand is operated on precisely in the same way, but if the beach travelled in a right line with the coast, from west to east, than would the line of high water beach be on an inclined plane from west to east, and in time a mountain would be formed at the eastern terminus of the *beach.* (Fig.2.)

Fig. 1.



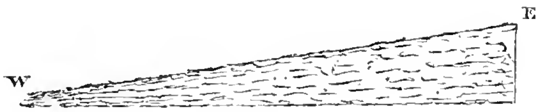


Fig. 2.

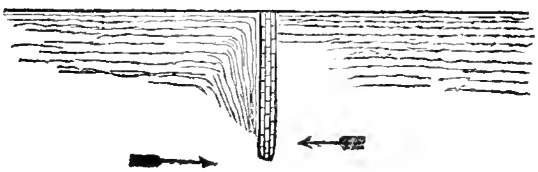
It is correctly stated that a groin or any natural projection beyond the line of coast, intercepting the tide in its passage eastward, would have its *weather*, or to speak nautically, its flood, or western side filled up in the form of a right angle, but that its east, or lee side would be without any extra accumulation, to a certain extent this is quite true; this deficiency is in proportion to the quantity left on the weather side, which but for the projection or groin would of course obtain the quantity so deposited on the west side (Fig. 3.), but at a short distance east of the groin, or on its lee side, the beach assumes its natural form, and the line continues till it meets with another similar interception. So then the only object obtained is an additional accumulation westward, less its amount eastward of the groin, and let it be remembered that this eastern continuation goes on, although the accumulation on the western side of the groin has not filled it up, to its seaward end, and therefore does not pass round it. Beachy Head, Dungeness, the south and north Foreland are all natural groins, but the Bays east of the Head to leeward, the eastern side of Dungeness, the east Bay of Dover, Deal beach, (the *highest of all* modern accumulation, notwithstanding the projection of the south Foreland as A GROIN,) Margate, Herne Bay, &c., all simultaneously accumulate, despite of those extended projections.

Fig. 3.



The fact of the angular formation of the accumulation at the groin, at once proves the direction the beach takes when thrown up by the sea. As the sea, at all *times* during the prevalence of the accumulating tide and wind, falls on the shore at an angle of 45°, so what it lifts up, it throws on in the same direction, but if the beach moved in a right line with the coast, it would fall on, and form at the groin in a like line.

The next practical fact we adduce to disprove the hypothesis of a travelling beach is, that wherever a line of shingle beach is intercepted by chalk, rock, sand, or any other material, of which such part of the coast may be composed, there no pebble or shingle exists. On the rocky shore west of Dover, in which there are many interstices, receptacles for various shell fish, there is no shingle or pebble found in any part of those rocks; if the beach at Dover, &c., came from the westward, it must pass over those rocks, and consequently in its transit some would be deposited in the holes of the rock—but it is not so.

Captain Martin of Ramsgate, in his recently published book on that harbour, states, that the beach north of Deal advances eastward at the rate of one mile in 60 years. A map of this part of the coast published 60 years ago, is before us, and *Stone End*, (meaning the end of the *shingle beach*, and the commencement of a sand and muddy shore,) is marked thereon, and although 60 years have passed away since the mark was made, *Beach End remains in statu quo.* About 90 years have expired since the commencement of Ramsgate harbour, and therefore according to this gentleman's statement, the beach in the vicinity of Sandwich Haven, during this elapsed time, has advanced towards the mouth of Ramsgate harbour, and in time would block it up, first having placed itself before the entrance of Sandwich harbour.

In a Report of the Commissioners of Ramsgate harbour, made in 1755, they stated "*that from the east there is a drift of large shingle.*" It would be well if recent assertions were sustained by proofs.

Our next fact in this controversy is, that the pebbles composing beaches differ much in quality, colour and size. Those at Dungeness, differ from those at Dover, &c., and therefore the latter cannot be supplied from the former.

Having said what we think is sufficient to expose the error, in the supposition that beach travels from one point to another, let us proceed to show the real extent of *moving beach;* we have already said that the sea takes it up, and lodges it on the shore at an angle of 45°, (the angle at which the wave falls when it does not roll in perpendicular to the shore); this inclination of the wave is aided by the flood tide, which gives the beach so lifted up, an easterly direction on the Kentish coast, inclining with the flood as it does on all other shores. On a change of wind, and with an ebb tide, the accumulating power ceases, and is succeeded by the drawback, or scattering power, and the beach recedes to its former lodgment, going off in the opposite angle or direction—and there it remains till the accumulating power again removes it. This is the extent of a *moving* beach.

A shingle beach is not carried by the drawback wave so far seaward as is a sand beach; the gravity of the latter being more than that of the former, it is drawn often 50 yards beyond the low water mark, and there forms a bank, called by pilots, and beachmen the outer bank, over which it is with much difficulty and danger passed by boats. This is as we have said like the shingle brought up by the accumulating wind and tide, and lodged between high and low water mark, simultaneously along an entire line of coast. The shingle beach at Offordness, (formed similar to Dungeness), along the coast of Norfolk, and Suffolk, round the British Isle, and throughout the world is operated on in a like manner, so that the opinion of travelling or moving beach being peculiar to any particular coast is erroneous. Nature is, we repeat, immutable in her results, acted upon by similar causes throughout the world.

It has been asked how do you account for the increase of beach? Observation has induced us to be of an opinion that there is a progressive principle of accretion in the pebble or shingle. Quite small fine beach is sometimes in great quantities found near the low water mark, and appears to be the nucleus of the larger stone or pebble.

We come now to a question of much importance, and intimately connected with our subject, viz., what is the cause that one convex wave rolling with impetuosity on the shore, and receding back with the like rapidity, leaves behind it a quantity of beach, so that at the end of the flood tide, as the water falls away during the ebb, a large extra accumulation of beach is found up towards the high water mark? But with a change of wind the same formed billow falling on the shore, and receding back to the ocean with the like velocity as the former, takes away with it the beach to a considerable depth, and scours away whatever is within its drawback influence. We ask for a solution of this problem, if buckets of water are thrown on a floor, each produce, as they rush up an inclined plane and fall back again like effects, taking away whatever sand or loose matter is reached by the water—not so with the impinging and receding billows—one has an accumulating, the other a scattering power.*

The subject of moving beach is, indeed, as your intelligent correspondent Nota,† remarks, *connected* with the construction of piers, and into which, as another of your correspondents observes, celebrated engineers have searched in vain, and therefore the lack of correct information on this point is one cause of the failure in improving existing, or in establishing eligible refuge harbours.

Nota has also made some judicious remarks on the subject of the accumulation of mud on the northern shore of the Severn. Whether his hypothesis be correct or not, as to the cause of this, I will not now dispute, but similar operations are in action in all bays and rivers. The deposit on the shores of the Thames is similar every flood tide, that the watermen are obliged during the receding tide, by artificial means to cause an undulation of the water, so that in its drawback course it may take away the deposit of the preceding flood, and keep the shore clean.

Your correspondent speaks of a ship's rudder having been found 10 feet below the level of the shore, while excavating the Bute Dock, Here we have another proof of the progressive accumulation on the margin of the coasts. In the bed of the river Store, in the Island of Sheppy, and in many other parts, the relics of vessels and boats, and also of anchors have been found. Instances have occurred of stranded vessels having been buried between the high and low water mark for many years, and by the effect of the drawback wave have again been uncovered.

Much valuable land has been redeemed from the river Humber by a deposit of mud, a large portion of the rich marsh soil in the vicinity of rivers is an alluvial deposition, and a great part of Holland is the result of this principle in nature, aided by artificial means.

The great geologist Baron Cuvier stated that which we by observation discover to be the fact, viz., that all bays have a disposition to fill up, the water passing along a coast with velocity is charged with matter in suspension, this water or tide falls on the shore inertly, and deposits the mud or that with which it may be charged, so that there is a progressive action proceeding onward, which in time forms the bay into a straight line, and this is often accelerated by the washing down of each point of the crescent which forms the bay. I with deference to your correspondent, we are of opinion that he has confined his exposition of this matter to a local cause, rather then to a general principle.

There is, we humbly submit, a prevalent error in the remarks of your correspondent, who follows Nota, and it is one of those errors which it is most difficult to grapple with, it pervades the minds of pilots, beachmen, &c., viz., the deducing a coincidence from a coexistence, it is of the character of the old tale in endeavouring to connect Tinterton Church with the Goodwin Sand. I do not apply this to him, many of his deductions are correct, but I am sceptical as to the fall of Chalk Cliff west of Dover, being the cause of the diminution of the bar or beach at Dover harbour, if he had watched the effect of the late prevalent winds, he would have seen that this diminishing power was at work many miles east and west of him, from the *North Foreland to the Isle of Wight*, &c., and on the northern and eastern shores; so that he appears to form his opinion "from partial, and not from general laws."

This gentleman asks for a solution of the problem, *i. e.* "the cause of the regular high marks successively following each other on Lydd Beach?" (as it does over other parts of Dungeness), we answer, the same cause that has produced similar effects on other coasts—here again we revert to general laws. It is admitted that each ridge indicates a former high water mark, and that the present high water mark is considerably seaward of those ridges, the inference necessarily is that either the tide does not flow so high as it formerly did, or tha the beach has been raised by some *unusual* flow of the tide, the latter is the solution, and we observe like effects on other shores, &c. Deal Beach from a distance, southward of Walmer, and north of Sandown Castle, including the site on which *Beach Street* at Deal is built, is the largest accumulation of beach we know of, caused by one of those tides we have spoken of, since which no such rise of the tide has occurred, but if we pass further inland in this locality, we find ridges of shingle similar to those at Dungeness. The same effects have been produced on the coasts of Norfolk, and Suffolk, traced out by the like existing proofs.

The site on which stands the town of Great Yarmouth, gives a demonstrative proof of the accuracy of our deductions, it was once a sand in the ocean, called by the Romans, Cerdic sand.

It is a very natural consequence that matter thrown on the shore by an extraordinary rise of the waters of the ocean, should increase its level above the latter, inasmuch as the annually decomposed vegetable matter, (its own produce), &c., tends to cause such an effect. Buildings constructed thereon have after many years been again taken away by the raging wave.

We have only to remark on the subject of the sea advancing most prejudicial on one part of the coast, taking away fields of corn, &c., and receding from another part, that we see similar effects in various parts of the world, and have an opinion on the cause of this, but it might be deemed problematical for the present, therefore we withhold it.

In conclusion, we remark that our globe is progressively under transitions, and while these are going on, we detect the change of substance, but not the principle of destruction.

"See dying vegetables life sustain,
See life decaying vegetates again."

Having lengthened this letter much beyond our intention, we conclude, earnestly and with deference to the opinion of others, by inviting investigtion on the important subject here discussed, and to give it their serious and candid attention, and let it not be forgotten that subjects susceptible of mathematical demonstration are within the solution of educated engineers, but those relating to the change of form of coasts, to the impinging of the wave, effect of currents and tides, and the disemboguing waters are understood only by practical observation, the result of much attention, and long and extensive experience on various coasts.

Henry Barrett.

CATHOLIC CHAPELS—MR. PUGIN—THE INSTITUTE.

Sir—In the Argus newspaper of May 10th, it is stated that "one architect alone, Mr. Pugin, is at present engaged in the erection of no less (fewer) than seventeen Catholic chapels in England." If such be really the case, no wonder that Mr Pugin should be so impressed with the excellence of the Romish, for it seems to have operated almost a miracle in his favour. It would, however, have been more satisfactory, had we been also informed at what places those chapels are, whereas, not one of the seventeen is mentioned by name. Perhaps some of your correspondents will be able to point out such of them as have come to their knowledge. As for Mr. Pugin himself, he seems to be quite satisfied with the notoriety he has earned for himself with his professional brethren, and accordingly does not care to communicate either through your Journal or any other medium, the slightest intelligence of what he has lately done or is actually doing. There never is a single architectural drawing of any kind by him in the exhibitions of the Royal Academy, consequently, if he sends any there at all, they are invariably among the rejected.

Pray, does not the Institute keep some kind of record of all the public works and buildings going on through the kingdom? If it does, you will have little difficulty in ascertaining the correctness of the statement in the Argus; if, on the contrary, it does not keep such historical record, it leaves that undone which would, in time, become a series of valuable documents. To say the truth, it appears to me, and I believe to many others also, that the Institute stands in need of a little filipping to rouse them to some exertion *pro bono publico.* How happens it that only one volume of its Transactions has yet made its appearance? why is it that it has not boldly taken up the subject of competition and its notorious abuses, undeterred by the various difficulties attending any attempt at reform? and why has it not rescued the profession from the Black Hole at the Royal Academy, by establishing an annual architectural exhibition upon a proper and becoming footing? These are questions which, I dare say, you cannot answer personally, but can any one else.

I remain, &c.,

P. S.

ON THE CONSTRUCTION OF OBLIQUE ARCHES.

Sir—In your number for April, p. 116, I observe some observations upon my work on Oblique Bridges, made by an anonymous writer under the signature B. H. B., to which I feel disposed to make a reply, requesting the favour of a place for it in your valuable periodical.

In the first place I wish to premise that I think no author is under the necessity of replying to the criticisms of an anonymous writer, and that it would be more courteous if the writer of a paper professing to be of a scientific character were to put it forth with his name.

B. H. B. in alluding to myself says as follows: "he observes the lines of the courses of the intrados should be made perpendicular to a line drawn between the extremities of the face of the arch, without ever giving any reason for it, or making any remark on the subject farther than that it should be so."

It is quite true that I did not assign a reason for this construction; because it is obviously in order that all the courses may be as nearly as possible at right angles to both faces of the arch, and at the same time parallel to each other. The greatest variation from the rectangular intersection is at the middle of the development, or at the crown of the arch: and at this point where the course is nearly horizontal the variation is of no practical importance or objection: and it may be shewn that it differs from a right angle by an angle whose tangent $= \left(1 - \frac{c}{a}\right) \cot \theta$.

The two methods suggested, proposed, or recommended by B. H. B. to be substituted for the above, are most extraordinary. His second method which he prefers, may be described as a recommendation to build an oblique bridge by *commencing with horizontal courses*, and "summering" them (in workman's phraseology) as the work rises upon the centre. In this way the unscientific ugly old canal bridges were built half a century back. B. H. B. concludes his short dissertation on his proposed improvement in the following words:

"The advantages to be derived from this are, first, that this angle being less than that commonly employed, there will be less tendency to slip; and secondly, that being more nearly perpendicular to the face of the arch, there is consequently more stability."

Every thing herein contained is merely assumed; and most certainly I venture to say that the stability of the oblique arch does not depend upon the courses being laid at right angles to the line *bounding the development*: it is scarcely possible to conceive any thing more rotten than such a construction would prove.

B. H. B. next says, "I am astonished at the serious errors into which Mr. Buck has fallen in his last chapter, which is devoted to *further investigation*, but which had better have been omitted altogether. In attempting to determine at what altitute above the level of the axis of the cylinder the thrust of the arch will be perpendicular to the bed of the voussoir, he gives a formula which produces the strange result that the smaller the arch-stone, the lower will be the said altitude, that is to say, the more secure will be the arch, and also that it will be able to be built at a more acute angle. Another still more strange phenomenon, the result of this formula, is that the greater the skew of the bridge, the less of the arch will have to be supported by iron dowels and bolts: thus an arch built at an angle of 25° will require no assistance from dowels, an arch built at 55° will require to be secured by dowels to a height of 25° above the springing." I will carry the quotation no further, because I shall now proceed to show that "these errors" are attributable to B. H. B. and not to the formula. For the information of those who have not read the work referred to, I will here supply the general formula which I gave for the value of $\sin \tau$, as follows:

$$\operatorname{Sin} \tau = \sqrt{\left\{\left(1 - \frac{r+e}{r} \cos^2 \theta\right) + \left(\frac{a}{2c} \sin^2 \theta\right)^2\right\}} - \frac{a}{2c} \sin^2 \theta$$

In this expression θ is the angle of obliquity, r is the radius of the cylinder, c is the thickness of the arch, and τ is the angle of elevation of the point sought above the axis of the cylinder.

Now if B. H. B. will look attentively at this expression, he will see that its meaning is precisely the reverse of that which he has stated; for instance, "the smaller the arch stone" (or e is taken) the greater will be the value of $\sin \tau$; and this is because e appears only in the *negative* part of the expression. Again, the *greater* the value of e or the thickness of the arch stone, the greater will be the negative part of the expression, and consequently the *smaller* the value of $\sin \tau$: and the lower the point sought at which the thrust of the arch is parallel to its face. And consistently with this, "the greater the skew of the bridge," the greater is the value of $\cos^2 \theta$ which is also found only in the *negative* part of the expression, and consequently the smaller will be the value of $\sin \tau$, and "the less of the arch will have to be supported by iron dowels and bolts" This result of the formula is said to be a "strange phenomenon." I have no doubt it is very startling to the reader, as I know it to be to every practical man at first sight, but it is nevertheless true as I have satisfactorily determined experimentally. I have constructed a model of a portion of an arch at an angle of 25°, which is semicircular on the direct section: this arch stands and keeps its form well without dowels, (although it is but a narrow strip), whereas one made to the same scale at an angle of 45° will not stand at all.

B. H. B. proceeds to say, "the whole of these errors arise from having given the expression $\frac{\operatorname{cosec} \theta \cos \tau}{\frac{1}{2}\pi}$ (nearly at the bottom of page 37) instead of $\frac{\cot \theta \cos \tau}{\frac{1}{2}\pi} \div \operatorname{cosine}(\theta + \phi)$ where ϕ is such an angle that its tangent $= \frac{\cot \theta \sin \tau}{\frac{1}{2}\pi}$. This must be evident to any one who considers that the courses alter their angle with regard to the face of the arch, which Mr. Buck has not taken into consideration."

Here I most readily admit that I had omitted to take into consideration the variable angle at which the courses intersect the face of the arch. I discovered this defect about two months after the publication of the work, and immediately prepared a correction for it, which is as follows. I retain my former notation and the expression for the altitude of the point C′ from which B. H. B. says the error arises, namely $\frac{\operatorname{cosec} \theta \cos \tau}{\frac{1}{2}\pi}$, but in this case I shall substitute its equivalent for the segmental formula, or, $\frac{c}{a} \operatorname{cosec} \theta \cos \tau$, because the equation thence derived is general. I shall now refer to the annexed diagrams: those numbered 28 and 29 are identical with those to be found in my work; that numbered 27 is somewhat different.

Fig. 29. Fig. 28.

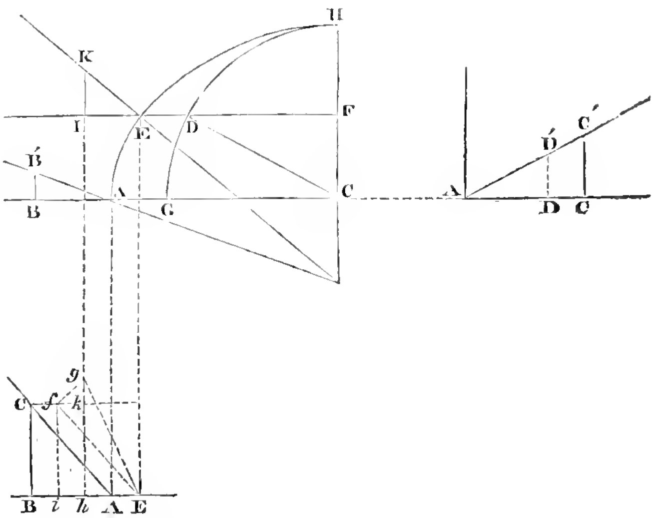

Fig. 27.

Let A B C in the annexed diagram, called fig. 27, represent the plan of the acute quoin of the arch, then when the point A may have ascended to the altitude signified by τ, let us suppose it to be perpendicularly over the point E, fig. 27. Let us also suppose A C fig. 27 which is $\sec \theta$, and CC′ fig. 28, which $= \frac{c}{a} \operatorname{cosec} \theta$ to remain constant, then C′ which is the summit of the tangent CC′, fig. 28, will not be perpendicularly over the point f, fig. 27, (the extremity of E f drawn parallel to A C), but it will be at g; here $f\,g$ is the projection in plan of the tangent C C′; now draw $g\,h$ perpendicular to the face of the arch B A, and to fulfil the conditions $g\,h$ must be a horizontal line, and the distance E h, considered as radius, if multiplied by the tangent of I E K, fig. 29, must be equal to the altitude of g above E, fig. 27, or to $\frac{c}{a} \operatorname{cosec} \theta \cos \tau$. It now becomes necessary to determine an expression for the distance E h, and first E i is equal to A B by construction, therefore E h = E i − $i\,h$, or $(1 - i\,h.)$

$$fg = CC' \times \sin\tau = \frac{c}{a}\operatorname{cosec}\theta\sin\tau,$$

$$\text{and } \frac{c}{a}\operatorname{cosec}\theta\sin\tau \times \sin\theta = \frac{c}{a}\sin\tau = fk = ih$$

$$\therefore\ Eh = (1 - \frac{c}{a}\sin\tau)$$

$$\tan IEK = \frac{\frac{c}{a}\cdot\frac{r+c}{r}\cot^2\theta + \sin\tau}{\operatorname{cosec}\theta\cos\tau}$$

$$\therefore\ (1 - \frac{c}{a}\sin\tau)\left(\frac{\frac{c}{a}\cdot\frac{r+c}{r}\cot^2\theta + \sin\tau}{\operatorname{cosec}\theta\cos\tau}\right) = \text{the altitude}$$

of the tangent at h above E.

Equating these we have

$$(1 - \frac{c}{a}\sin\tau)\left(\frac{\frac{c}{a}\cdot\frac{r+c}{r}\cot^2\theta + \sin\tau}{\operatorname{cosec}\theta\cos\tau}\right) = \frac{c}{a}\operatorname{cosec}\theta\cos\tau$$

Whence we obtain

$$\sin\tau = \pm\sqrt{\left\{\left(\sec^2\theta - \frac{r+c}{r}\right) + \left(\frac{a}{2c}\tan^2\theta - \frac{c}{2a}\cdot\frac{r+c}{r}\right)^2\right\}} - \left(\frac{a}{2c}\tan^2\theta - \frac{c}{2a}\cdot\frac{r+c}{r}\right) \qquad (A)$$

The values of τ for the several cases of obliquity given in my "Essay" are here computed by the formula now given, and for the sake of comparison, the former values are also inserted, as follows:

	By formula now given.	As before given.
When $\theta = 65°$	then $\tau = 38°\ 55'$	27° 17′
55	„ $\tau = 38\ \ 6$	25 13
45	„ $\tau = 36\ \ 35$	21 47
35	„ $\tau = 17\ \ 50$	15 38
25 40′	„ $\tau = 0\ \ 0$	0 0

If the ratio $\frac{r+c}{r}$ were omitted as suggested by B. H. B., the expression would become

$$\sin\tau = \pm\sqrt{\left\{\tan^2\theta + \left(\frac{a}{2c}\tan^2\theta - \frac{c}{2a}\right)^2\right\}} - \left(\frac{a}{2c}\tan^2\theta - \frac{c}{2a}\right) \qquad (B)$$

Now in this equation whatever may be the value of θ, the value of τ remains the same, and when the arc is a semicircle

$$\sin\tau = \frac{c}{a} = \frac{2}{3{\cdot}1416} = {\cdot}63661 = \sin 39°\ 32'\ 24''.$$

This result is in accordance with the speculations of B. H. B., but it is entirely at variance with practice and with correct theory, and so will any formula into which an expression for the thickness of the arch does not enter. The formula A now given contains it, and will be found correct. By this formula $\sin\tau$ continually approximates to, but never reaches $\frac{2}{\pi}$, and vanishes when $\theta =$ either 25° 40′ or 90° as it ought to do.

B. H. B. says, "in finding a term for C O, I would reject the thickness of the cylinder, and consider the point O as that to which the tangents of the small curves, which show in the face of the arch tend: this is more correct, because the joints of the voussoirs being segments of curves there can be no point on the face of the arch at which a ball would roll down the bed in a line exactly parallel to the face; this may be considered too minute for observation, but besides being more correct it will simplify the question much."

Here, I beg to observe B. H. B. is again wrong, and for this reason; these curves of the joints in the face of the arch are all in a vertical plane, and if the thickness of the arch be rejected, they must be regarded as *lines merely*, and a ball would consequently roll down any one of them, or down the chord of any one of them.

My investigation proceeds upon the supposition that the chord of the small curve forms one side of a triangle, the tangent of the intradosal spiral another side, and a line at right angles to the face of the arch, the third side: this triangle must be supposed to exist in the thickness of the arch, and to be parallel to a tangent plane at the point sought, and therefore this is one amongst many reasons why the thickness of the arch should not be rejected, even if it were attended with the advantage stated by B. H. B., namely, that "it will simplify the question much." But instead of simplifying, B. H. B. has produced an equation without explaining how it is obtained, and which he has not been able to reduce to a form for direct solution.

He infers from his equation, "that in all arches of a moderate skew, the point τ is about 40° above the level of the axis of the cylinder;" but I have herein shown that when the thickness is omitted, the point is independent of θ, and always 39° 32′ 24″ above the axis.

Now, although B. H. B., with much complacency, has informed your readers that my last chapter "*had better have been omitted altogether*," I remain of a different opinion. That chapter commenced as follows. "It will naturally be asked to what extent of obliquity is it safe or practicable to construct an arch on the principles herein given? This question we will attempt a solution of, or at least to throw some light upon it." How far I have succeeded it is for others to decide. I am well aware that the subject is not exhausted, inasmuch as I have pursued it further since the publication of the essay, but I have herein confined my remarks to the matter contained in B. H. B.'s communication.

It may be proper to observe, that in all this investigation friction is not taken into account; but friction is an important element in bridge-building, indeed, no arched bridge of masonry would stand without it: if, then, an expression for friction were to enter into the equation, the value of $\sin\tau$ would be very much diminished. And for this reason, my first equation, as given in the "Essay," though not strictly accurate, is practically better than the amended one now given.

Let B. H. B. take up the subject involving friction in his conditions, and he may have an opportunity of rendering considerable service to the engineering profession.

Your obedient servant,

Manchester, May, 1840. GEO. W. BUCK.

ON LIMESTONE IN IRELAND.

An Account of the White Limestone which lies along the Coast of the County of Antrim, in Ireland. By WILLIAM BALD, F.R.S.E., M.R.I.A., &c., June 1837.

WHAT is the white limestone on the Antrim coast?

It is of the same geological composition and formation as the chalk strata in England; but it possesses a characteristic difference in being of much greater induration than in general the English chalk strata; the dynamic unit of the force of crushing, and fracturing it by weight may be taken as equivalent to nearly that under which the Scotch Craigleith sandstone moulders into ruin.

The white limestone lies under the basaltic rock, and in contact with it, it is generally allowed to differ from the chalk of the south of England only in its being of superior induration; the white limestone assimilates to it in the nature and arrangement of the flints, and organic remains which it contains. The flints as mentioned in a former paper, are dark and grey, some of them of a reddish tint. The large nodules of flint are sometimes from eight to twenty inches long. Organic remains occur in the flints; belemnites of the real kind are common, and generally petrified by spar of a calcareous nature and sometimes ammonites.

The white limestone rests on the mulatto, a rock consisting of grains of sand, with specks of green earth. This mulatto rock corresponds with the green sandstone found under the chalk strata in England; it also contains fossil remains.

Under the mulatto rock lies a bluish limestone containing much clay; this rock is analogous to the lias limestone of England, it abounds in animal remains.

Under the lias or blue limestone are beds of marl containing much clay, and in which are beds of gypsum or sulphate of lime (alabaster), and the rock underneath consists of sandstone of a reddish colour.

I have now traced the comparison between the strata connected with the white limestone in Ireland, and the chalk strata in England, so as to leave no doubt whatsoever of their entire and perfect identity with each other. Besides, my friend Dr. Smith, the father of English geology, whom I have known for more than twenty-two years, and who has been in the north of Ireland, and is acquainted with the Antrim limestone, agrees in the description which I have here given of it; further Dr. Smith informed me that the Antrim white limestone was rock of the same formation as Flamborough Head, in England.*

* "*Carbonate of Lime.*—Almost all the varieties of marble and common limestone, together with those earthy concretions that take place in many natural springs and caverns, as also the numerous class of substances called

As to the hardness or induration of the white limestone; I gave a kind of dynamic unit of the labour or ordinary force employed in boring into it for the purposes of blasting, viz., that the force of two men striking with hammers were able to sink into the white limestone at the rate of one foot in depth in half an hour, (jumpers 1¾ of an inch in diameter, hammers about three pounds weight) then the elements employed were the momentum of the hammers, united to the power of the arm, and the time; this is the common labour or force employed. It may be asked what is the amount of it? But to answer this is rather difficult, because one element cannot be perhaps exactly determined, which is the force of the arm united to the momentum of the hammer; but the induration of any rock may be reached or measured in a more exact form; in boring with heavy iron cylinders, and merely working with the simple element of the descending force of the gravitating mass of the iron bar; and the amount of this force may be estimated by the number and length of the descending strokes, using the following formula. The momentum of a body falling is the mass or weight multiplied by the square root of the height it has fallen through and by 8·024.

The number and length of the strokes, and the time occupied would be the measure of the force employed in sinking to any depth in any kind of rock, and this indeed might be used as a standard of comparison to measure the amount of the manual labour employed in boring through all the varieties of rock.

Sir John Robison, the ingenious secretary of the Royal Society of Edinburgh, observes with great truth that much depends on the shape and condition of the cutting point of the bar employed in boring, and also on the goodness of the steel and iron. In operations of this kind approximate results can only be obtained, and these should never be determined, regarding any particular rock, without numerous experiments on all the varieties it would present.

The hardness or induration of rock, as well as its strength to resist crushing by weight are matters of high importance to the engineer; but has any scale yet appeared to measure the amount of these two properties?

The weight which rock can sustain without crushing or fracture, may I think be taken as the amount of its strength. And the measure of its induration or hardness to resist perforation may be determined by the momentum of the descending strokes of an iron bar, and the time employed. The law of the relation of strength compared to hardness may be then traced from these results in all the various kind of rock strata.

What are the causes of the disentegration of the white limestone? *i. e.* the chemical agents which act so powerfully in decomposing its structure? To what cause does it owe its great hardness? If it be ascribed to heat from its close vicinity to the trachyte formations, the lava of the more ancient revolutions, and which I admit is a natural inference; but then on the other hand, I ask to what cause can be ascribed the high induration of the secondary limestone which covers so extensively the plains of Ireland, so far removed from any kind of volcanic remains or formations?

Indeed since the discovery of the carbonic acid gas contained in limestone by the illustrious Dr. Black, the science of chemistry has achieved but little practically in unfolding the chemical properties which give induration to the various strata of the older series, and among which are to be seen the most beautiful, as well as the most imperishable material for engineering works to be found on the globe. Some of these rocks have been wrought at periods so extremely remote that there is difficulty sometimes even to fix the epoch, yet some of them carry on their surface the sharp unimpaired lines of the tool after a lapse of more than three thousand years, and this is fully proved and illustrated in glancing at the granites and sienites employed in the construction of those surprising monuments of Egyptian antiquity, which have astonished all ancient and modern travellers.

calcareous spars, consist almost entirely of lime in chemical combination with carbonic acid or fixed air, the former constituting somewhat less than three-fifths, the latter somewhat more than two-fifths of their whole weight. Hence in scientific language they are called carbonates of lime. The carbonic acid or fixed air may be expelled by heat, or by the addition of any other acid: in the latter case an effervescence takes place, and this effervescence is a very distinctive character of calcareous carbonates, (page 2.)

" Marbles and limestones are with respect to their chemical analysis the same, they differ only in their uses and external character.—(Page 3), *Kidd's Mineralogy.*

In concluding, I find that Mr. Playfair, who ranks so high in the annals of science, has alluded to the black veins which traverse the white granular marble of Carrara having a resemblance to the sutures in the human scull:—are those very remarkable fissures confined alone to the calcareous strata?

It appears that Herm granite is effectually crushed by a pressure of 6·61 tons on the superficial inch; and that a cube of it containing 64 inches weighed 6 lbs. 6 oz., consequently a cubic foot weighs 172·125 lbs., and that there is 13·013 cubic feet to the ton; then it takes 6·61 tons, or 86·11 cubic feet of its own mass to crush one superficial inch, consequently a column an inch square of Herm granite containing 86·11 cubic feet would reach to an elevation of 12,443 feet, or 2 miles and 628 yards high, or 36 times higher than St. Paul's Steeple,* before it would reach its maximum elevation of crushing by its own weight at the base.

Craigleith stone is crushed by about 3 tons weight on the superficial inch,—137½ cubic inches weighed 11 lbs. 10 oz., a cubic foot than 146·094 lbs., being 15·34 cubic feet to the ton, or 46·02 cubic feet of its own mass to crush a superficial inch. A column of Craigleith stone containing 46·02 cubic feet and one inch square would crush at its base by its own weight at the height of 6624 feet, or one mile and 448 yards, being more than 19 times the height of St. Paul's steeple.

A four sided pyramid of Herm granite whose side at the base would be one inch and containing 86·11 cubic feet, would reach an elevation of 37,329 feet, or 7 miles and 123 yards before it would be crushed by its own weight at the base, equal to 109 times the height of St. Paul's steeple.

And a four sided pyramid of Craigleith stone whose side at the base would be one inch, and containing 46·02 cubic feet, would reach an elevation of 19,872 feet, or 3 miles and 1344 yards, before it would be crushed by its own weight at the base, equal to more than 58 times the height of St. Paul's.

PUBLIC BUILDINGS IN LONDON.

A Critical Review of the Public Buildings, Statues and Ornaments in and about London and Westminster—1734.

By Ralph.

[In consequence of this pamphlet being out of print and very scarce, we have deemed it advisable to reprint soch portions as relate to those buildings that still remain undisturbed. Ever since its first appearance, it has always been read by the architect with considerable interest. It was printed anonymously, but it was well known to be by an eminent critic of the day, Ralph, the progenitor of Ralph Redivivus, whose effusions have occupied several numbers of our Journal, and created considerable interest in many of our architectural readers; but since the latter has deserted us, we hope only for a short period, we shall occupy occasionally our pages with some extracts from the above work.]

As nothing contributes more to the grandeur and magnificence of a city, than noble and elegant buildings, so nothing produces a heavier censure on a nation's taste than those which are otherwise; it is for this reason highly laudable to stir up the public to an attention, to such elegant and proper decorations as these, not only in regard to the fame of the people in general, but their interest too. One of the chief reasons why Italy is so generally visited by all foreigners of genius and distinction, is owing to the magnificence of their structures, and their number and variety; they are a continual bait to invite their neighbours to lay out their money amongst them, and one may reasonably assert, that the sums which have been expended for the bare sight of those elegant piles, have more than paid the original charge of their building. This Louis XIV. was sufficiently apprized of when he undertook Versailles, and the company that single fabric only has drawn into France, has made that crown ample amends for the expence of erecting it; and they have both the use and reputation of it still into the bargain.

It is high time, therefore, for us to look about us too, and endeavour to vie with our neighbours in politeness, as well as power and empire. Towards the end of King James I.'s reign, and in the beginning of his son's, taste made a bold step from Italy to England at once, and scarce staid a moment to visit France by the way. From the most profound ignorance in architecture, the most consummate night of knowledge, Inigo Jones started up a prodigy of art, and vied even with his master Palladio himself. From so glorious an out-set, there was not any excellency that we might not have hoped to obtain, Britain had a rea-

* Taking the steeple at 340 feet.

sonable prospect to rival Italy, and foil every nation in Europe beside. But in the midst of these sanguine expectations, the fatal civil war commenced, and all the arts and sciences were immediately laid aside, as no way concerned in the quarrel. What followed was all darkness and obscurity, and it is even a wonder they left us a monument of the beauty it was so agreeable to their natures to destroy.

Wren was the next genius that arose to awake the spirit of science, and kindle in his country a love for that science which had been so long neglected; during his time a most melancholy opportunity offered for art to exert itself in the most extraordinary manner: but the calamities of the present circumstance were so great and numerous, that the pleas of elegancy and beauty could not be heard, and necessity and conveniency took place of harmony and magnificence.

What I mean is this: the fire of London furnished the most perfect occasion that can ever happen in any city, to rebuild it with pomp and regularity; this Wren foresaw, and, as we are told, offered a scheme for that purpose which would have made it the wonder of the world. He proposed to have laid out one large street from Aldgate to Temple-bar, in the middle of which was to have been a large square, capable of containing the new church of St. Paul's, with a proper distance for the view all round it; whereby that huge building would not have been cooped up, as it is at present, in such a manner as nowhere to be seen to advantage at all, but would have had a long and ample vista at each end, to have reconciled it to a proper point of view, and give it one great benefit which, in all probability, it must now want for ever. He farther proposed to rebuild all the parish-churches in such a manner as to be seen at the end of every vista of houses, and dispersed in such distances from each other, as to appear neither too thick nor thin in prospect, but give a proper heightening to the whole bulk of the city as it filled the landscape. Lastly, he proposed to build all the houses uniform, and supported on a piazza, like that of Covent Garden; and, by the water-side, from the Bridge to the Temple, he had planned a long and broad wharf, or key, where he designed to have ranged all the halls that belong to the several companies of the city, with proper warehouses for merchants between, to vary the edifices, and make it at once one of the most beautiful and most useful ranges of structure in the world. But, as I said before, the hurry of rebuilding, and the disputes about property, prevented this glorious scheme from taking place.

In our own times an opportunity offered to adorn the city, in some degree; and though the scarcity of ground in London will not allow as much beauty of situation as one would desire, yet if the buildings were suited to their place, they would make a better figure than they do at present. I have now the late new churches in my eye; amongst all which, there are not five placed to advantage, and scarce so many which are built in taste, or deserve half the money which they have cost; a circumstance which must reflect on the judgments of those who chose the plans, as well as the genius of the architects themselves.

No nation can reproach us for want of expence in our public buildings, but all nations may for our want of elegance and discernment in the execution. In the first place, there are very few of our fine pieces of architecture in sight; they are generally hid in holes and corners, as if they had been built by stealth, or the artists were ashamed of their works; or else they are but essays, or trials of skill, and remain unfinished, till Time himself lays them in ruin. After this, it is unnecessary to mention that our structures are generally heavy, disproportioned, and rather incumbered than adorned; beauty does not consist in expence or decoration; it is possible for a slight building to be very perfect, and a costly one to be very deformed: I could easily name instances of both kinds; but, as I propose to point out to my readers most of the edifices about town that are worth consideration on either side, I will not anticipate my design, but exemplify my meaning, as I proceed, and leave the public to make use of it as they please.

To begin with the remotest extremity of the town; as there were no attempts, till lately, ever made there, to erect any building which might adorn it at all, there was the more necessity to be more particularly careful that the first design of this nature should not miscarry; and yet the four following churches which have been built at Limehouse, Ratcliff, Horsley-down, and Spittal-fields, though they have all the advantage of ground which can be desired, are not to be looked at without displeasure. They are mere Gothic heaps of stone, without form or order, and meet with contempt from the best and worst tastes alike. The last, especially, deserves the severest condemnation, in that it is built at a monstrous expence, and yet is, beyond question, one of the most absurd piles in Europe.

As a fabric of antiquity, it is impossible to pass by the Tower without taking some notice of it, particularly, as it is visited so much by the good people of England, as a place made venerable by the frequent mention which has been made of it in history, and famous for having been the scene of many tragical adventures; but I must caution those of my readers who are unskilled in architecture, not to believe it either a place of strength, beauty, or magnificence; it is large and old indeed, and has a formidable row of cannons before it, to fire on rejoicing days.

The front of the church lately rebuilt in Bishopsgate Street is, I think, more in taste than most about town; the parts it is composed of are simple, beautiful, and harmonious, and the whole deserves to be admired, for pleasing so much, at so little expence.

From hence we may pass on to the South Sea House, and there we shall have some reason to wonder that, when the taste of building is so much improved among us, we see so little sign of it here; at the same expence they might have raised an edifice which would have charmed the most profound judges; beauty is as cheap as deformity with respect to the pocket, but it is easier to find money than genius, and that is the reason so many build and so few succeed.

The tower of St. Michael's, Cornhill, though in the Gothic style of architecture, is undoubtedly a very magnificent pile of building, and deserves very justly to be esteemed the finest thing of that sort in London.

The Monument is undoubtedly the noblest modern column in the world; nay, in some respects it may justly vie with those celebrated ones of antiquity, which are consecrated to the names of Trajan and Antonine. Nothing can be more bold and surprising, nothing more beautiful and harmonious: the bas relief at the base, allowing for some few defects, is finely imagined and executed as well, and nothing material can be cavilled with but the inscriptions round about it. Nothing, indeed, can be more ridiculous than its situation, unless the reason which is assigned for so doing. I am of opinion if it had been raised where Cheapside Conduit stood, it would have been as effectual a remonstrance of the misfortune it is designed to record, and would at once have added an inexpressible beauty to the vista, and received as much as it gave.

The church in Walbrook, so little known among us, is famous all over Europe, and is justly reputed the master-piece of the celebrated Sir Christopher Wren. Perhaps Italy itself can produce no modern building that can vie with this in taste or proportion; there is not a beauty which the plan would admit of, that is not to be found here in its greatest perfection, and foreigners very justly call our judgment in question for understanding its graces no better, and allowing it no higher a degree of fame.

The steeple of Bow church is another master-piece in a peculiar kind of building, which has no fixed rules to direct it, nor is it to be reduced to any settled laws of beauty; without doubt, if we consider it only as a part of some other building, it can be esteemed no other than a delightful absurdity: but if either considered in itself, or as a decoration of a whole city in prospect, not only to be justified but admired. That which we have now mentioned is beyond question as perfect as human imagination can contrive or execute, and till we see it outdone, we shall hardly think it to be equalled.

I think it proper to recommend the steeple of Foster Lane to the attention of the passenger; it is not a glaring pile that strikes the eye at the first view with an idea of grandeur and magnificence: but then the beautiful pyramid it forms, and the just and well-proportioned simplicity of all its parts, satisfy the mind so effectually, that nothing seems to be wanting, and nothing can be spared.

The new church in Old-street is so slight and trifling a building that it is not worth the trouble of a visit; for which reason we shall choose rather to cross over to Smithfield, neglecting the *Chartreux* (Charterhouse), at the same time, because the building is so entirely rude and irregular, that it admits of nothing like criticism: its situation indeed in the midst of a garden is fine, and the square in the front of it is at least kept in better order than most in town.

In Smithfield we shall see a vast area, that is capable of great beauty, but is at present destitute of all; a scene of filth and nastiness, one of the most nauseous places in the whole town; it is true, the use which is made of it as a market is something of an excuse for it, and in some degree atones for the want of that decency which would improve it so much: yet still it is my opinion that ways and means might be found to make it tolerable at least, and an obelisk, pyramid, or statue, in the centre, defended with handsome and substantial rails, would go a great way in so desirable a project.

On one side of this irregular place is the entrance, not the front, of a magnificent hospital; in a taste not altogether amiss, but so erroneous in point of proportion, that it rather offends than entertains; but what is still more provoking, the building itself is entirely detached from the entrance, and though so near a large and noble opening, is in a manner stifled with the circumjacent houses: it is indeed a building in a box or case; and though beautiful in itself and erected at prodigious expence, is so far from giving pleasure to a judge, that he would rather regret its being built at all. It is certain that where

from the North Gallery

Civil Engineer and Architects Journal June 1840

the ground will admit of it, public buildings can hardly be too grand and magnificent; but where they cannot be seen when finished, use and convenience only should be consulted, and a pile of rough stones from the quarry, would answer the end, as well as the marble of Egypt with the decorations of Greece or Rome.

Newgate, considered as a prison, is a structure of more cost and beauty than was necessary, because the sumptuousness of the out-side but aggravates the misery of the wretches within: but as a gate to such a city as London, it might have received considerable additions both of design and execution, and abundantly answered the cost in the reputation of building.

The Physicians College, in Warwick-lane, Newgate-street, (now occupied as a market on the ground floor,) a structure little known and seldom talked of, is a building of wonderful delicacy, and eminently deserves to be considered among the noblest ornaments of this city; and yet so unlucky is its situation, that it can never be seen to advantage, nay seldom seen at all, and what ought to be conspicuous to every body, is known only to a few, and those too people of curiosity, who search out their own entertainments, and do not wait for the impressions of vulgar reports or common fame, to excite their attention or influence their judgments.

The hall of justice at the Old Bailey, and indeed all the courts I have ever yet seen in England are justly to be excepted to, as wanting that grandeur, that augustness, that decency, and solemnity which ought to be inseparable from them, in order to give men in general a suitable awe for the place, and strike offenders with a terror, even more forcible than the sentence they were to undergo. The form of a theatre agrees best with a place of this nature: that part of the building which is the stage, would answer exactly for the bench, the pit for the council, prisoners, &c., and the circle round it, for the spectators: but the present form of these assemblies is utterly opposite to this regularity, and instead of representing the whole in one grand and comprehensive view, divides it into meanness and confusion.

(To be continued.)

PAPIER MÂCHÉ.

Extracts from an Historical Account of the Application of Papier Mâché for Architectural Ornaments. By Charles Frederick Bielefeld. WITH AN ENGRAVING, PLATE XI. *Of the Interior of the Pantheon, Oxford Street.*

[The following account we have selected from the preface to Mr. Bielefeld's work on Papier Mâché ornaments; the subjoined plate shows how far Papier Mâché may be introduced with considerable taste, and a richness of effect produced, which is not so easily obtained by any other kind of ornament at the same expence, besides the facility it affords in being fixed immediately the carpenters' work is finished, and painted directly afterwards.]

"Though paper be one of the commonest bodies that we use, there are very few that imagine it is fit to be employed other ways than in writing, or printing, or wrapping up of other things, or about some such obvious piece of service, without dreaming that frames of pictures and divers fine pieces of embossed work, with other curious moveables, may, as trial has informed us, be made of it."—(Of man's great ignorance of the uses of natural things; Boyle, vol. iii. page 485, ed. M.DCC.LXXII.

Notwithstanding the name that has been given to the material, which would seem to imply that it is of French extraction, there is yet very good reason to believe that to England is to be attributed the merit of first applying this manufacture to important uses. Light and trivial articles, such as snuff-boxes, cups, &c. had, on the Continent, been made of Papier-Mâché for a long course of time; but, from the following passage from an article "sur l'Art de Moulage," in the "Encyclopédie Methodique," we may safely conjecture that here first it was applied to the builder's purposes: "Les Anglois font en carton les ornamens des plafonds que nous faisons en plâtre: ils sont plus durables; se détachent difficilement, ou s'ils se détachent, le danger est nul et la reparation est peu dispendieuse." (Vol. v. Paris, 1788.) We may here take occasion to remark, that the writer of the above passage appears to have perfectly understood the peculiar merits of Papier-Mâché; and it would be impossible to explain more concisely or more accurately than in that short paragraph, the more valuable qualities of this material. The particular circumstances that gave rise to the adoption of Papier-Mâché by the architectural decorator in England, deserves the especial notice of all who are interested in the welfare of our manufactures.

It should be premised, that with the Elizabethan style, or the "rénaissance," of England, enriched plaster ceilings were very generally brought into use, and in the more classic or Italian styles that followed, the same material was still more extensively and more boldly employed. As the art advanced, plaster became partially substituted for carved or panelled wood wainscoting on walls; both in that situation and upon ceilings, foliage of the highest relief and of the richest character, may at the present day be found in the more important edifices remaining of the 17th and beginning of the 18th centuries: these enrichments were generally worked or rather modelled by the hand upon the stucco in its place, whilst still in a soft and plastic state.

As this work had to be done on the spot, and with much rapidity of execution, in order to prevent the stucco from setting before it had acquired the intended form, the art was somewhat difficult; the workman had to design almost as he worked: therefore, to do it well, it was necessary that he should have some of the acquirements and qualities of an artist. This circumstance of course tended very much to limit the number of workmen, and their pay became proportionably large.

It was no unnatural consequence that artisans thus circumstanced assumed a consequence that belonged not to their humble rank in life; it is said that they might have been seen coming to their work girt with swords, and having their wrists adorned with lace ruffles. Such a state of things was, as may be conceived, attended with many inconveniences to their employers; it was scarcely possible to preserve that subordination so essentially necessary in carrying on the business of a builder, and ultimately the workers in stucco, laying aside all restraint, combined together to extort from their employers a most inordinate rate of wages. It would be superfluous here to detail all the circumstances that followed; it is sufficient to state that, as might have been anticipated, the total ruin of their art was the final result of these delusive efforts to promote their individual interests.

Contrivances were resorted to by the masters, which soon supplanted the old mode of working in stucco. The art of moulding and casting in plaster, as previously practised in France, was generally introduced, and the art of preparing the pulp of paper became improved and extended, so as ultimately to render practicable the adoption of Papier-Mâché in the formation of architectural decorations. Thus at last was extinguished the original mode of producing stucco ornaments, and there probably has not been for many years a single individual in England accustomed to that business.

The superior cheapness of the process of casting in plaster brought it into almost universal use; for, although in the course of the last century an immense trade was carried on in the manufacture* of architectural and other ornaments in Papier-Mâché, yet the poverty of taste they generally displayed, and the imperfection of machinery at that time, which prevented this material from coping with plaster in respect to price, ultimately caused its disuse. The manufacturers of Papier-Mâché at that period do not seem to have been aware of the great improvements of which every process of their art proves now to have been susceptible.

A most mischievous effect, however, was produced in the art of decorative designing by this change in the mode of execution. All the deep undercuttings and bold shadows which marked the style of design in the age of Queen Anne, became impracticable when ornaments were to be cast. A meagre, tame, *petite* manner ensued almost of necessity, until by the end of the last century the art of designing architectural ornament had fallen into a deplorable state of imbecility.

The subsequent introduction of Greek ornament formed a new era: the limited capabilities of plaster-casting became then less inconvenient, for the broad, flat character of the Greek style was favourable to the process of casting, and had that manner of designing continued to prevail generally up to the present day, it is probable that no material change would have taken place in the manufacture of ornament. But great fluctuations have occurred in the public taste: the pure and elegant simplicity of Greek ornament is in its nature appreciable only by the more highly cultivated tastes; the generality of persons do not understand its merits; therefore, after the stimulus of novelty had ceased to operate, fashion soon led the public favour into other channels. The bold originality of the Gothic school, the gorgeous and meretricious richness of the Flemish and French schools, the picturesque and fantantic forms of the Elizabethan style, soon found many admirers, and it is this great change in the manner of designing ornament that has given rise to the important improvements in the manufacture of the highly plastic substance called Papier-Mâché. Plaster is totally inapplicable to the exact imitation of the bold florid carvings in the above named styles, whilst to carve in wood all these fanciful forms would occasion a cost far beyond the means of all ordinary purses. As to the putty-composition, a material introduced at the latter end of the last century as a substitute for wood carving in picture frames, &c. its monstrous weight, its brittle, impracticable nature, and the difficulties and heavy expenses necessarily incurred in its manufacture, as well as in fixing it up, render it properly applicable to a very limited range of purposes.

Having made these preliminary remarks upon the origin of Papier-Mâché, and the causes of its improvement and re-introduction, we will proceed to the more important objects of the present brief essay, and describe, for the information of practical men, the mode of applying the material to the various uses for which it is so admirably adapted. We will only premise, that the application of steam power, and the vast improvements that have of late been made in all branches of mechanics, have enabled the present manufacturer to produce a material alike only in name to the Papier-Mâché of the last century: its hard compactness, its strength, its imperishable nature, its tractability (if such an expression may be allowed), the facility with which it may be put together and fixed up, its lightness, the rapidity with which it may be prepared and fixed, and finally its cheapness, are qualities which eminently distinguish it, but which cannot perhaps be fully appreciated but by those who have had extensive experience in its use.

Papier-Mâché is applied to the enriched cornices of bookcases and cabinets, to the mouldings and corners and centre ornaments of paneling on their doors and sides; to the enriched scroll legs of cabinets and pier tables in the old French style; to ornamental brackets for clocks, busts, vases, &c.; to the enriched borders to rooms hung with silk or paper; the ornamental parts for picture and glass frames, no matter how curved and elaborate; also to window-curtain cornices, the canopies of bedsteads, &c. &c. It has been very advantageously used for the latter purpose in the state bed at Chatsworth; and also to the canopy of the Royal Throne in the present House of Lords. For the enrichment of bookcases it is admirably adapted, affording opportunities, if in the Gothic style, of introducing elaborate pinnacles and pendants, rich corbels and pierced frets of open work, deeply undercut rosettes, and spandril and mitre, or intersection ornaments, &c.; also for the exterior cases of organs it has been most advantageously and extensively used: the lightest and most intricate tracery is executed with ease, and an effect produced at a very moderate cost, which by no other means could be obtained without an extravagant expense.

It is needless to add, that when the above mentioned subjects are in classic or other styles, the friezes, the scrolls, consoles, pateras, &c. are among the simplest and most obvious uses of Papier-Mâché.

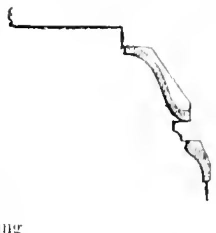
With regard to the mode of fixing Papier-Mâché in cabinet work, perhaps the simplest and yet most accurate rule that can be laid down, is to treat it exactly as if it were wood. It is to be cut with the saw and chisel, and may be bent by steam or heat, planed and cleaned up with sand paper to the smoothest face and to the finest arris, if required; it is to be fastened with brads, needle points, or glue. The larger objects, such as brackets, canopies, &c. can be made either with a wood core, or they can be wholly of Papier-Mâché: in either case, two or three screws at once secure them in their place. When fixed, the work can be painted and grained without any previous preparation whatever; and in gilding, the surface of the work is so much better adapted to receive the gold than that of any other material, that much of the expense and delay usually attendant on the process is saved. The same observation applies to silvering; and it may be added, that there is good evidence (as at Chesterfield House, May Fair, &c.) to prove that the metallic leaf continues untarnished longer on Papier-Mâché than on other substances.

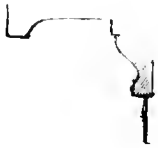
A great variety of brackets, consoles, and cantilevers are made of this substance; indeed, one of the first applications of C. F. Bielefeld's improved Papier-Mâché to architectural purposes, was to form some large consoles and cornices at St. James's Palace on the accession of his late Majesty. Since that time similar work has been fixed up at the Grocers' Hall, the King's College, at the Carlton Club House, the Oxford and Cambridge Club House, British Museum, State Drawing Rooms at Dublin Castle, Grand Lodge Freemasons' Hall, Corn Exchange, &c. Chimney pieces are very effectively decorated in Papier-Mâché, as was formerly much practised by Sir William Chambers and others; specimens of ornamental chimney pieces in the style of Elizabeth and James may be seen in the show rooms. It would, however, be tedious to enumerate all the purposes to which Papier-Mâché can be advantageously applied; it will suffice to repeat, that there is no possible enrichment, in any style, however complicated or elaborate, that may not be readily executed in it. Nor is the manufacturer disposed to limit the application of it to interior work. The improved Papier-Mâché is of too recent introduction to enable us to refer to any example of its use in exterior work further back than about fourteen years; but there are several shop fronts in London that were fitted up at that time, where the Papier-Mâché enrichments are at the present day as sound and perfect as when first turned out of the mould. We may, however, find in the Papier-Mâché of the last century, although of immeasurably inferior quality, abundant proof of its extreme durability in exposed situations. Sir William Chambers's own house in Berners-street, that must be probably three quarters of a century old, has the Papier-Mâché, which enriched the fanciful architecture at the back of the house, in perfect preservation.

At Paris, the Carton-pierre, a substance analogous to Papier-Mâché, but in every way inferior to it, especially as regards its durability, being very absorbent of moisture, and therefore liable to become soft, is largely used for exterior ornaments, even in buildings of the most sumptuous and important character.

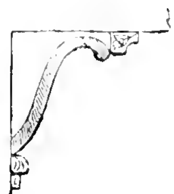
As there is good evidence of the durability of the old Papier-Mâché in the open air, it follows of course, that for interior work its permanency may be still more implicitly relied upon. There are many pier-glass frames, chimney-pieces, &c. composed of this substance, remaining in a perfectly sound good condition, that must have been made early in the last century; and a recent examination of the old Papier-Mâché work at Chesterfield House has most satisfactorily proved, that for ceilings it is equally durable; the component parts are, in fact, such as to render it much less likely to decay than the laths or other work to which it may be attached; and in no instance that has ever come under the observation of the manufacturer, has he detected the least indication of its having been attacked by worms, one of the ingredients used being very obnoxious to them. The Papier-Mâché work now remaining in many houses in London and the country, which was put up in the time of Sir William Chambers, appears, wherever it has been examined, in a perfectly sound state, notwithstanding all those original defects in its composition and manufacture which the manufactory has been able effectually to correct.

It now only remains to give some general instructions for the fixing up of the work. There is one rule which it will be particularly advisable to note, since it is calculated to save much trouble, and secure perfect truth in the fixing of the enriched members of cornices. In running the plain work of a cornice, it should be remembered to provide in the mould a sinking to receive the Papier-Mâché member. If, for example, it is desired to enrich with foliage the cyma of a cornice, the mould should be formed with a sinking thus: or, should it be desired to insert an enrichment, say an ogee and bead, in the bed-moulding of the cornice, a sinking to receive it should be provided thus;

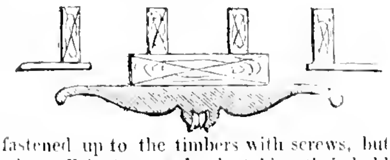




These sinkings need not generally exceed one-eighth of an inch; a raised fillet at the bottom of the enriched moulding would answer the same purpose, the only object being to secure a perfectly continuous and unbroken line.



In cases where a simple cornice would be sufficient, and where it is desirable to have nothing to do with plaster, a small fillet or moulding of wood, nailed to the ceiling and wall with the Papier-Mâché ornament inserted between them, gives a very complete and ornamental finish to the room at a most trifling expense, and without the dirt and delay unavoidably attendant on running plaster mouldings. Where a flower or patera has to be applied to a ceiling, one screw will suffice, unless the patera be of unusual dimensions, to attach it safely to the plaster, taking care that the screws are long enought to reach the joists. Where, however, the flower is intended to cover an opening for ventilation, it will be requisite to block down from the joists; thus screwing the flower to the blocking.



Where ornamental corners are to be applied to a ceiling, they should, if very heavy, be fastened up to the timbers with screws, but generally speaking it would be quite sufficient to use brads, taking their hold on to the laths; this attachment being made still more secure by the use of the cement which is prepared and provided by the manufacturer when required, together with instructions for using it. The same mode of fixing is adopted for frets, friezes, and indeed for all kinds of superficial enrichment, care being at all times taken that brads lay well hold of the laths, for which purpose it is generally expedient to drive the brads in at the hollows, and such parts of the work to be fixed; it is also a useful precaution to drive the brads in a slanting direction, so as to prevent all chance of their drawing. When walls have to be enriched with panels, as is very usual in apartments fitted up in the old French and Italian styles, exactly the same rules for fixing as have been above prescribed for ceilings are to be followed, except that fewer precautions are necessary, as the weight acts differently; where the work is of a very light character even common needle points will be found sufficient, but the cement above mentioned is in all cases an useful addition. With the assistance of the above rules, there is no sort of work in Papier-Mâché that may not be well fitted up by an ordinary joiner.

In drawing up these brief notes on the use of the improved Papier-Mâché, the manufacturer has yet to advert to a new application of it of almost unlimited extent, and one to which a higher degree of importance may justly be attached than any yet described.

There is no art to which the lovers of the Fine Arts, and especially of Sculpture, are more indebted than to the art of moulding and casting in plaster; but for this art we should be almost wholly ignorant of the merits of contemporary sculptors, and the glorious efforts of ancient art would be all but lost to the world. By means of plaster-casts the chef-d'œuvres of all ages are multiplied, and brought from the uttermost corners of the world into the museum of the connoisseur and the studio of the professor.

But how perishable and fragile is a plaster-cast! how cumbrously heavy! how difficult of transport! such indeed are the risks of breakage that no one is willing to pay for a cast, the price that would compensate for the difficulty and expenses necessarily attendant on making a perfect mould and cast. The result is, that the plaster-casts ordinarily sold are most imperfect and unsatisfactory representations of the works of art they are derived from. The new substance now under consideration presents itself to obviate all these inconveniences; for, whilst a copy of any piece of sculpture can be made in it with perfect truth and fidelity, its weight is scarcely one-sixth of that of plaster, and its liability to fracture less than that of stone, marble, or wood.

When these advantages, coupled with economy in price, are considered, it will be easily seen what facilities are now afforded for disseminating throughout the empire a knowledge of the best works of sculpture. The inventor hopes to place within the reach of every individual the enjoyment and advantages derivable from the contemplation and study of the finest specimens of this branch of the Fine Arts.

REVIEWS.

Penny Cyclopædia, Part 87.

We have before directed the attention of our readers, on more than one occasion to this well conducted publication, and now point out the article Paris, on account of the architectural remarks it contains on the principal public buildings, and likewise for the synoptical table which accompanies them, and which is drawn up upon the same plan as those of London and Munich. The arrangement is chronological, and divided into centuries. We extract the latter portion, or that comprising the edifices erected within the present century, more than which we do not consider ourselves at liberty to transfer to our Journal, else we should willingly give the entire table; but whether they take in the work or not, we have no doubt that most of our readers will procure the part containing the article from which our extract is taken.

Nineteenth Century.

	Date.	Architect.	Remarks.
Rue Rivoli	1802	Percier	
La Madeleine	1804-36	Vignon, Huvé, &c.	A Corinthian peristyle of 52 columns (8 at each end) 62 feet high, raised on a stylobate 13 feet high.
Pont des Arts	1804	Cessart & Dillon	For foot-passengers only; arches cast iron, piers stone.
Arch of the Tuileries	1805-10	Percier and Fontaine	Each front has four Corinthian columns (shafts red marble, and bronze capitals), with a central arch and two smaller ones.
Vendôme Column	1806	Gondouin & Lepère	Stone cased with bronze reliefs; total height 141 feet.
Arc de l'Etoile	1806-36	Chalgrin, &c. finished by Debret	Width 147 feet, height 162 feet, depth 73 feet. Arch 47 feet wide, 96 feet high.
Pont des Invalides (Pont de Jena)	1806	Lamandé	Five arches, length 518 feet.
Fontaine du Palmier	1806-8	Bralle	A column on a pedestal, surmounted by a figure of Fame on a globe. Height to top of capital 49 ft. 3 in.: total height, with statue, 56 feet.
Portico, Chamber of Deputies	1807	Poyet	A single range of twelve columns (44 feet high) beneath a pediment.
Bourse	1808-1824	Brogniart & Labarre	A Corinthian peristyle of 64 columns (40 feet high), 14 at each end.
Hôtel des Affaires Etrangères (Quai d'Orsay)	1810-1837	Bonnard and Lecointe	An extensive pile, of which the projecting portion forming the façade towards the quay is 370 feet, and consists of two orders, Doric and Ionic, surmounted by an attic, and each containing 19 large arcades or windows.
Halle aux Vins	1811-13	Gaucher	
Bondy Fountain	1811	Girard	A large circular basin 90 feet in diameter, with other basins or terraces rising from it.
Marché St. Germain	1813	Blondel, M. J. B.	
Chapelle Expiatoire	1815-23	Percier and Fontaine	Tetrastyle portico, Roman Doric attached to a square mass, whose three other sides have semicircular projections crowned by semidomes against the attic of the square part.
École des Beaux Arts	1824-37	Duban and Labrouste	Two Corinthian orders (one in columns, the other in pilasters), upon a basement. The gateway or screen from Château Gaillon, erected in front of the building.
July Column	1833	Alavoine	Pedestal stone, column bronze, total height 154 feet; 13 feet higher than the Vendôme Column.
Pont du Carrousel	1834-6	Polenceau	Timber and iron, with stone piers and abutments. Three arches, centre one 187 feet span, and 16½ rise. Total length 558 feet.
Palais de Justice	1834		Interior remodelled and rebuilt chiefly in the Renaissance style.
Hôtel de Ville	1835	Godde and Lesueur	Restorations, &c. Renaissance style.
Luxor Obelisk	1836		Raised by Lebas, October 25.
Place de la Concorde		Hittorff	Embellished with fountains and architectural decorations.
Notre Dame de Lorette	1825-36	Lebas	Portico, tetrastyle Corinthian.
St. Vincent de Paul		Hittorff and Lepère	
Bazar Bonne Nouvelle	1837	Froehlicher and Grisart	
Church, Faubourg St. Germain	1839	Gau	Gothic.

We should like to see a complete series of such tables for all the principal cities of Europe, published separately, and would suggest this to the writer in the Cyclopædia, with whom the idea appears to have originated.

A Brief Description of the various Plans that have been proposed for supplying the Metropolis with Pure Water, also a short Account of the different Water Companies that now supply London.

The supply of water for domestic use is a subject which, in all times has been regarded as one of great public importance, for, next to the air which we breathe, water is the most powerful agent in vital economy. It is a subject, indeed, which every year becomes of deeper interest, particularly to the inhabitants of a densely peopled metropolis; to vitiated air and vitiated water, and to an insufficient supply of both in purity, is owing the frightful mortality which attacks the inhabitants of towns when compared with those of the country, and we think that the Report of Mr. Farr to the Registrar General, will not do less towards effecting a reform of these evils, than the active agitation of the last ten years, or the labours of parliamentary committees. Much certainly has been done within the last ten years towards improving the supply of water, but much, very much, still remains to be done before the companies can be considered to have done their duty. The author of the pamphlet before us would have done wisely if he had omitted the following passage. "It is not intended, in the present day, that the inhabitants of London, generally, complain of the quality of the water supplied to them, although it still seems to be the policy of certain 'artful and mischievous persons' to use the words of a celebrated individual, now no more, by exaggerated statements to promote contention and inflame the passions of the inhabitants." Though these words are supported by a quotation from the great Telford, we must remember that he was speaking on a subject on which he had strong prejudices. Is it at all probable that the companies would have incurred the enormous outlay which they have done during the last ten years, we may say, within limits, to the tune of a million pounds sterling—if there had not been some truth in the statements of these "artful and mischievous persons," would the Grand Junction Company have removed their works from the "former objectionable site near Chelsea (Sewer?) Hospital" to Brentford, and incurred an expense of nearly £200,000, if it had not been for these "artful and mischievous persons." Our author also subjects himself to the same denomination, for he even has had the *temerity* to tell the Companies that the present mode of filtering as practised by them is insufficient effectually to cleanse Thames water of all the impurities which are suspended in it after heavy rains (vide page 9), and he recommends as the most effectual method, the plan of filtering through charcoal, which we shall hereafter notice. We believe that most of the Companies have done their best in endeavouring to improve their supply from the *Thames*, but whether *that* resort be the best for obtaining water is a subject well worthy of inquiry. We believe it is not disputed, by any party, that water obtained by the aid of deep wells and Artesian boring is far better than obtaining the supply from the Thames, as by the latter, enormous expences are annually incurred in filtering the water, besides the expense of pumping first the supply into a reservoir and thence to the mains, whereas by the former process the water might at once be pumped into the pipes, and forced up to the elevated situation, without the expense, trouble, or delay of filtering, or pumping a second time, but the objections to the former plan have been that a sufficient quantity of water cannot be obtained for this great metropolis, and also that any attempt to obtain a supply by such means would materially affect the numerous wells about the metropolis, particularly those which belong to the manufactories and the large breweries, the latter, until within the last 20 years, were supplied by the various companies, but in consequence of the heavy rental the brewers and manufacturers were compelled to pay, they had recourse to the sinking of wells of great extent, and, we believe, we may say safely, not one of them ever failed affording an ample supply, and if the companies do not take care, their other customers will be obliged to resort to the same means, as very little consideration of the geology of London would be sufficient to convince any one that an abundant supply of water for all, exists in the lower strata, in the same manner as at Paris, a description of which, in one of our recent numbers, will serve to illustrate the present subject.

Before we proceed further with our remarks, however, we must refer to the contents of the pamphlet which has given rise to this notice. The work is published anonymously, but we understand that it is by Mr. Peppercorne, a highly respectable member of the profession, and in no way connected with a gentleman of the same name acting as secretary to one of the metropolitan water companies.

The pamphlet first proceeds to describe the several metropolitan companies, how they obtain their supplies of water and the quality of it. It then details the various plans devised by the water companies, or by private individuals, which are divided into three classes:

1st. Those which propose the purification of the Thames water either by filtration or by subsidence, or by both combined, and which method has been put in practice on an extensive scale by some of the water companies.

2nd. Those which suggest the taking of the water supply from a higher part of the river than where it is now obtained.

3rd. Those which recommend to draw the supply from other sources than the Thames, and to convey it by means of extensive aqueducts to London.

Respecting the first class, it is a well known fact that although filtration through sand, or through sand and gravel, (as in the case of the Chelsea water-works,) produces a perfectly clear and transparent fluid, free from sediment and colour, yet that it is insufficient to free the water from animal or vegetable impurities held in solution, or from any taint which the water may have thereby acquired; but that filtration through charcoal, or through sand and charcoal, as practised to some extent with the water of the Seine at Paris, is capable of removing the whole of the sediment, and also, by a properly regulated system, the entire of the animal and vegetable impurities contained in Thames water taken from the London district.

With respect to the method of subsidence alone in reservoirs, as practised now by almost all the water companies, although a large portion of the muddy sediment contained in Thames water is thereby deposited, yet it is clear that it cannot free the water from all the impurities dissolved in it. The process of subsidence might, it is true, be made to free the water from nearly the whole of the animal impurities contained in it, but in that case the state of rest of the water, to be so purified, ought to continue for a much longer period of time than the companies usually allow, or can afford to allow. It has been ascertained that if Thames water be suffered to remain at rest, completly undisturbed, for a period of several weeks, fermentation will take place in consequence of the presence of animal and vegetable matter, and the liquid will become clear and transparent, with the exception of a small proportion of insoluble sediment, and will lose all unpleasant smell, taste, or colour. This curious fact was ascertained by Dr. Bostock, who communicated the result of his interesting enquiry to the Royal Society in 1829.

Of the second class, it is only necessary to observe, that unless all the water companies, north and south of the Thames, were simultaneously to establish their works as far to the west as at Teddington, no removal to any part within the influence of the tide, could accomplish their intention of supplying a purer water than they now do to the metropolis. * *

In regard to the third and last class of projects that have been submitted to parliament, it is only necessary to state in passing, that the one which seems to have been duly considered by a select committee of the House of Commons so late as 1834, and which was presented by the late Mr. Telford, involves so much difficulty, and the outlay of so exorbitant a capital for the supply of six only out of the eight water companies, that there appears to be no likelihood of its ever being carried into effect. It is not probable, indeed, that any government will authorize the expenditure of £1,200,000 for the construction of two aqueducts, the one sixteen, the other six miles in length, according to Mr. Telford's estimate, in order to bring water *of very questionable purity* from the Verulam and the Wandle to assist *six* only of the water companies of the metropolis.

We shall not stop now to make any inquiry as to the authority, which the author has for stating that the water from the Verulam and Wandle is "of very questionable purity" but shall reserve it until we notice another part of the pamphlet relating to Mr. Telford's evidence.

The author proceeds to give an interesting account of the numerous plans which have been devised since the year 1821, for supplying the metropolis, but as it is not our intention to notice all these schemes, we must confine ourselves to that part which relates to the supply from the Colne near Watford, the locality of the proposed London and Westminster Water Company, now occupying the public attention and a Committee of the House of Lords, and to which the following extracts from the pamphlet alludes.

Among the numerous schemes for the so-called *better* supply of the metropolis with *pure* water, from other sources than the Thames, there are two which at the present time claim particular attention, from an abortive attempt that has been lately made to revive one at least of them. The one of these relates to the supply of the south side of the metropolis from the river Wandle, as proposed in 1834 by Mr. Telford, and the other of the north side from the Colne, also originally suggested by Mr. Telford, but the idea of which was abandoned by him owing to the insignificancy of its stream unless after heavy rains, when its waters were in a very turbid state. (See Mr. Telford's report March 1834, page 3.)

With respect to the water of the Colne, Mr. Telford's experiments clearly proved that this river was totally inadequate in quantity for the supply of even *three* out of the five Water Companies on the north of the Thames, and that with regard to *quality*, it is frequently in so turbid and muddy a state, caused by its flowing over a *red soil*, as to be totally unfit for use.

Mr. Telford indeed gauged *the river* Colne, and the result of his experiments showed that that river was *totally inadequate* for the supply of even *three* out of the five Water Companies on the north of the Thames.

These quotations, unsupported by other parts of Mr. Telford's report and evidence, would naturally, with a stranger to the subject, lead to the belief that the efforts now being made for establishing the proposed company are entirely delusive, and that all their statements are only intended to dupe the respectable individuals who are disposed to lend it their patronage. We have, therefore, thought it necessary to reperuse the reports and evidence, and also at the beginning of last month to visit the spot where the experiments are now being made.

Let us first explain the situation and course of the river Colne. It unites with the Thames near Isleworth, in its course to Watford, it receives several tributary streams; from Watford it proceeds (still under the name of the Colne) for a distance of about four miles, through Otters Pool, the scene of the company's experiments, and Bushey Mills, the place from which Mr. Telford proposed to take his supply, it then goes on to the place at which the river Verulam falls in; the Colne continuing on as a very small stream beyond this spot, to the north-east, towards Colney and South Mims, and the larger stream, the Verulam, proceeding to the north by St. Alban's, for some distance up the country—therefore it will be observed that the river is called the Colne from its junction with the Verulam to the river Thames. When Mr. Telford stated that the Colne is an insignificant stream, &c., it may be clearly seen by his evidence, that he alluded to that part of the stream above its junction with the Verulam, and he proposed to divert that part of the Colne, so as to prevent it from affording any supply to the intended water-works at Bushey Mills, on the banks of the Colne, but lower down the river, and that in his report he called that part of the river Colne from the junction of the two rivers to Watford "the Verulam," whereas as we have already shewn, it is called "the Colne." We will now give a few extracts from the evidence of Mr. Telford to show that at that part of the Colne "Bushey Mills," there was an ample supply of pure water to be obtained in the driest season without filtration, or pumping, sufficient to supply the principal part of the metropolis. All this evidence the author has carefully kept out of view, for what purpose we will not pretend to say, unless from a misunderstanding of Mr. Telford's evidence.

Mr. Telford in his report to the Lords of the Treasury, February 1834, states, that after having examined the streams which fall into the river Thames in the vicinity of London, he found an abundance of pure, transparent water, within the distance of 16 miles on the north (of London), amply sufficient for the supply of three of the present companies on that side of the Thames, he then goes on to state that the eastern branch (of the Colne) called the Verulam, a transparent stream, occupies the St. Alban's Valley, and about half way between St. Albans and Watford, the Colne joins the Verulam; but, unless after heavy rain, the Colne is an insignificant stream, and at such time very muddy, wherefore it is intended to exclude the Colne from furnishing any part of the supply of water.

Mr. Telford farther states in this report that "at Watford Mill" (near the spot the proposed company intend to erect their works), "in the autumn of 1833, being the driest season, as regards the supply of rivers, experienced during the last half century, the Verulam river produced upwards of 30 cubic feet of water per second; being more than double the quantity supplied by the three companies in the year 1828, namely, 13 cubic feet per second;" and as a farther proof, to show that Mr. Telford proposed taking his supply from near the spot, the proposed company have selected, he says, "Immediately above the commencement of the intended London Aqueduct, about two miles above Watford, the valley of the river Verulam affords a commodious situation for extensive reservoirs of water, and for allowing it to settle, if such should hereafter be deemed requisite. From this place a covered aqueduct may be made to descend with a uniform inclination of 18 inches per mile to Primrose Hill, terminating in a set of extensive receiving and distributing reservoirs, at the height of 146 feet above high water Trinity."

This report is again supported by the subsequent evidence of Mr. Telford, given in the report from the select committee of the House of Commons, 1834, from which we select the following.

23. What part of the River Verulam do you take the first portion of your supply from?—The supply is taken about half way between Watford and St. Albans; the whole supply for the north side is taken there.

24. Is it from a place called Grove Mill?—No, we do not take any from Grove Mill; Bushey Mill is the place. We make no use of the waters of the Gade. There are six paper-mills immediately above Grove Mill.

29. With reference then to the River Verulam, you think that, as it would only be necessary to apply it to the districts now served by the three companies at the west end of London, that the River Verulam would supply a quantity sufficient?—Quite so; for what I have estimated is without reservoirs; but from the usual summer supply of the river, a great deal might be added if it were necessary; perhaps a third more by making reservoirs for retaining flood water in that valley, but at present that is not wanted, because the quantity in the dryest season known for thirty years, was upwards of 30 cubic feet per second, which is more than double what the three companies have now.

35. There is no other part of the Colne according to your opinion then that would furnish an improved supply to London, except this River Verulam, which you would take unpolluted, at the point of junction with the Colne?—Below the junction of the Colne. We must divert the Colne. The Colne has in summer time very little water in it; we could not get a cubic foot of water per second; in rainy weather there is a considerable quantity, but as it passes through a red soil, it is very muddy, and therefore we must divert it, and never let it go into the River Verulam at all, until it has passed the point where the London aqueduct is taken off.

36. But alluding to those delta streams which the various sources commonly called the Colne eventually form, is it your opinion that any of those branches are sufficiently pure and good for the supply of London?—The Verulam is the only one.

37. No other branch of the Colne is sufficiently good for the supply of London?—No, not the Colne.

69. Then none of the branches of the Colne which appear to lay more conveniently near to London, are, in your opinion, fit for the supply?—Not so fit as the Verulam by any means.

70. Not in point of purity of water, nor being able to get high service?—Just so; those were the two reasons that struck me.

71. Did you propose to make a covered aqueduct?—Yes, I did.

87. Where does the Verulam fall into the Colne?—It falls in about half way between Watford and St. Albans.

88. Are you aware of any ornamental sheets of water upon the Colne below the point at which you propose to divert the water by the aqueduct for the supply of London?—No, I am not.

89. Did you search to ascertain whether there were any or not?—There were none occurred to me.

90. The Committee observe that the stream which is commonly called the Colne, from St. Albans down to Watford, until it arrives at Otter's Pool, is not, in point of fact, the river which you mean by the Verulam?—Yes, the St. Albans river is the Verulam.

91. You have stated that in dry weather that smaller branch which is called the Colne, and which flows in the neighbourhood of Otter's Pool, has very little water?—It had not a cubic foot per second when we measured it twice.

92. Well then, in dry weather every seat which is below Otter's Pool must feel the abstraction of this River Verulam, every seat between that and the Thames?—No doubt of it.

93. Will you tell the Committee the minimum of water that runs down the Verulam at the place where you propose to take from it?—Thirty cubic feet was the minimum.

94. In what time?—Per second.

95. Will you also tell the Committee what is the largest quantity or the maximum quantity of water that you expect would be necessary to supply the metropolis?—I recommend to take the power of the whole 30 feet.

96. But in your Report you have stated the supply at present of the metropolis to be about 13 feet from those three companies?—Yes.

1334. Why do you recommend the plan of taking the water either from the Verulam or from the Wandle, in preference to taking it from Richmond, provided there is filtration in both instances; provided both are filtered, why should you prefer taking it from the Wandle and the Verulam in preference to taking the water from the Thames at Richmond?—In the first place the appearance of the water of both the Wandle and Verulam was very tempting, being remarkably pure and transparent; and in the next place, as I have already stated, my plan saves both filtering and pumping.

1335. Would not the expense of the aqueduct more than equal the expense of filtering and pumping s—I think it is a more natural way of supplying the water than having recourse to artificial means, if you can get it.

1336. There is no objection to use artificial means to accomplish any object?—No.

1337. Do you not, in fact, by your plan, really buy the power in the shape of compensation to the mill owners?—We do.

1338. And that power is already possessed and in existence in the shape of steam-engines, by the present company?—Yes.

1339. Will you tell the Committee in your own way why we ought to prefer this at the expense of £1,200,000?—It would be a much more perfect scheme with respect to supplying the town, and much less objectionable to the people.

1340. In what less objectionable?—Because there are many strong objections to the use of Thames water.

1341. Without referring to the prejudice against the Thames water, what would be your recommendation, supposing there was no such prejudice?—*I should recommend my own plan as being the best.*

1342. Is it not infinitely more expensive?—Yes, more expensive, I dare say.

1343. Would it not increase very much the expense which we are now put to for water in the metropolis?—It might to a small extent; but the metropolis should certainly enjoy the purest water that can be procured.

1344. That would not be desirable?—Not if you can be well served without it, certainly.

1345. Can you say it will not be as well supplied without that expense by taking it from Richmond?—I do not think so good a supply could be got at Richmond.

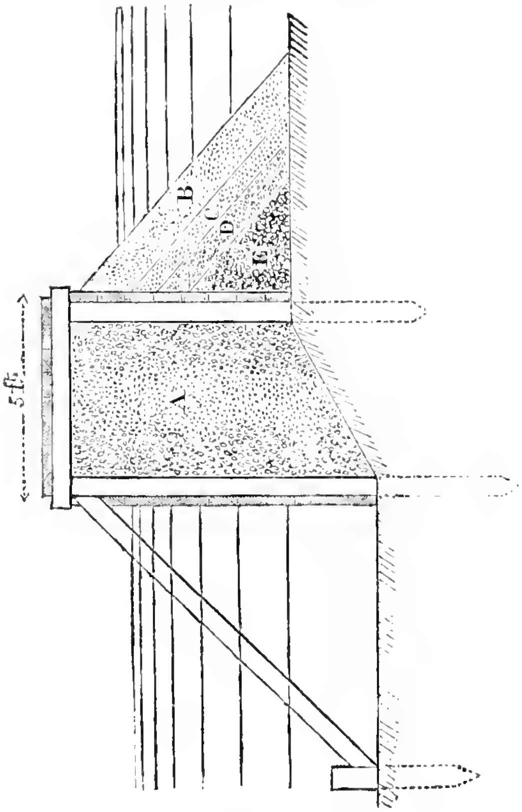
1346. If the companies would deliver the Richmond water filtered, would you say it was an objectionable supply?—Filtering takes out only what is mechanically suspended in the water, not what is dissolved.

From these extracts, we think there is ample testimony to show that a very copious supply of pure water may be obtained from that part of the Colne (called by Telford the Verulam), at Bushey Mills, for serving a large portion of the metropolis. Now it is near this spot that the promoters of the Company are carrying on their experiments, not intending at present to take the supply from the river itself, but from borings down to the springs, from which as the appearance of those already reached will show, in several parts of the Valley at a distance of nearly a mile from each other, the water rises to within 18 inches of the surface, and thus it is expected an ample quantity of water will be obtained, independent of the river Colne or Verulam, sufficient to supply the greater part of the metropolis without at all affecting the river. The Company are determined fairly to test the experiments for this purpose, and are now erecting a steam engine to ascertain what quantity of water can be really obtained. From the evidence of Mr. Telford already given as to the river coupled with the supply from borings, it appears beyond a doubt that an abundance of excellent water can be obtained without filtering or pumping. We think that the promoters are deserving of praise for the exertion which they are now making to bring the question to an issue, and if they can show that a large supply can be obtained sufficiently to provide water for at least three of the companies, it will be a great boon, not only to the public, but to the companies themselves, as we conceive it would be to the interest of all parties, that the old companies should take their supply from the new company, and thereby save the great and heavy expences of pumping and filtering which they are now obliged to adopt; as according to the evidence of Mr. Telford the new company will be able to supply the water in London at an elevation of 146 feet above Trinity datum, a height quite sufficient for the highest eistern of any part of London to be served by gravity.

We have extended our notice to a greater length than we originally intended, but the importance of the subject has led us on imperceptibly, we must therefore defer further notice of this interesting pamphlet, which affords abundance of materials for consideration—before we conclude we shall give the description of a proposed filtering apparatus designed by the author, and another which has been adopted in Switzerland.

PROPOSED FILTERING APPARATUS.

Section of Filterer.



REFERENCE.

A, charcoal medium (the finest in the centre). B, fine sand. C, coarse sand. D, fine gravel, and pebbles. E, large gravel, and broken pottery.

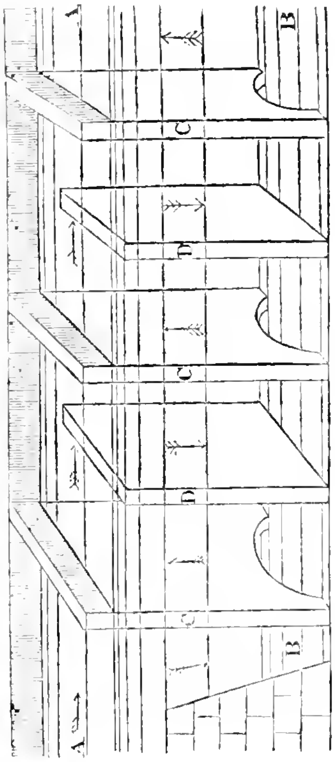
The above is a sketch of a filtering apparatus, in which charcoal is proposed to be employed, both in a fine and coarse state, the finest being in the centre, as shown. In this case, lateral filtration by a head of water, is to be preferred to an extended surface over which the filtering materials are laid, and where the water percolates through, as in the first place, the materials, (the charcoal in particular,) will be more accessible at all times for cleansing, or renewing, when required. The charcoal, in fact, might be taken out and renewed, without interfering in the slightest way with the rest of the filtering materials, being separated from the gravel and sand, by the perforated planking, as shown in the sketch.

In the next place, the disposition of the sand, &c., the finest being placed outermost, at its natural slope of about 30° or 35°, would in a great measure supersede the necessity for having the surface scraped frequently, as done at the Chelsea water works, for there would be a *natural tendency*, in proportion as the outer layer of sand became loaded with the sediment and particles which it would arrest, for the sand to *slide down* to the base of the slope, where the sediment, &c., would accumulate, and from whence it might be easily removed. All that would be required in that case, would be to renew occasionally the outer layer of sand, which might be done with the greatest ease from the top of the filter-bank, without disturbing the remainder. It should be observed that where the sand comes in contact with the planking near the top of the structure, the planks should be laid with a close joint, to prevent the sand from being washed through.

Thirdly, the proposed method would be far less expensive, as regards the first cost, than the method of filtering by descent; as the construction of the frame-work would be entirely of timber, it could be put together by any carpenter at a trifling expense. The plan proposed would, in fact, combine the advantages of two distinct filters, acting in very different ways, with very little more trouble or expense, than would be involved in the construction of one only. With respect to the length of time during which the charcoal would retain its purifying qualities, it appears from Mr. Lowitz's experiments, before mentioned, that charcoal retained its antiputrescent properties *for a whole year*; and therefore, if the supply had to be renewed but once in that time, the expense would be but small. This must be, however, a matter of experiment; probably it might be found that by removing the charcoal from time to time, washing it well, and *exposing it to the light and air*, for a few days, it would part with whatever putrescent particles it had absorbed from the water, and might be made use of over again.

In order to facilitate the deposition and subsidence of the grosser impurities and sediment, previous to the water passing through the above filter-bank, a very simple and ingenious method might be employed, which has been put in practice with complete success in Switzerland, for purifying a stream of water, and which was described by Sir Henry Englefield, in the Philosophical Journal, so far back as 1804. It consists of a structure of timber or masonry, as shown in the perspective sketch below, where A A is the upper surface of the stream to be purified, and B B the bottom. The channel, or cut through which the water flows is divided into several chambers by the parallel partitions C, C, C, alternately rising above the surface level of the stream, and *open at the bottom*, while the intermediate partitions D, D, do not rise *within several feet* of the surface, and are continued to the bottom. It is obvious that the course of the water must be in the direction of the arrows, and in this repeated slow ascent and descent, all floating impurities will be left at the top, while the sediment and heavier impurities will subside to the bottom. The sediment, &c., may be easily removed and the apparatus cleansed, by sending down persons between the walls, and the operation would be facilitated by giving to the bottom of the cut or canal, the form of an inverted arch. The spaces between the partition walls might be partly filled with coarse filtering materials, such as broken pottery, or coarse gravel and pebbles, &c.

Filter used in Switzerland.



Illustrations of Indian Architecture from the Muhammadan Conquest downwards, by Markham Kittoe, Esq. Calcutta: Thacker & Co., 1838. London: Allen.

We presume that Mr. Kittoe is not a member of the profession, but attached to the civil service in India, but he has produced a work which cannot but be valuable both to the student of this specific branch of architecture, and to those who are attached to the art in general. The buildings represented in the numbers before us, principally belong to the end of the seventeenth century, and their details are illustrated with an accuracy, which makes them equally useful and interesting. It is singular to trace in the buildings of Delhi or Agra some of the commonest ornaments of our own drawing rooms, and Mr. Kittoe's work presents variations of them which might be introduced with advantage here. Some of the trellis work in stone is particularly admirable, and would look extremely well in iron, or applied for grained ceilings, the variations of honeysuckle ornament are also well worthy of attention. These numbers are indeed a great accession to our stock of works on ornament, and Mr. Kittoe deserves the highest praise for producing a work so valuable in despite of all the difficulties of the Indian press. To us this work is also gratifying as it is a proof of our labours having penetrated there and been appreciated, and we cannot but recommend to architects and amateurs in the different parts of our empire to imitate Mr. Kiltoe's excellent example, there is plenty of field in Malta, the Ionian Isles, Aden, our vast Indian empire, and during the several military expeditions. Much might be done by such observations to increase our stock of architectural works.

RICAUTI'S *Rustic Architecture.* London: Weale, 1840.

The first number of this work opens with the design and details of a cottage in the Elizabethan style, which, if it be a fair specimen of its successors, is highly promising. We are glad to see the taste which exists among our nobility for the erection of ornamental farm buildings, and publications of this nature are highly calculated to promote it. The example of the late Duke of Sutherland on his estates in Staffordshire, we trust, will have a lasting effect.

LITERARY NOTICE.

Mr. Jobbins has published a Map of the Environs of London, 30 miles round, at a scale of 3 miles to the inch, with the railways delineated, which for cheapness and completeness can vie with any.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL SOCIETY.

Jan. 16.—J. W. LUBBOCK, Esq., V. P. and Treasurer, in the Chair.

A paper was read entitled, "*On Nobili's Plate of Colours,*" in a letter from J. P. Gassiott, Esq., to J. W. Lubbock, Esq., V. P. and Treasurer.

The effect produced by the late Sig. Nobili, of inducing colours on a steel plate, excited the curiosity of the author, and led him to the invention of the following method of producing similar effects.—Two of Professor Daniell's large constant cells were excited with the usual solutions of sulphate of copper and sulphuric acid. A highly polished steel plate was placed in a porcelain soap-plate, and a filtered solution of acetate of lead poured upon it. A piece of card board, out of which the required figures had been previously cut with a sharp knife, was then placed upon the steel plate. Over the card, and resting on it, there was fixed a ring of wood, a quarter of an inch thick, and the inner circumference of which was of the same size as the figure. A convex copper plate was made, so that its outer edge might rest on the inner part of the wooden ring; and its centre placed near, but not in actual contact with, the card board. Connexion was then made by the positive electrode of the battery with the steel plate; the negative being placed in the centre of the copper convex plate. The figure was generally obtained in from 15 to 35 seconds. If a concave, instead of a convex plate be used, the same colours are obtained as in the former experiment, but in an inverse order.

Jan. 23.—SIR JOHN BARROW, Bart. V. P., in the chair.

The Rev. John Pye Smith, D.D., was elected a Fellow.

A paper was read entitled, "*On the structure of Normal and Adventitious Bone.*" By Alfred Smee, Esq.

"*An attempt to establish a new and general Notation, applicable to the doctrine of Life Contingencies.*" By Peter Hardy, Esq.

After premising a short account of the labours of preceding writers, with reference to a system of notation in the mathematical consideration of life contingencies, the author enters at length into an exposition of the system of symbols which he has himself devised, together with the applications which they admit of in a variety of cases.

Jan. 30.—J. W. LUBBOCK, Esq., V.P. and Treasurer, in the Chair.

James Annesley, Esq., was elected a Fellow.

A paper was read, entitled "*Observations on Single Vision with two Eyes.*" By T. Wharton Jones, Esq.

The author animadverts on the doctrine which Mr. Wheatstone, in his paper on the Physiology of Binocular Vision, published in the Philosophical Transactions for 1838, p. 371, has advanced, in opposition to the received theory of single vision being dependent on the images of objects falling on corresponding points of the two retinæ. He maintains that, under these circumstances, the two impressions are not perceived by the mind at the same instant of time, but sometimes the one and sometimes the other. If one impression be much stronger than the other, the former predominates over, or even excludes, the other; but still the appearance resulting from the predominating image is, nevertheless, in some manner influenced by that which is not perceived. He supposes that there are compartments of the two retinæ, having certain limits, of which any one point or papilla of the one corresponds with any one point of the other, so that impressions on them are not perceived separately; and considers that this hypothesis, combined with the principle above stated, is required, in order to explain the phenomena in question.

Feb. 6.—J. W. LUBBOCK, Esq., V.P. in the Chair.

John Parkinson, Esq., and the Rev. Charles Pritchard, M.A., were elected Fellows.

A paper was read, entitled "*Observations on the Blood-corpuscles of certain species of the genus Cervus.*" By George Gulliver, Esq.

Feb. 13.—The Marquis of Northampton, President, in the Chair.

Martin Barry, M.D., and Joseph Phillimore, LL.D., were elected Fellows.

The paper entitled "*Experimental Researches in Electricity; 16th series:*" by M. Faraday, Esq., D.C.L., the reading of which had been commenced at the last meeting, was concluded.

Feb. 20.—The MARQUIS of NORTHAMPTON, President, in the Chair.

J. Caldecott, Esq. was elected a Fellow.

The following paper was read:—

"*On the Wet Summer of* 1839." By L. Howard, Esq. The observations of the author were made at Ackworth, in Yorkshire; and the following are his results, with regard the mean temperature and the depth of rain, in each month, during 1839:—

	Mean temperature.	rain in inches.		Mean temperature.	rain in inches.
Jan.	37·04	1·13	July,	59·30	5·13
Feb.	39·64	2·44	Aug.	58·09	2·94
March,	39·08	3·21	Sept.	54·49	3·13
April,	44·09	0·58	Oct.	48·39	3·40
May,	49·94	0·38	Nov.	43·44	4·54
June,	56·35	4·89	Dec.	37·29	1·85

Mean temperature of the year 47·21°.
Total depth of rain, in 1839, 33·62 inches.

He states that the climatic mean temperature of the place is about 47°, and the mean annual depth of rain about 26 inches. The excess of rain during the year 1839, was, therefore very great. The author describes the effect of the hurricane of the 7th of January, and follows the changes of the weather during the remainder of the year.

March 5.—The MARQUIS of NORTHAMPTON, President, in the Chair.

Captain John Theophilus Boileau, was elected a Fellow.

The reading of a paper entitled, "*On the Chemical Action of the Rays of the Solar Spectrum on Preparations of Silver and other Substances, both metallic and non-metallic; and on some Photographic Processes,*" by Sir John F. W. Herschel, Bart. &c., was resumed and concluded.—The object which the author has in view in this memoir is to place on record a number of insulated facts and observations respecting the relations both of white light, and of the differently refrangible rays, to various chemical agents which have offered themselves to his notice in the course of his photographic experiments, suggested by the announcement of M. Daguerre's discovery. After recapitulating the heads of his paper on this subject, which was read to the Society on the 14th of March 1839, he remarks, that one of the most important branches of the inquiry, in point of practical utility, is into the best means of obtaining the exact reproduction of indefinitely multiplied fac-similes of an original photograph, by which alone the publication of originals may be accomplished; and for which purpose the use of paper, or other similar materials, appears to be essentially requisite. In order to avoid circumlocution, the author employs the terms *positive* and *negative* to express, respectively, pictures in which the lights and shades are the same as in nature, or as in the original model, and in which they are the opposite; that is, light representing shade; and shade, light. The terms *direct* and *reverse* are also used to express pictures in which objects appear, as regards right and left, the same as in the original, and the contrary. In respect to photographic publication, the employment of a camera picture avoids the difficulty of a double transfer, which has been found to be a great obstacle to success in the photographic copying of engravings or drawings. The principal objects of inquiry to which the author has directed his attention in the present paper, are the following.

1. The means of fixing photographs; the comparative merits of different chemical agents for effecting which, such as hyposulphite of soda, hydriodite of potass, ferrocyanate of potass, &c., he discusses at some length; and he notices some remarkable properties, in this respect, of a peculiar agent which he has discovered.

2. The means of taking photographic copies and transfers. The author lays great stress on the necessity, for this purpose, of preserving, during the operation, the closest contact of the photographic paper used with the original to be copied.

3. The preparation of photographic paper. Various experiments are detailed, made with the view of discovering modes of increasing the sensitiveness of the paper to the action of light; and particularly of those combinations of chemical substances which applied either in succession or in combination, prepare it for that action. The operation of the oxide of lead in its saline combinations as a mordant is studied; and the influence which the particular kind of paper used has on the result, is also examined; and various practical rules are deduced from these experiments. The author describes a method of precipitating on glass a coating possessing photographic properties, and thereby of accomplishing a new and curious extension of the art of photography. He observes, that this method of coating glass with films of precipited argentine, or other compounds, affords the only effectual means of studying their habitudes on exposure to light, and of estimating their degree of sensibility, and other particulars of their deportment under the influence of reagents. After stating the result of his trials with the iodide, chloride, and bromide of silver, he suggests that trials should be made with the fluoride,

from which, if it be found to be decomposed by light, the corrosion of the glass, and consequently an etching, might possibly be obtained, by the liberation of fluorine. As it is known that light reduces the salts of gold and of platinum, as well as those of silver, the author was induced to make many experiments on the chlorides of these metals, in reference to the objects of photography; the details of which experiments are given. A remarkable property of hydriodic salts, applied, under certain circumstances, to exalt the deoxidating action of light, and even to call into evidence that action, when it did not before exist, or else was masked, is then described.

4. The chemical analysis of the solar spectrum forms the subject of the next section of his paper. It has long been known that rays of different colours and refrangibilities exert very different degrees of energy in effecting chemical changes; and that those occupying the violet end of the spectrum possess the greatest deoxidating powers. But the author finds that these chemical energies are distributed throughout the whole of the spectrum; that they are not a mere function of the refrangibility, but stand in relation to physical qualities of another kind, both of the ray and of the analyzing medium; and that this relation is by no means the same as the one which determines the absorptive action of the medium on the colorific rays. His experiments also show that there is a third set of relations concerned in this action, and most materially influencing both the amount and the character of the chemical action on each point of the spectrum; namely, those depending on the physical qualities of the substance on which the rays are received, and whose changes indicate and measure their action. The author endeavoured to detect the existence of inactive spaces in the chemical spectrum, analogous to the dark lines in the luminous one; but without any marked success. The attempt, however, revealed several curious facts. The maximum of action on the most ordinary description of photographic paper, namely, that prepared with common salt, was found to be, not beyond the violet, but about the confines of the blue and green, near the situation of the ray F in Fraunhofer's scale: and the visible termination of the violet rays nearly bisected the photographic image impressed on the paper: in the visible violet rays there occurred a sort of minimum of action, about one-third of the distance from Fraunhofer's ray H, towards G; the whole of the red, up to about Fraunhofer's line C appears to be inactive; and lastly, the orange-red rays communicate to the paper a brick-red tint, passing into green and dark blue. Hence are deduced, first, the absolute necessity of perfect achromaticity in the object-glass of a photographic camera: and secondly, the possibility of the future production of naturally coloured photographs.

5. The extension of the *visible* prismatic spectrum beyond the space ordinarily assigned to it, is stated as one of the results of these researches; the author having discovered that beyond the extreme violet rays there exist luminous rays affecting the eyes with a sensation, not of violet, or of any other of the recognized prismatic hues, but of a colour which may be called *lavender-grey*, and exerting a powerful deoxidating action.

6. Chemical properties of the red end of the spectrum. The rays occupying this part of the spectrum were found to exert an action of an opposite nature to that of the blue, violet, and lavender rays. When the red rays act on prepared paper in conjunction with the diffused light of the sky, the discolourating influence of the latter is suspended, and the paper remains white; but if the paper has been already discoloured by ordinary light, the red rays change its actual colour to a bright red.

7. The combined action of rays of different degrees of refrangibility is next investigated; and the author inquires more particularly into the effects of the combined action of a red ray with any other single ray in the spectrum; whether any, and what differences exist between the joint, and the successive action of rays of any two different and definite refrangibilities; and whether this action be capable, or not, of producing effects, which neither of them, acting alone, would be competent to produce. The result was that, although the previous action of the less refrangible rays does not appear to modify the subsequent effects produced by the more refrangible; yet the converse of this proposition does not obtain, and the simultaneous action of both produces photographic effects very different from those which either of them, acting separately are capable of producing.

8. In the next section, the chemical action of the solar spectrum is traced much beyond the extreme red rays, and the red rays themselves are shown to exercise, under certain circumstances a blackening or deoxidating power.

9. The author then enters into a speculation suggested by some indications which seem to have been afforded of an absorptive action in the sun's atmosphere; of a difference in the chemical agencies of those rays which issue from the central parts of his disc, and those which, emanating from its borders, have undergone the absorptive action of a much greater depth of his atmosphere; and consequently of the existence of an absorptive solar atmosphere extending beyond the luminous one.

10. An account is next given of the effect of the spectrum on certain vegetable colours, as determined by a series of experiments, which the author has commenced, but in which the unfavourable state of the weather has, as yet, prevented him from making much progress.

11. The whitening power of the several rays of the spectrum under the influence of hydriodic sals, on paper variously prepared, and previously darkened by the action of solar light. The singular property belonging to the hydriodate of potash of rendering darkened photographic paper susceptible of being whitened by further exposure to light, is here analyzed, and shown to afford a series of new relations among the different parts of the spectrum, with respect to their chemical actions.

12. The Analysis of the Chemical Rays of the Spectrum by absorbent media, which forms the subject of the next section, opens a singularly wide field of inquiry; and the author describes a variety of remarkable phenomena which have presented themselves in the course of his experiments on this subject. They prove that the photographic properties of coloured media do not conform to their colorific character: the laws of their absorptive action as exerted on the chemical, being different and independent of those on the luminous rays: instances are given of the absence of any darkening effect in green and other rays of the more refrangible kind, which yet produce considerable illumination on the paper that receives them.

13. The exalting and depressing power exercised by certain media, under peculiar circumstances of solar light, on the intensity of its chemical action. This branch of the inquiry was suggested by the fact, noticed by the author in his former communication, that the darkening power of the solar rays was considerably increased by the interposition of a plate of glass in close contact with the photographic paper. The influence of various other media, superposed on prepared paper, was ascertained by experiment, and the results are recorded in a tabular form.

14. The paper concludes with the description of an *Actinograph*, or self-registering photometer for meteorological purposes: its objects being to obtain a permanent and self-comparable register and measure, first, of the momentary amount of general illumination in the visible hemisphere, which constitutes day-light; and secondly, of the intensity, duration, and interruption of actual sunshine, or, when the sun is not visible, of that point in the clouded sky behind which the sun is situated. In a postscript, dated March 3rd, 1840, the author states that he has discovered a process by which the colorific rays in the solar spectrum are made to affect a surface properly prepared for that purpose, so as to form what may be called a *thermograph* of the spectrum; in which the intensity of the thermic ray of any given refrangibility is indicated by the degree of whiteness produced on a black ground, by the action of the ray at the points where it is received at that surface, the most remarkable result of which is the insulation of *heat-spots* or thermic images of the sun quite apart from the great body of the thermic spectrum. Thus the whole extent over which prismatic dispersion scatters the sun's rays, including the calorific effect of the least, and the chemical agency of the most refrangible, is considerably more than twice as great as the Newtonian coloured spectrum. In a second note, communicated March 12, 1840, the author describes his process for rendering visible the thermic spectrum, which consists in smoking one side of very thin white paper till it is completely blackened, exposing the white surface to the spectrum and washing it over with alcohol. The thermic rays, by drying the points on which they impinge more rapidly than the rest of the surface, trace out their extent and the law of their distribution by a whiteness so induced on the general blackness which the whole surface acquires by the absorption of the liquid into the pores of the paper. He also explains a method by which the impression thus made, and which is only transient, can be rendered permanent. This method of observation is then applied to the further examination of various points connected with the distribution of the thermic rays, the transcalescence of particular media, and the polarization of radiant heat (which is easily rendered sensible by this method), &c. The reality of more or less insulated spots of heat distributed at very nearly equal intervals along the axis of the spectrum (and of which the origin is *probably* to be sought in the flint glass prism used—but *possibly* in atmospheric absorption) is established. Of these spots, two of an oval form, are situated, the one nearly at, and the other some distance beyond the extreme red end of the spectrum, and are less distinctly insulated; two, perfectly round and well insulated, at greater distances in the same direction; and one, very feeble and less satisfactorily made out, at no less a distance beyond the extreme red than 422 parts of a scale in which the whole extent of the Newtonian coloured spectrum occupies 539.

A paper was also read entitled, "*Remarks on the Theory of the Dispersion of Light, as connected with Polarization.*" By the Rev. Baden Powell, M. A. Since the publication of a former letter on the same subject, the author has been led to review the theory in connexion with the valuable illustrations given by Mr. Lubbock of the views of Fresnel: and points out, in the present supplement, in what manner the conclusions in that paper will be affected by these considerations.
